a. Description. Wind is air in motion and results from differences in atmospheric pressure. A wind is described by its direction and speed. The direction of a wind is the direction from which it is blowing. A wind coming from the north, for example is termed a north wind. As reported in observations, wind direction is determined with reference to true north and is expressed to the nearest 10 degrees. Thus, a direction of 090 degrees (a wind from due east) would be reported as 09. Wind velocities are reported by the Air Weather Service in knots. A table of wind speeds and their specifications is given (table 1) to aid in estimating speeds. Over irregular terrain, a wind does not move with a steady force or direction, but as a succession of gusts and lulls of variable speed and direction. These eddy currents, caused by friction between air and terrain, are called gusts or turbulence. Turbulence also results from unequal heating of the earth's surface, the cooler air of adjacent areas rushing in to replace the rising warm air from heated areas. Usually the turbulence produced by surface friction is intensified on a sunny afternoon.

b. Systems. Local pressure and wind systems are created by valleys, mountains, and land masses that change the weather characteristics of areas. Since land masses absorb and radiate heat more rapidly than water masses, the land is heated more than the sea during the day and cools more at night. In coastal areas, warm air over the land rises to a higher altitude and then moves horizontally out to sea. To replace this warm air, the colder air over the water moves on to the land, creating the so-called sea breeze. The circulation is reversed at night, so that the surface air moves from the land to the sea, resulting in a land breeze.

Table 1. Weather Map Scale of Wind Velocity

Descriptive item	Knots	Meters/seconds	Specifications
Calm	less than 1	0–0.2	Calm; smoke rises vertically.
Light air	1–3	0.3–1.5	Direction of wind shown by smoke drift but not by wind vanes.
Light breeze	4–6	1.6–3.3	Wind felt on face; leaves rustle.
Gentle breeze	7–10	3.4–5.4	Leaves and small twigs in constant motion; wind extends light flag.
Moderate breeze	11–16	5.5–7.9	Raises dust and loose paper; small branches are moved.
Fresh breeze	17–21	8.0–10.7	Small trees in leaf begin to sway; crested wavelets form on inland waters.
Strong breeze	22–27	10.8–13.8	Large branches in motion; whistling heard in telegraph wires; umbrellas used with difficulty.
Near gale	28–33	13.9–17.1	Whole trees in motion; inconvenience felt when walking against wind.
Gale	34–40	17.2–20.7	Breaks twigs off trees; generally impedes progress.
Strong gale	41–47	20.8–24.4	Slight structural damage occurs (chimney pots, slates and shingles removed).
Storm	48–55	24.5–28.4	Seldom experienced inland; trees uprooted; considerable structural damage occurs.
Violent storm	56–63	28.5–32.6	Very rarely experienced; accompanied by widespread damage.
Hurricane	64 and over	32.7 and over	

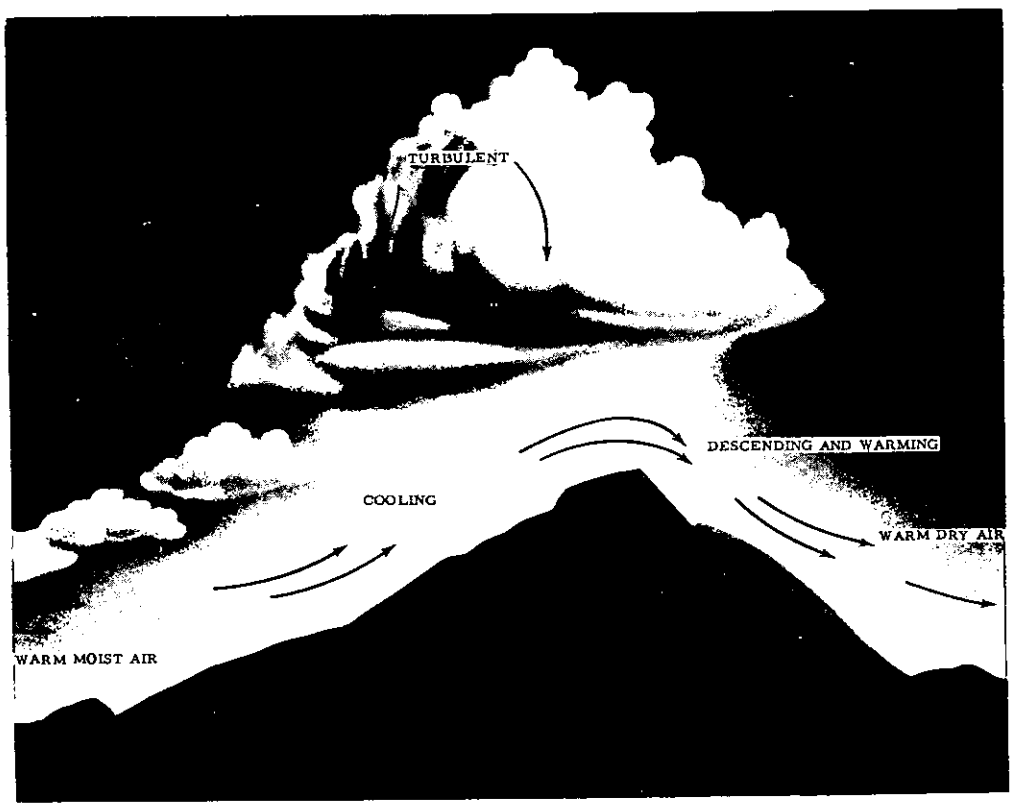

Figure 1. Chinook or foehn effect.

c. Vally Wind. Heated by the daytime sun, the air in contact with a mountain slope becomes lighter than the surrounding air and rises up the slope, being replaced by denser, colder air. This air movement is called a valley wind because it appears to be flowing up from the valley. At night the air in contact with the slope becomes colder and more dense, sinking down along the slope to create a mountain breeze that seems to flow out of the mountain. Mountain breezes generally are stronger than valley winds, especially in the winter.

d. Chinook. A chinook (North America) or foehn (Europe) (fig. 1) is a phenomenon that occurs in winter and spring on the lee or downwind side of mountain ranges over which there flows a steady crosswind of moisture-laden air. As the air rises over the windward side of the mountains it expands and cools rapidly, producing clouds and precipitation. As the air moves down the lee side of the mountain range it compresses and warms. As a result, there are warm, dry winds on the lee side of the mountains.

e. Fall and Gravity. Fall and gravity winds are caused by the descent of downslope air through the action of gravity. They are typical of the Greenland coast, which is essentially a high plateau sloping abruptly to the sea along an irregular coastline cut by many fiords. The central plateau area remains ice-covered throughout the year, developing extremely cold air masses which frequently drain off through the fiords to the sea and attain a near-hurricane speed. At sea level the winds remain relatively cold and very dry. Similar winds are the bora, which drain off the southern Alps and the Balkan Plateau into the Adriatic Sea, and the mistral of the Rhone Valley in France.

f. Monsoon. A monsoon wind is any seasonally changing or reversing wind. It is strongest and steadiest on the southern and eastern sides of Asia. It blows outward from high-pressure centers overland toward the sea in winter and inward toward low-pressure overland in summer. In most regions, the summer monsoon season is generally characterized by extensive cloudiness and frequent precipitation. The winter monsoon season is characterized by dry air and infrequent cloudiness except where the monsoon winds pick up moisture by moving over warm seas before striking an island or peninsular coastline.

28. Humidity

a. Vapor. Water vapor is the most important constituent of the atmosphere that determines weather phenomena. Although the oceans are the primary source, a limited amount of water vapor also is furnished to the atmosphere from lakes and rivers, snow, ice fields, and vegetation. The percentage of water vapor by volume in the air may vary from practically zero in deserts to 4 or 5 percent in humid tropical areas.

b. Amount. Humidity is the term used to describe the amount of water vapor in the air. The amount that the air actually contains compared with what it could hold at a given temperature and pressure is termed the relative humidity. When a specific air mass holds all the moisture that it can at a given temperature, it is described as having a relative humidity of 100 percent.

c. Dew Point. The dew point is that temperature at which the air becomes saturated. The higher the dew point, the greater amount of water vapor the air can hold. The closer the dew point temperature is to the actual temperature, the greater the likelihood of condensation. Condensation results when the capacity of the atmosphere to hold water is reduced by cooling, so that the water vapor in the air is changed to visible moisture such as fog or clouds.

29. Clouds

a. Classification. Clouds are masses of condensed moisture suspended in air in the form of minute water droplets. They are classified according to their form or appearance and by the physical processes producing them. The Air Weather Service reports the type of clouds present, the heights of the cloud bases and cloud tops, the amount of cloudiness, and the direction in which the clouds are moving. Cloud amounts are reported in terms of the fraction of the sky that is covered by clouds (fig. 2). The following terms are used:

(1) *Clear.* No clouds, or less than 0.1 of the sky covered.

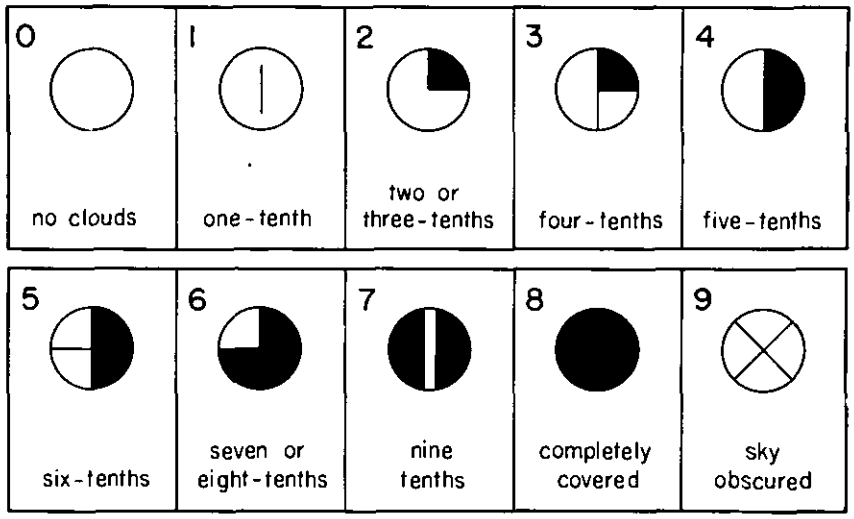

Figure 2. Cloud cover symbols.

(2) *Scattered.* 0.1 to 0.5 of the sky covered.
(3) *Broken.* 0.6 to 0.9 of the sky covered.
(4) *Overcast.* More than 0.9 of the sky covered.

b. Heights. Cloud heights are reported in meters above the ground. The heights of clouds below 1,500 meters (5,000 feet) are reported to the nearest 30 meters (100 feet); clouds from 1,500 to 3,000 meters (5,000 to 10,000 feet) are reported to the nearest 150 meters (500 feet), and clouds above 3,000 meters (10,000 feet) to the nearest 300 meters (1,000 feet). A ceiling is defined as the lowest layer of clouds that is reported as broken or overcast and not classified as thin. Heights of clouds are reported in meters or feet above the point of observation.

c. Direction. Cloud direction is the direction toward which the cloud bases are moving. It is reported according to the eight points of the compass.

d. Appearance. According to their appearance, clouds are either cumiliform or stratiform. Cumiliform clouds are formed by rising currents in unstable air. Stratiform clouds result from the cooling of air in stable layers.

(1) Cumiliform clouds are dense with vertical development. The upper surface of a cumiliform cloud is dome-shaped, while the base is nearly horizontal. Usually clouds of this type are separate from each other and rarely cover the entire sky. The precipitation from cumiliform clouds generally is showery in nature.

(2) Stratiform clouds usually occur in layers that may extend from horizon to horizon, without the vertical development of cumiliform clouds. Precipitation from this type of cloud usually is in the form of light continuous rain, drizzle, or snow.

e. Groupings. Clouds may be grouped into four families (fig. 3)—

(1) *High.* Cirrus, cirrostratus, cirrocumulus.
(2) *Middle.* Altostratus, altocumulus.
(3) *Low.* Stratus, nimbostratus, stratocumulus.
(4) *Vertical development.* Cumulonimbus for an example.

f. High Clouds. High clouds usually occur at heights of from 6,000 to 12,000 meters (20,000 to 40,000 feet), although they may be found at much lower altitudes in polar regions. They are composed of ice crystals. The characteristics of the major cloud types in this group are as follows:

(1) *Cirrus.* This is a delicate white fibrous cloud that often appears bright yellow or red from the reflection of light from a rising or setting sun. Cirrus

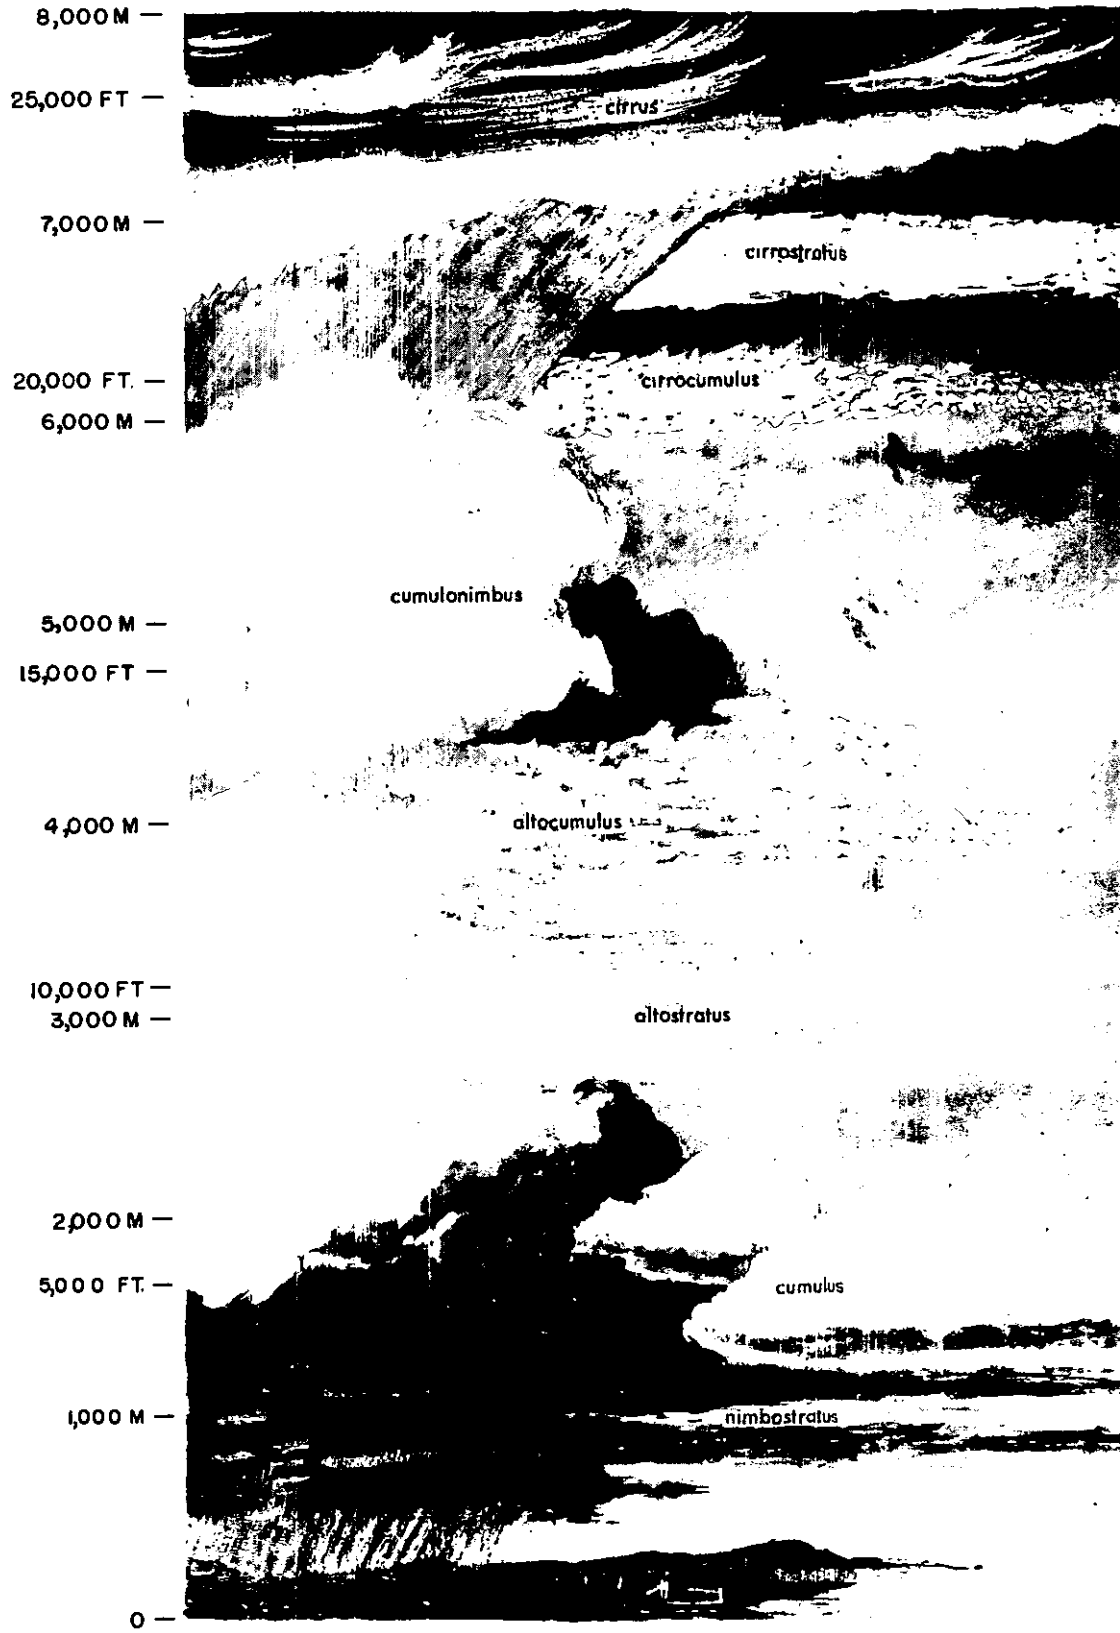

Figure 3. Major cloud types.

clouds may appear as isolated tufts, featherlike plumes, or streaks with upturned ends often referred to as mare's tails. Because of. their thinness, cirrus clouds do not blur the outlines of the sun or moon, and usually do not make an appreciable change in the appearance of the sky.

(2) *Cirrostratus.* These are thin, whitish veils of clouds that give the sky a milky look. Usually they can be distinguished from cirrus clouds by the halo which light from the sun or moon produces in them.

(3) *Cirrocumulus.* Clouds of this type consist of patches of small, rounded masses or white flakes arranged in groups or lines.

g. Middle Clouds. Middle clouds usually occur at altitudes of 1,800 to 6,000 (6,000 to 20,000 feet) meters in the lower limit of this range in the colder seasons, and at altitudes near the upper limit in the warmer seasons. The major types are—

(1) *Altostratus.* Clouds of this type appear as a veil of gray or bluish fibrous clouds, the thinner forms resembling the thicker forms of cirrostratus. Altostratus clouds are associated with smooth or stable air layers, and occasionally they produce light rain or snow.

(2) *Altocumulus.* This cloud type can appear as a layer or in patches, is white or gray in color, and the cloud elements appear as rounded masses or rolls. They occur in a variety of forms, and may exist at several levels at the same time.

h. Low Clouds. Low clouds usually have bases below 1,800 meters (6,000 feet) and include the following types:

(1) *Stratus.* These form a low layer resembling fog, although they do not rest upon the surface. They give the sky a hazy appearance. The base of this cloud is usually rather uniform in height but it often occurs in the form of ragged patches or cloud fragments. Layers of stratus clouds may cover hundreds of thousands of square miles. Usually they are thin, and range in thickness from a few hundred feet to several thousand feet. Frequently, stratus clouds are accompanied by fog, haze, or smoke between their bases and the ground. Visibility is very poor under stratus clouds, and precipitation from them usually is in the form of light snow or drizzle.

(2) *Nimbostratus.* Clouds of this type form a low, dark gray layer. Precipitation usually is in the form of continuous rain or snow of variable intensity. Because of its thickness, sometimes more than 4,500 meters (15,000 feet), the nimbostratus is frequently classified as a cloud of vertical development.

(3) *Stratocumulus.* This type of cloud forms a lower layer of patches of rounded masses or rolls. The base of the stratocumulus usually is higher and rougher than the stratus clouds. Frequently these clouds change into the stratus type.

i. Vertical. Vertical development clouds cannot be classified according to height, since they extend through all the levels assigned to other cloud groups. The bases vary from 150 to 3,000 meters (500 feet to 10,000 feet) or higher, while the tops may vary from 450 meters (1,500 feet) to more than 12,000 meters (40,000 feet). They all occur in relatively unstable air and frequently are associated with strong vertical currents and intense turbulence. In this category are the following:

(1) *Cumulus.* Clouds of the cumulus type are dense, with vertical development. The base is horizontal and uniform in height above the earth, with a top that is domed or cauliflower-like in shape. Cumulus clouds appear white when they reflect sunlight toward the observer, but when viewed from directly underneath or when they are between the observer and the sun, they may appear dark with bright edges. Over land, cumulus clouds tend to develop during the warming of the day, dissipating at night when the

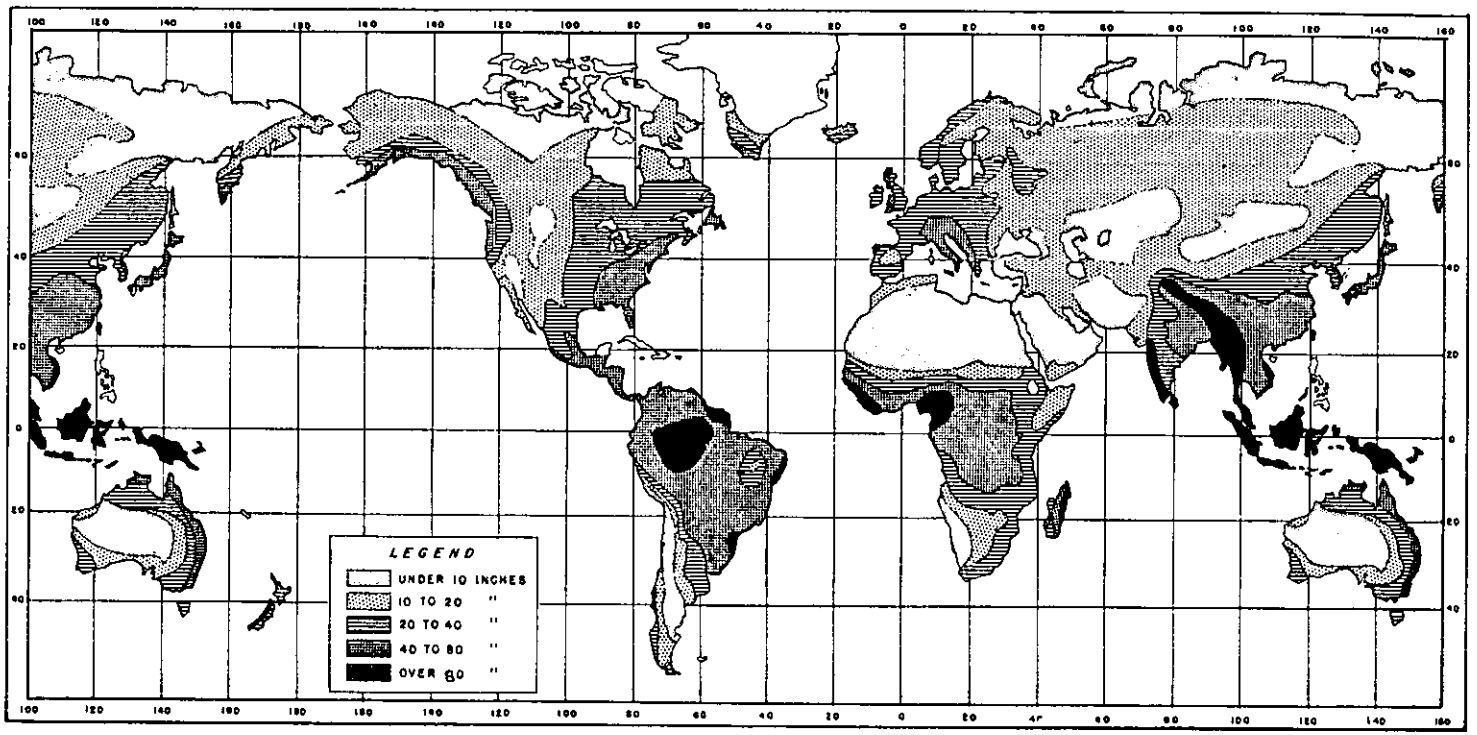

Figure 4. World rainfall.

earth's surface cools. Over water, cumulus clouds tend to develop at night as the water surface remains warm while the air mass cools slightly.

(2) *Cumulonimbus.* Clouds of this type are heavy masses which extend to great heights. Their upper portions resemble mountains or towers capped with a fibrous texture. They develop only in unstable air. Cumulonimbus clouds are distinguished from cumulus clouds chiefly by the veil of ice crystal clouds which surrounds their upper portions. Thunderstorms, squalls, turbulence, and hail are characteristic of cumulonimbus clouds.

30. Precipitation

a. Description. Precipitation (fig. 4) is visible moisture that falls from the atmosphere, such as rain, sleet, snow, hail, drizzle, or combinations of these. As an air mass rises, its ability to hold moisture decreases and clouds form. When the cloud droplets become too large to remain in suspension, rain occurs or if the air temperature is below freezing, snow is formed. Sleet is frozen rain formed by droplets passing through a layer of below-freezing air. Hail consists of rounded particles composed of layers of ice falling from cumulonimbus clouds with strong updrafts. Raindrops are carried to high altitudes and frozen into ice pellets. They then fall and are carried up again by the updraft until the weight of the pellet is greater than the force of the updraft, whereupon it falls to earth. Freezing rain falls from the air in liquid form but freezes upon contact with objects on the surface that are at a temperature below the freezing point. The ice formed on these surfaces is called glaze. Air Weather Service observations include information on the form of precipitation and its character, intensity, and amount.

b. Character. The character of precipitation refers to its duration and to changes in its intensity. It is reported as continuous, intermittent, or showery. Continuous precipitation is that in which the intensity increases or decreases gradually. Intermittent precipitation is characterized by a gradual change in intensity, but ceases and recommences at least once an hour. Showery precipitation is marked by rapid changes in intensity and by starting and stopping abruptly. The intensity of precipitation is determined on the basis of its rate of fall. It is described as follows:

(1) *Very light.* Scattered drops or flakes which do not completely wet an exposed surface, regardless of duration.

(2) *Light.* Not more than 0.25 millimeter (0.01 inch) in 6 minutes.

(3) *Moderate.* 0.26 to 0.75 millimeter (0.01 to 0.03 inch) in 6 minutes.

(4) *Heavy.* More than 0.75 millimeter (0.03 inch) in 6 minutes.

c. Intensity. The intensity of snow and drizzle is determined on the basis of the reductions in visibility which result, as follows:

(1) *Very light.* Scattered drops or flakes which do not completely wet an exposed surface, regardless of duration. Negligible effect on visibility.

(2) *Light.* Visibility 1 kilometer (5/8 statute mile) or more.

(3) *Moderate.* Visibility less than 1 kilometer (5/8 statute mile), but not less than 1/2 kilometer (5/16 statute mile).

(4) *Heavy.* Visibility less than 1/2 kilometer (5/16 statute mile).

d. Amount. The amount of precipitation is expressed in terms of the vertical depth of water (or melted equivalent in the case of snow or other solid forms) accumulated within a specified time on a horizontal surface. This is expressed to the nearest 0.25 millimeter (0.01 inch). A depth of less than 0.13 millimeters (0.005 inch) is called a trace. In the case of snow, both the actual depth and the equivalent in water are required. Snow depth is measured to the nearest whole inch, and less than 1.3 centimeters (0.5 inch) is termed a trace. The water equivalent of snow is determined by melting a representative sample and measuring the resulting depth of water. As an average figure, 25 centimeters (10 inches) of snow are considered to be equivalent to 2.5 centimeters (1 inch) of water, although this is subject to wide variation. The depth of snow is of concern in estimating the trafficability and the water equivalent is significant for

problems involving water supply, flood prediction, stream flow, and drainage.

31. Fog

Fog is defined as a mass of minute water droplets suspended in the atmosphere at the surface of the earth that reduces horizontal visibility. It is formed by the condensation of water vapor in the air. The most favorable conditions for the formation of fog are an abundance of water vapor, high relative humidity, and a light surface wind. A light wind tends to thicken fog. Increasing wind speeds will usually cause fog to lift or to dissipate. Fog usually is more prevalent in coastal areas than inland because there is more water vapor in the atmosphere. Inland fogs may be very persistent in industrial regions. In most areas of the world, fog occurs more frequently during the colder seasons of the year than it does in the warmer seasons.

32. Storms

a. Thunderstorms. A thunderstorm is a local storm accompanied by thunder, strong gusts of wind, heavy rain, and sometimes hail, usually lasting for no more than an hour or two. A thunderstorm is cellular, each of its many cells having violent up and down drafts in close proximity. The overall mass has a characteristic frontal zone with violent cool winds racing inward toward the storm in spite of its forward motion. When a thunderstorm reaches its mature stage and the rain begins, a downdraft starts in the lower and middle levels of the storm. This large body of descending air causes strong, gusty surface winds that move out ahead of the main storm area, often resulting in a radical, abrupt change in wind speed and direction termed the first gust. In general, the strongest thunderstorm winds occur on the forward side of the storm where the downdraft first reaches the surface. These winds ascend upward at various rates, depending on the intensity and size of the storm. The actual storm has layers conducive to icing and hail formation depending on the altitudes obtained by updrafts and so on. The speed of a thunderstorm wind may reach 80 to 120 kilometers (50 to 75 miles) per hour for a short time.

b. Tornadoes. Tornadoes are circular whirlpools of air which range in size from about 30 meters to .8 kilometer (100 feet to one-half mile) in diameter. A tornado appears as a rotating funnel-shaped cloud extending toward the ground from the base of a cumulonimbus. The low pressure and the high wind speeds encountered in the center of the tornado are very destructive. The paths of tornadoes over the ground usually are only a few miles long and the tornadoes move at speeds of 40 to 90 kilometers (25 to 55 miles) per hour. Although the maximum wind speeds associated with tornadoes never have been measured directly, property damage and other effects indicate that they may exceed 800 kilometers (500 miles) per hour. When they occur over water, tornadoes are termed *waterspouts.*

c. Tropical Cyclones. A tropical cyclone is a low-pressure system of cyclonic winds that forms over tropical water areas (fig. 5). Cyclones of great intensity are called hurricanes in the Atlantic and Eastern Pacific Oceans, typhoons in the Western Pacific Ocean, cyclones in the Indian Ocean, and *willi willi* in Australia. The average life span of a tropical cyclone is 6 days, although some last only a few hours and others as long as 2 weeks. Tropical cyclones of hurricane intensity are characterized by extremely strong and gusty surface winds, with speeds of 117 to more than 240 kilometers (73 to more than 150 miles) per hour; continuous intense rain in the central area, and a relatively calm area near the center known as the eye. These storms vary in size from 80 to 800 kilometers (50 to 500 miles) in diameter. The precipitation associated with tropical cyclones is extremely heavy. They are frequently accompanied by violent thunderstorms, with the heaviest rainfall usually occurring some distance ahead of the eye of the moving cyclone. Abnormally high tides are a common companion of hurricanes and are responsible for a great amount of damage.

33. Weather Forecasts

a. Factors. A weather forecast is a prediction of the weather conditions expected to occur at a place, within an area or along a route at a specified future time. The accuracy and reliability of weather forecasts depend upon a number of factors, including the climatic characteristics of the forecast area, the amount

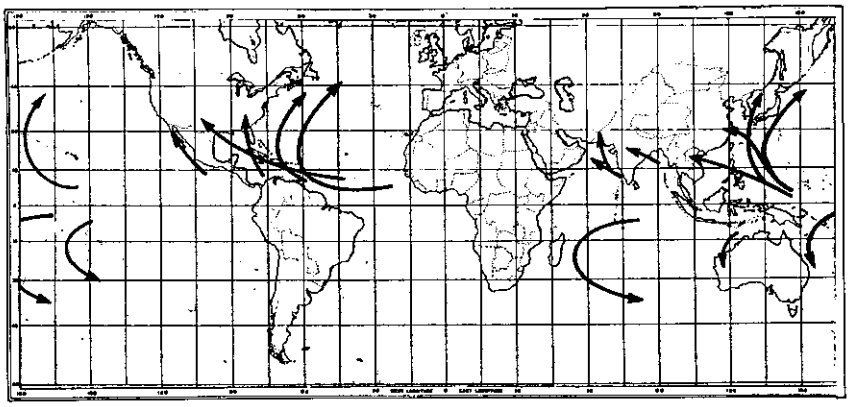

Figure 5. Tropical cyclones.

of weather data available, the reliability of weather communications facilities, the length of the forecast period, and the experience of the forecaster. Other factors being equal, the reliability of forecasts generally decreases as the length of the forecast period increases.

b. Format. Weather forecasts may be presented in coded (numerical), graphical (pictorial), or written (plain language) format. Normally, weather forecasts for use by Army units will be issued in plain language form. Because forecasts are subject to sudden change, they are usually transmitted by electrical means. Abbreviations are used extensively. The abbreviations used in weather messages are contained in AR 320–50 and in the Federal Aviation Agency (FAA) publication, *Contractions.*

c. Sources. Weather forecasts and special studies are provided by agencies of the Air Weather Service of the Air Force. Air Weather Service is found on all Air Force bases and on many Army bases that have Army aviation units. Division and lower units receive weather forecasts from either attached personnel of Air Weather Service or from higher headquarters.

d. Short-Period Forecasts. These forecasts cover a period up to 48 hours in advance of issue, giving detailed values of the weather elements expected to occur during the period and the time of anticipated weather changes. They are sufficiently reliable for use in detailed short-range planning.

e. Medium-Period Forecasts. This class covers a period of 3 to 5 days, and extended-period forecasts cover periods in excess of 5 days. They are less detailed and specific than short-period forecasts. Usually the weather information is expressed in terms of departure from normal conditions and is suitable only for preliminary planning purposes.

f. Severe Weather Forecasts. These provide warnings of weather conditions that will create unusual difficulties. Examples of severe weather include tropical cyclones, thunderstorms, strong and gusty surface winds, heavy precipitation, and extremes of temperature. The Air Weather Service furnishes such warnings when requested by commanders, based upon the needs of their particular unit or installation. The weather conditions that will be critical vary with the type of unit or installation. For example, one unit may require warnings of winds in excess of 15 to 20 knots, but another may not be adversely affected by wind until the speed reaches 35 to 40 knots or more.

34. Weather Intelligence

a. Dissemination. Timeliness is the critical factor in disseminating weather reports and forecasts. Normally they are transmitted by radio or teletype. Weather information is incorporated in such documents as the intelligence estimate, periodic intelligence report, analysis of area of operations, and the intelligence summary.

b. Responsibility of Intelligence Officer. The intelligence officer at corps and lower levels is responsible for determining the weather information requirements and submitting them to

the Air Weather Service personnel. He informs subordinate units of the weather data required by the Air Weather Service and instructs them in the procedure for collecting and forwarding the data. He disseminates the received weather information and coordinates with G3/S3 in the weather training of subordinate units.

c. Requirements. Weather requirements are of two types—those established by the Army and passed to the Air Weather Service for action, and those established by the Air Weather Service and passed to the Army for action. The intelligence officer coordinates all activities directed toward satisfying these requirements. At division and higher levels this coordination is effected through the Air Force Staff Weather Officer, a special staff officer at those echelons. Below division, the intelligence officer requests Air Weather Service support through intelligence channels. Army weather requirements may include climatic information to be used in the planning phase of an entire campaign or operation, weather forecasts, reports of current weather, and weather summaries. Under conditions of nuclear warfare, timely and accurate weather data, particularly that concerning upper air wind speeds and direction, is essential in fallout predictions. Fallout predictions are required both for friendly and enemy employment of nuclear weapons.

d. Requests. Requests for specific weather information received by the intelligence officer are evaluated to determine whether or not the information can be secured by organic agencies before they are forwarded to the Air Weather Service. In all cases, before forwarding the request the intelligence officer insures that requests from various units do not overlap and that they cannot be fulfilled from information already available.

e. Information Sources. Weather data required by the Air Weather Service from Army units may be secured by artillery meteorological sections, Chemical Corps units, Army aviation, and forward combat troops. Artillery meteorological sections are capable of making winds-aloft observations and of determining upper air pressure, temperature, and humidity. In addition, they measure and report data for fallout prediction and use by the Air Weather Service. This information is transmitted every 3 hours. Chemical Corps smoke battalions can furnish information concerning surface winds and temperature. The pilots of Army aircraft are capable of reporting weather conditions within their area of flight operations. Forward combat units can provide weather data obtained by visual observation, and if required, they may be equipped with instruments for obtaining additional weather data.

f. Interpretation. An intelligence officer does not merely disseminate verbatim the weather forecast received from higher headquarters. He must interpret it in relation to particular operations. He also receives interpretations from such special staff officers as the chemical officer (toxic chemical interpretations and interpretations relative to fallout predictions and travel of fallout clouds), the aviation officer, and the Staff Weather Officer. The weather information that he transmits to the command must be presented in its most usable form, with the operational aspects of the data indicated whenever applicable.

35. Effects of Temperature

a. Temperature. Periods of freezing temperatures will increase the trafficability of some soils, while with others it may create ice sheets on roads, making movement more difficult. Thawing temperatures may make frozen soils difficult to traverse and may damage roads with poor foundations. The ability of projectiles to penetrate the earth is decreased by frozen soil, but freezing increases the casualty effect of contact-fuzed shells. Melting snows may cause floods and in mountain areas result in avalanches.

b. Inversions. Temperature inversions create an exception to the normal decrease in temperature that occurs with increases in altitude. In a temperature inversion, the air nearest the ground is colder than the overlying air. The lower air remains stable. Dust and smoke remain near the ground, reducing visibility and air purity. Inversion conditions are favorable to either enemy or friendly employment of toxic chemical or biological agents. Radar beams may also be refracted or ducted due to inversions.

c. Site Selection. In selecting sites to provide protection against low temperatures in the

northern hemisphere, preference should be given to the southwesterly slopes of hills and mountains, where the temperature usually is higher than on other slopes. Cold air flows downslope and remains pocketed in inclosed drainage areas or is dammed by forests or other barriers. These cold air pockets have the lowest temperature of the terrain, and often are characterized by freezing or fog when adjacent areas are frost-free or clear. In areas of frequent calm or near calm conditions such cold air drainage areas should not be selected for troop bivouacs or for such facilities as motor pools and hospitals. In hot climates, caution is required in utilizing cold air pockets, since they are likely areas for the formation of ground fog and excessive humidity. In windy areas, on the other hand, these pockets provide shelter from the chilling effects of the wind. Areas susceptible to cold air drainage can be readily located by ground reconnaissance or from topographic maps by visualizing the flow of cold and dense air over the terrain. In general, concave land surfaces facilitate the accumulation of cold air, and convex surfaces favor drainage of air from the surface. Toxic chemical and biological aerosols also tend to collect in depressions and low places. In areas where heating is required, careful selection of the terrain in locating bivouacs and other installations will save fuel. If temperature data are available for various possible sites, or can be estimated by altitude factors and terrain configuration, fuel requirements may be closely ascertained. Toxic chemical agents vaporize more rapidly in high ambient temperatures than in low ambient temperatures. The effects of weather on toxic chemical and biological agents, and on radiological contamination, are discussed in FM 3–5 and TM 3–240. Temperature has no significant effects upon the intensity of blast or the thermal radiation of nuclear weapons.

36. Winds

a. Description. In arid or semiarid areas, strong winds frequently raise large clouds of dust and sand which greatly reduce observation. Similar effects result in snow-covered regions, where blowing snow may reduce visibility over wide areas. Observation aircraft may be grounded entirely during such periods. The speed and direction of the wind are prime considerations in areas contaminated by toxic chemical agents, biological agents, and radiological fallout. Winds of 5 to 16 kilometers (3 to 10 miles) per hour provide the most favorable conditions for the employment of contaminating agents. Winds below or above that range cause a loss of effectiveness in the use of gas, smoke, chemicals, radioactive clouds, and mists. The direction of the wind must be considered for the protection of friendly troops. In areas characterized by great turbulence and variable winds the use of contaminating agents is highly dangerous.

b. Projectiles. Winds tend to deflect projectiles from their normal paths, particularly when they are fired at long ranges. The effect that wind will have on a projectile increases with an increase in the velocity of the wind and the size of the projectile. To obtain accuracy in artillery fires, the direction and velocity of the wind must be known in order to apply compensating corrections to firing data. Winds also affect the efficiency of sound-ranging equipment.

c. Parachute Landings. Parachute landings are feasible in winds up to 25 kilometers (15 miles) per hour. At higher velocities, the wind tends to scatter troop concentrations, to foul equipment, and increase the number of casualties from landing accidents. Strong winds also increase the time that parachutists must remain in the air, as well as the time required to secure equipment and prepare for combat after landing.

d. Amphibious. Strong winds hinder amphibious operations by creating high seas which will prevent landing craft from landing or retracting.

e. Nuclear. Wind speed and direction have no influence upon the blast or thermal radiation effects of nuclear weapons, nor upon the range of the initial nuclear radiation. Winds at all atmospheric levels are significant factors, however, in determining the location of radiological fallout resulting from the surface, subsurface or airburst of a nuclear weapon. Contaminated dirt and debris carried upon the column and cloud will be deposited downwind.

f. Aerosols. The effectiveness of toxic chemical and biological agent aerosols is influenced

by the direction and speed of the wind. Such aerosols are dissipated rapidly in high winds. The use of toxic chemical agents in vapor form is most effective on clear or partially clear nights when the air usually is most stable.

g. Radar. Strong winds can damage radar antennas or even prevent use of the radar.

37. Effects of Humidity

a. Ballistics. The effects of humidity upon ballistics are important because of the relationship of humidity and density. The amount of water vapor in the air affects the trajectory of projectiles by the influence that it has upon air temperature and density. Humidity also has an effect upon the distance that sounds travel, thus affecting sound-ranging operations. Humidity does not seriously decrease the effectiveness of most toxic agents and may increase the effectiveness of some, such as blister gas. The effectiveness of some biological agent aerosols may tend to be increased by moisture in the air since living organisms are affected adversely by dry air and direct sunlight.

b. Smoke. In the use of a screening smoke, a humidity of 90 percent will have twice the obscuring effect of a humidity of 40 percent. With this increase in relative humidity, only one-fourth of the amount of smoke-producing material need be used.

c. Nuclear. Humidity has no influence upon the blast effect or nuclear radiation of a nuclear weapon and no direct effect upon thermal radiation intensities. It will affect target vulnerability to a degree, because it will determine the moisture content of clothing, structures, equipment, and vegetation and their susceptibility to ignition. This effect is pronounced, however, only when a very high or very low relative humidity has prevailed over a long period.

38. Cloudiness

a. Effects. Daytime cloudiness reduces the amount of heat received from the sun at the earth's surface, slowing down the drying of roads and affecting the trafficability of soils. Extensive night cloudiness prevents the loss of heat from the earth's surface due to radiational cooling and results in higher nighttime temperatures. Cloudiness chiefly affects air operations by limiting aerial observation and reconnaissance. Dense clouds above the camera level may reduce light intensity to the point that photography becomes difficult or impossible. A high, thin layer of clouds, on the other hand, may eliminate ground shadows and thus improve the quality of aerial photographs. In cloudy areas, close combat air support may be prohibited or restricted to aircraft equipped with suitable navigation instruments.

b. Searchlights. Low-lying clouds may be used to advantage by reflecting searchlight beams to illuminate the ground surface. Any considerable degree of night cloudiness reduces the amount of moonlight that reaches the ground. If the fullest utilization of twilight periods is desired, the extent of cloud cover must be considered.

c. Nuclear. Clouds have no influence upon the blast effect of nuclear weapons that are burst below them, nor do they affect nuclear radiation, but they may affect the intensity of thermal radiation reaching a target. If a weapon is burst above or within a continuous cloud layer over the target, a large portion or all of the thermal radiation may be attenuated, with a serious loss of effect. The amount of loss will depend upon the thickness and continuity of the cloud layer and the position of the burst with respect to it. If a weapon is burst below a continuous or nearly continuous cloud layer, some of the thermal energy may be reflected from the cloud layer downward on the target area, enhancing the total thermal effect.

39. Rainfall

a. Amount. When planning extended operations, the average amount of precipitation occurring in the proposed area must be considered. An area with 50 centimeters (20 inches) or less of rainfall in a year normally will not have adequate supplies of water for military purposes. Rainfall of 50 to 200 centimeters (20 to 80 inches) a year presents no serious problems in operations, other than those that occur in rainy seasons through localized flooding and poor soil trafficability. Annual rainfall in excess of 200 centimeters (80 inches) generally hinders normal operations during the seasons that the greater amount of this rainfall occurs. The seasonal and daily cycle of precipitation (fig. 6) affects the scheduling of military activities. Seasonal distribu-

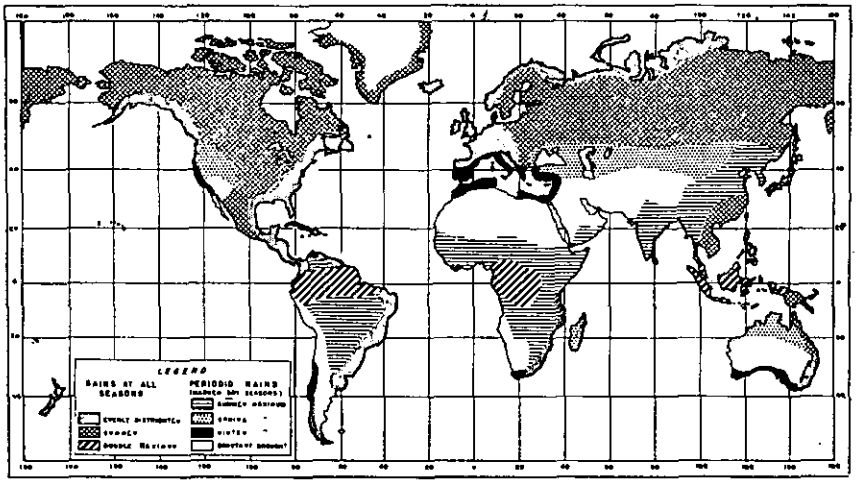

Figure 6. Seasonal distribution of rainfall.

tion may be uniform throughout the year or it may occur in distinct wet and dry periods. In the monsoon areas of southeast Asia, for example, the rains come suddenly and with such violent downpours that some military operations must cease almost entirely, and plans must be revised. During rainy seasons in most tropical or semitropical areas, there usually are predictable periods of maximum rainfall occurring at certain times of the day which must be considered when planning construction work or tactical activities. The maximum rate of precipitation expressed in inches per day or hour may also be critical in designing culverts or other facilities for draining excess water.

b. Trafficability. Precipitation affects soil trafficability and hence cross-country movement. In areas of seasonal precipitation, the cross-country movement characteristics of an area may change drastically each season. Seasonal floods may swell or flood streams, making fording and bridging operations difficult or impossible. Snow and sleet hamper movement on roads in winter, often making them impassable in mountainous areas. The snow that accumulates in mountains during the winter months frequently affords a water supply throughout the year to lower, drier regions.

c. Visibility. Precipitation usually has an adverse effect on visibility and observation, although rain sometimes may wash excessive impurities from the air. Rain and snow aid concealment, and may facilitate surprise attacks. Operation of listening and sound-ranging posts is often limited by precipitation.

d. Neutralization. Rain and snow normally reduce the effectiveness of toxic chemical and biological agents. Heavy or lasting rain washes away these agents and may neutralize them. Snow may cover liquid toxic agents so that little vapor or contamination hazard appears until the snow melts. Heavy precipitation will tend to dilute the concentration of biological agent aerosols.

e. Communication. Precipitation may have an adverse effect upon communications, reducing the range of field wire circuits and producing radar "clutter" which tends to obscure target echoes.

f. Nuclear. Precipitation has a significant influence upon the blast effect of a nuclear weapon, but no effect upon initial nuclear radiation. It affects the range of thermal intensity to the degree that it reduces visibility. Buildings, equipment, debris, vegetation, and other normally flammable elements will require higher thermal intensities for ignition, and the spread of primary or secondary fires will be limited. Residual radiation may be affected. If the radioactive particles formed in an airburst are ingested into rain-bearing clouds, the nuclear cloud (if it does not rise above the rain-bearing clouds) will become so mixed with the rain cloud that it will become an integral part of the rain-producing system. The radio-

active material will be deposited with the rain over a large area. Heavy rain over an area would wash away some of the material from a contaminating burst, either air, surface or subsurface, possibly concentrating it in other areas where there are watercourses, low ground, drainage system, or flat undrained areas.

Section II CLIMATE

40. Definition

a. Elements. Climate (fig. 7) refers to the general variation and pattern of the primary climatic elements which include temperature, precipitation, humidity, winds, and air pressure. It is a composite or generalization of the day-to-day weather at a given place or area over a long period of time. The strength and direction of winds, amount of precipitation, and average temperatures (figs. 8 and 9) that will prevail in an area can be approximated, based upon statistics compiled for previous years. These climatic elements may be described by graphs or charts in terms of means, ranges, average maximums and minimums, extremes, and frequencies of occurrence.

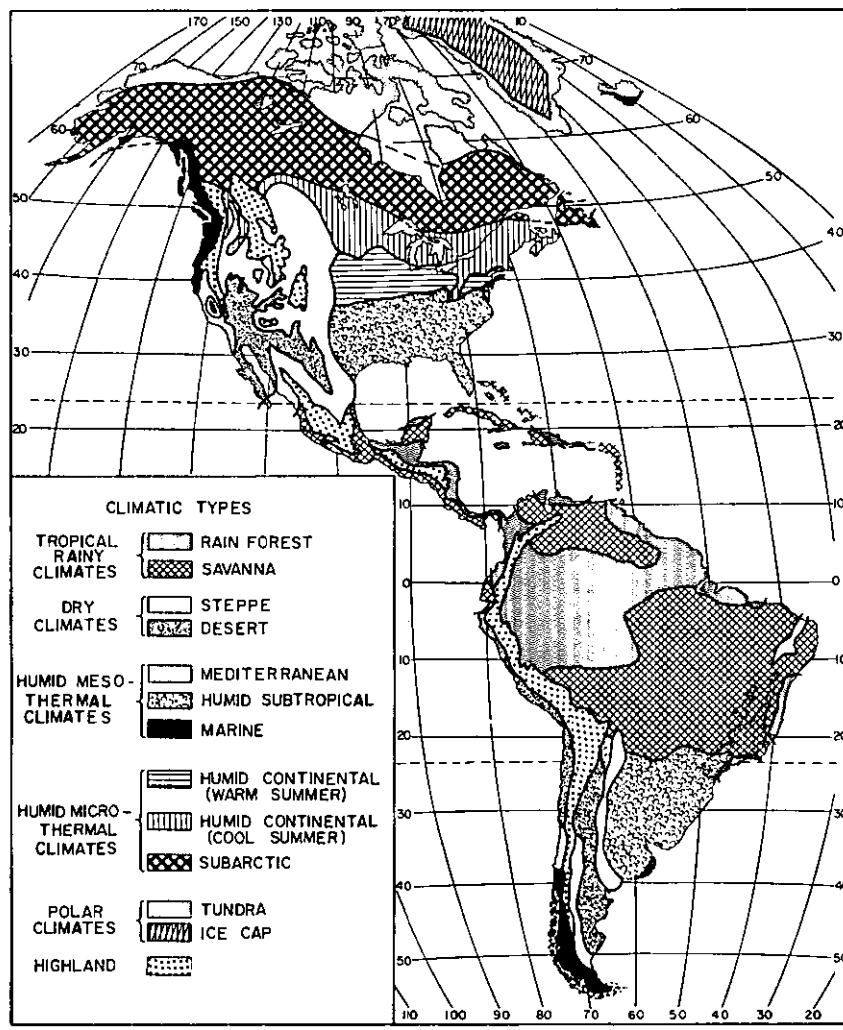

Figure 7. Major climate regions.

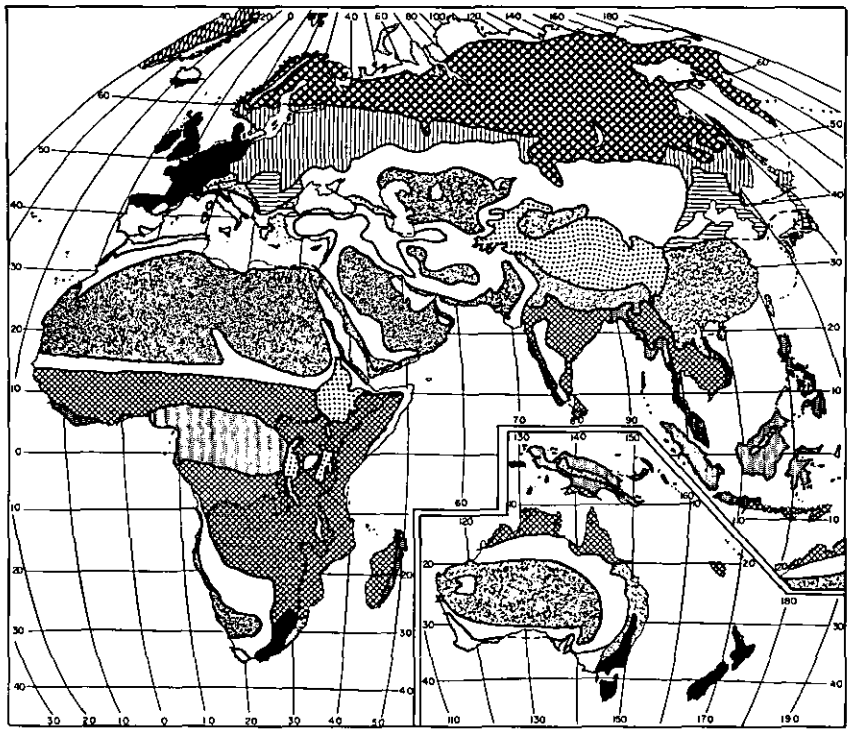

Figure 7—Continued.

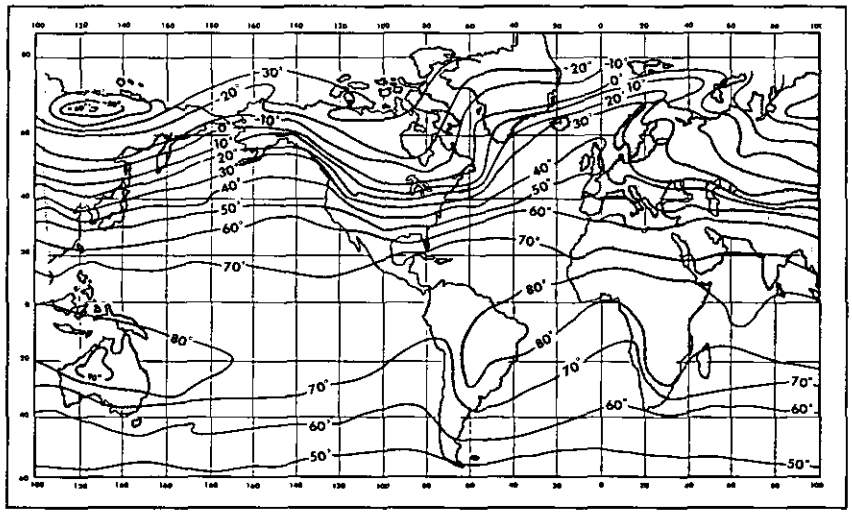

Figure 8. World temperatures in January.

b. Terrain. Although the heat transmitted by the sun to the earth is the dominant factor in weather and climate, terrain has a major effect upon the climate in many regions. High mountains can block the movement of air masses and act as climatic divides. Terrain can also effect differences in climate between land and ocean areas, where the land has higher summer temperatures and lower winter temperatures than the adjacent body of water. Local terrain influences may also be highly significant in military operations. The ground configuration often strongly affects the pattern of occurrence of fog, surface winds, and other

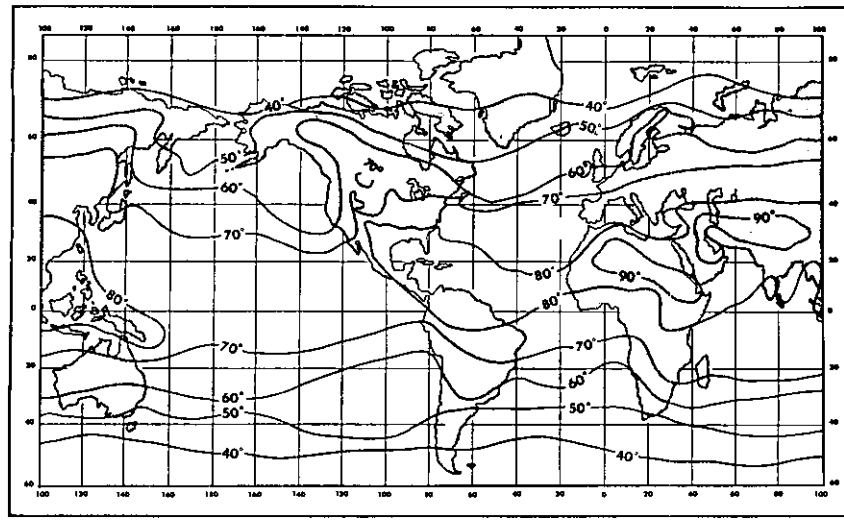

Figure 9. World temperatures in July.

conditions. Information about these local conditions frequently can be obtained only by the analysis of topographic maps, ground reconnaissance, and the interrogation of inhabitants.

c. Plants. The influence of climate on the growth of plants is a predominant factor in their distribution, and the relation between soil formation and climate is so close that the pattern displayed by a soil map will provide an indication of the climatic conditions.

41. Tropical Rainy Climates

a. Rain Forest Climate. The tropical rain forest climate occurs in a belt generally extending from 5° to 8° on either side of the Equator. In some regions, such as the Amazon Basin and the Congo Basin, the air is always hot and damp, there are frequent torrential rains of short duration, and the winds are feeble or absent for long periods of time. This climatic type is also found on windward coasts, where, between latitudes of 5° and 25°, easterly trade winds blow almost constantly over hills or mountains. The cooling of these winds as they rise over the barriers produces an extremely heavy rainfall. This occurs, for example, in portions of Hawaii, the Philippines, the eastern coasts of Central America, Brazil, Madagascar (Malagasy), and most of the islands in the southern Pacific Ocean. In this type of climate, the rays of the sun are nearly vertical most of the time, so that days and nights are practically equal in length throughout the year. Night temperatures usually are a few degrees lower than daytime temperatures. There are no clearly marked seasons. Relative humidity is high at all times, and cloudy weather prevails. There are heavy rains on at least 4 or 5 days each week during the rainiest months, with the greatest amounts during the periods when the sun is most directly overhead. The rains are torrential, often accompanied by thunder and lightning. Ordinarily the rain begins in the afternoon, when the heated air is rising most rapidly, and ends before nightfall, although occasionally a light rain will continue into the night.

b. Savanna Climate. The tropical savanna climate occurs generally in the regions from 5° to 15° on either side of the Equator, between the dry climates and the tropical rain forest regions. Instead of the dense forests typical of the tropical rain forest climate, the savanna regions have more open forests and large areas covered with tall grasses. Savanna regions have high temperatures, with annual ranges (difference between mean temperature of the warmest and coldest months of the year) varying between 5° and 15° F. The total amount of rainfall is less than that of the tropical rain forest climate. There are distinct wet and dry seasons, and usually the rainy season begins and ends with squalls and violent thunderstorms. During the rainy season, periods of intensely hot sunshine also alternate with

brief, violent deluges of rain. The amount of rainfall varies considerably, so that there are years of drought and years of flood. In the dry season the weather resembles that of desert regions, with very little rainfall. Trees lose their leaves, many small streams are dry, and the soil becomes hard and cracked. Visibility is greatly reduced by dust and the smoke from grass fires.

c. Monsoon. In certain parts of southern and southeastern Asia, the climate is greatly influenced by monsoon winds. The wet and dry seasons coincide respectively with the onshore and offshore winds.

42. Dry Climates

a. Description. Dry climates are those in which the evaporation rate exceeds the precipitation rate. The dry climates are located on the leeward interior portions of continents. There are two subdivisions: the arid or desert type, and the semiarid or steppe type. In general, the steppe is a transitional region surrounding the desert and separating it from the humid regions. Dry climates are characterized by extreme seasonal temperatures with large annual ranges. Daily ranges also are high. Humidity is relatively low, averaging from 12 to 30 percent around the middle of the day. Generally the skies are clear and cloudless. Because vegetation is meager, the barren surface of the dry earth becomes very hot during the day and cools rapidly at night. The vegetation offers little friction to the moving air, and accordingly, strong, persistent winds are typical of desert regions.

b. Low-Latitude Desert Climates. These occur in the vicinity of 20° to 25° north or south, with the average positions of their extreme margins at approximately 15° and 30°. The Sahara and Australian Deserts are typical examples of this type of climate. In these desert regions, rainfall is not only small in amount, but erratic and uncertain. However, infrequent heavy showers may turn dry streambeds into raging torrents. Often there is no rainfall for several years, and the skies are almost always clear and cloudless.

c. Low-Latitude Steppes. These are semiarid, having a short period of rain-bearing winds and storms each year. Precipitation, however, is meager and erratic. Steppe regions on the poleward sides of deserts have almost all their annual rainfall in the cool season. Those adjoining savannas on the equatorward sides of deserts generally have a brief period of relatively heavy rains during the time when the sun is highest.

d. Middle-Latitude Dry Climates. These occur within the deep interiors of continents, in the regions surrounded by mountains or plateaus that block the humid maritime air masses. Rainfall is meager and undependable, as in the low-latitude deserts, but there is also a season of severe cold. In winter there may be a small amount of snow, frequently accompanied by strong winds. The temperature and weather characteristics are similar to those of humid continental climates in comparable latitudes, except that there is less rainfall. The area immediately to the east and west of the Caspian Sea is a typical example of this climate.

e. Middle-Latitude Desert Climate. This climate is characterized by lower temperatures and precipitation than low-latitude desert climates. This climate occurs in the basinlike, low-altitude areas, surrounded by high-land rims, that exist in some continental interiors. The Great Basin of the U.S. and the Turkestan Basin of Asia have this type of climate. Summer temperatures are high. Middle-latitude steppes occupy intermediate locations between deserts and humid climates. They have small amounts of rainfall, which is usually unpredictable in amount or time of occurrence.

43. Humid Mesothermal Climates

a. Description. These climates are characterized by moderate temperatures that occur in a seasonal rhythm. They are divided into three general categories—Mediterranean climate, humid subtropical climate and marine west coast climate.

b. Mediterranean Climate. This climate has hot, dry summers and mild winters, during which most of the annual precipitation occurs. Annual rainfall usually ranges from 38 to 64 centimeters (15 to 25 inches). In the winter months, the average temperature is usually between 40° and 50°F.; in the summer, it ranges generally from 70° to 80° F. This type

of climate occurs in five regions—the borderlands of the Mediterranean Sea, central and coastal Southern California, central Chile, the southern tip of South Africa, and parts of southern Australia. Coastal areas often have a modified type of Mediterranean climate, with cool summers accentuated in some areas by the cool ocean currents offshore. There is apt to be a cool daily breeze along the seacoast and for a short distance inland. Relative humidity is high. Fogs are frequent, but usually are dissipated by the heat of the sun in the early morning hours. Winters are mild and frost infrequent, and the annual change in temperature at some locations is uncommonly small. Summer days in Mediterranean climates are warm to hot, with bright sunshine, low relative humidity, and nearly cloudless skies. Daily weather becomes erratic and unpredictable in autumn. The winds are less regular and there is occasional rain. Temperatures remain relatively high. Winters are mild and warm, with occasional frosts and relatively abundant rainfall.

c. Humid Subtropical Climate. This climate occurs in regions located on the eastern sides of continents, generally from about latitude 25° poleward (north or south) to 35° or 40°. This type of climate is found, for example, in the American Gulf States. Temperatures are similar to those of the Mediterranean climate, with less contrast between regions on the coast and those located inland. Rainfall ranges from 75 to 165 centimeters (30 to 65 inches) a year at most locations. In the summer, humidity is high, temperatures average from about 75° to 80°F. in the hottest month, and there are frequent thundershowers. Nights are hot and sultry. There is no drought season, but normally there is less rain in winter than in summer. Severe tropical cyclones occur most frequently in the late summer and early fall. Winters are relatively mild in this type climate. Temperatures in the cool months usually average between 40° and 55°F. with the midday temperature around 55° to 60°F. and the night temperature from 35° to 45°F. The high humidity, however, makes the nights chilly and uncomfortable. Snow may fall occasionally, but it does not remain for more than 2 or 3 days. Daytime temperatures may be raised above 60° or 70°F. by the arrival of a tropical air mass, then be reduced by a subsequent polar wind as much as 30° F. in 24 hours, resulting in a severe freeze.

d. Marine West Coast Climate. This climate occurs on the western or windward sides of continents, poleward from about 40° latitude, and results from onshore westerly winds that blow over the land from adjoining oceans. It borders the Mediterranean type on its equatorward margins, extends into the higher middle latitudes and ends at the subarctic or tundra climate. Where mountains are closely parallel to the west coast, as in Scandinavia, this type of climate is confined to a relatively narrow region on seaward side of the highlands. In parts of western Europe, where there are extensive lowlands, the effects of the ocean conditions have an influence on the climate for many miles inland. Summers are cool with occasional hot days but no severe or prolonged heat waves. Rainfall is fairly abundant. Winters are mild, particularly in western Europe, where a great mass of warm water known as the North Atlantic Drift lies offshore. Cloudy skies and a humid atmosphere are prevalent. There are frequent severe frosts. The midday temperatures of most winter days are relatively high. During unusually cold periods, temperatures may remain below freezing for several days. The winter season is marked by severe storms, fogs, and mist. Where the western coasts are bordered by mountain ranges, as in Norway and Chile, precipitation may reach a total of 250 to 380 centimeters (100 to 150 inches) a year. In areas consisting predominantly of lowlands, rainfall usually averages from 50 to 90 centimeters (20 to 35 inches) a year and may fall steadily for several days at a time. In mountainous regions, such as the Cascade Range or the Scandinavian Highlands, snowfall is very heavy. The marine west coast climate is cloudy, and has mist or fog for at least 40 days a year at many locations.

44. Humid Microthermal Climates

a. Types. The humid microthermal climate occurs in the Northern Hemisphere northward from the subtropical climatic regions and in leeward interior locations. Latitudinal spread is from about 40° N to 60° or 65° N. It has colder winters than the mesothermal type, with larger annual changes of temperature,

longer frost seasons and snow cover that lasts for considerable periods. Humid continental and subarctic are the principal types of microthermal climate.

b. Humid Continental Climates. These climates border the marine west coast climatic regions. Where there are mountain barriers, as in North America, the change between the two types of climate is abrupt, but it is very gradual where there are no barriers, as in the lowlands of western Europe. Seasonal differences are extreme, with very cold winters and warm to hot summers. Along the seaboard, the summer heat is oppressive and sultry because of the higher humidity, and the winter cold is more raw and penetrating than in the drier interior regions. Along the interior margins, humid continental climates border upon the dry climates and have subhumid characteristics. The prairies of North America and interior Eurasia are examples of such climatic regions. In these areas, the maximum rainfall usually occurs in late spring and early summer, rather than at the time of greatest heat. In winter, regions with a humid continental type of climate normally have a permanent snow cover that lasts from a few weeks to several months. Summer rains usually occur in sharp showers accompanied by thunder and lightning. Winter in the prairie regions is characterized by frequent changes in weather conditions, with occasional blizzards, known as burans. A blizzard is marked by violent gales, drifting snow, and extreme cold. Although there may be no precipitation falling, the air is filled to a height of several hundred feet by swirling masses of dry, finely pulverized snow. Afternoon thunderstorms frequently occur during summer in prairie regions.

c. Southern Margins. Regions on the southern margins of microthermal climates have long, hot, and humid summers lasting from 150 to 200 days between the periods of frost. Winters are cold, with frequent intervals of mild, rainy weather.

d. Winter. Winter is the dominant season on the poleward side of regions with this type of climate. Summers are relatively short, usually comprising a period of about 5 months. Temperature changes of as much as 40° F. in 24 hours are common in spring and autumn.

e. Subarctic Climate. This climate occurs in latitudes of 50° to 60° in the Northern Hemisphere. The Eurasian region extends from Finland and Sweden to the Pacific coast of Siberia, and in North America, the subarctic stretches from Alaska to Labrador and Newfoundland. Long, extremely cold winters and very brief summers characterize this type of climate. Winter quickly follows summer, with only a short period of autumn intervening. A large part of these regions are frozen to a considerable depth, with only a few feet of the upper part thawing out in the summer. There is little precipitation in subarctic regions. No more than 40 centimeters (15 inches) a year falls over the greater part of the Siberian area. In most of subarctic Canada the precipitation is less than 50 centimeters (20 inches) annually. Precipitation exceeds 50 centimeters (20 inches) chiefly along the oceanic margins of Eurasia and North America.

45. Polar Climates

a. Location. The poleward limit of forest growth usually is considered the dividing line between polar climates and those of intermediate latitudes coinciding with a line (isotherm) connecting points having a temperature of 50°F. for the warmest month. A mean annual temperature of 32°F. or below is also a distinguishing feature of polar climates. In the Southern Hemisphere, the only large land area with a polar climate is the Antarctic continent. In the Northern Hemisphere, this climatic region includes the Arctic Sea, the borderlands of Eurasia and North America, with the island groups that are north of these continents, and ice-covered Greenland. The Arctic is almost a landlocked sea and the Antarctic is a seagirt land with important climatic differences between them. The climate has fewer wide variations in the Antarctic because it is a single land mass surrounded by oceans with a uniform temperature.

b. Temperature. Polar climates have the lowest mean annual and summer temperatures and although the sun remains above the horizon for 6 months of the year, the rays are too oblique to raise the temperature significantly. Much of the energy from the sun is reflected by snow and ice, and is consumed in melting the snow cover and evaporating the

water. As a result neither the land surface nor the air adjacent to it becomes warm.

c. Precipitation. Precipitation averages less than 25 centimeters (10 inches) a year over large parts of the polar land areas. Because of the low evaporation and small amount of melting, permanent ice fields several thousand feet thick have accumulated on Greenland and the Antarctic continent.

46. Tundra and Icecap

a. Tundra. Polar climates usually are divided into two types—icecap and tundra. Icecap climates are those where the average temperature of all months is below 32° F., vegetation will not grow, and a permanent snow-and-ice cover prevails (figs. 10 and 11). When one or more months in the warm season have an average temperature above 32°F. but below 50°F., the ground is free from snow for a short period and low sparse vegetation is possible. This climate is designated as tundra. It is less rigorous than that of the icecap regions. The warmest month isotherms of 50°F. on the equatorward side and 32°F. on the poleward side are considered to be the boundaries. Over land areas, tundra climate is confined largely to the Northern Hemisphere. Ocean prevails in those Antarctic areas where the tundra climate normally would be found. Summers warm enough to develop a tundra climate occur only in the most northerly fringes of the Antarctic and on certain small islands of the region. The most extensive tundra areas are on the Arctic Sea margins of Eurasia and North America. Long, cold winters and brief, cool summers characterize the tundra climate.

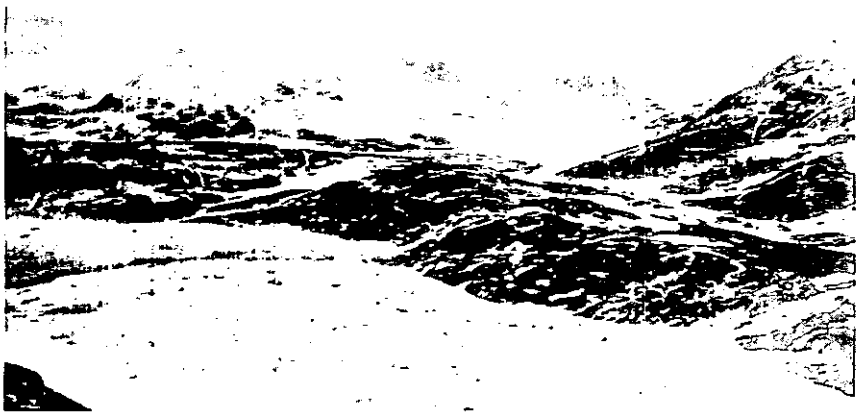

Figure 10. Arctic terrain.

b. Temperatures. Average temperatures usually are above freezing only for from 2 to 4 months of the year, and killing frosts may occur at any time. Fog is prevalent along the coast, frequently lasting for days at a time. Snow cover disappears for 1 or 2 months during the summer season, and the lakes usually are free from ice. Drainage is poor because of the permafrost, resulting in many bogs and swamps. Summer temperatures do not differ greatly in the various tundra regions. There is, however, a considerable variation in winter temperatures. Average temperatures in the Arctic coastal areas of Siberia average about −35° to −40°F. in January and February, with even lower temperatures inland. Along the Arctic borders of North America, the temperature for comparable periods is higher, and winters are less severe.

c. Precipitation. Annual precipitation normally does not exceed 25 cm to 30 cm (10–12 inches) in the tundra regions, although larger amounts are received in parts of eastern Canada, particularly in Labrador. Usually the most precipitation occurs in summer and autumn, the warmest seasons. Most of it is in the form of rain, with occasional snow. The winter snow is dry and powdery, forming a compact cover.

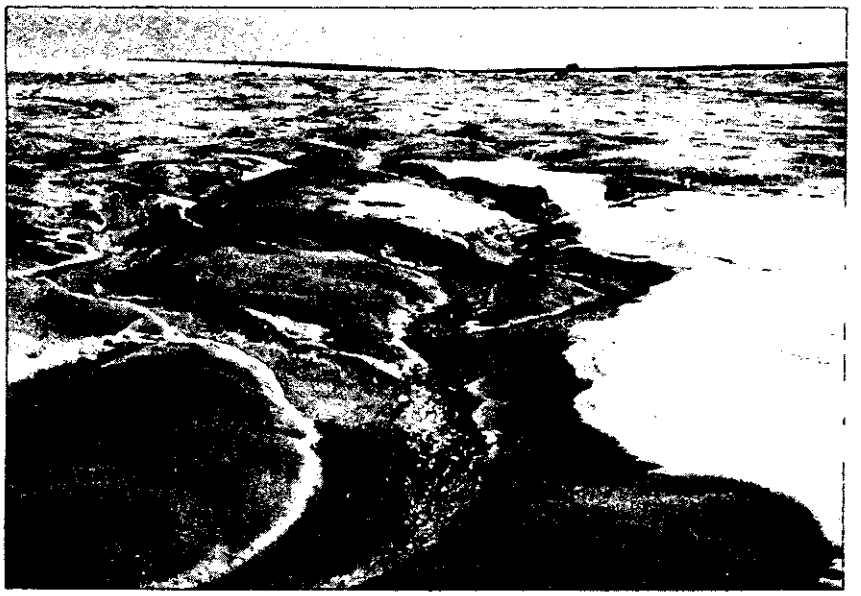

Figure 11. Arctic tundra, showing warm-weather drainage.

Often it is accompanied by strong blizzard winds which pile up the snow on the lee sides of hills and in depressions, sweeping exposed surfaces bare. There is no vegetation to break the force of the wind and to hold the snow cover.

d. Icecap. This climate characterizes the permanent continental ice sheets of Greenland and Antarctica and the ocean in the vicinity of the North Pole. The average winter-month temperatures range from −35° to −45°F. Storms or violent winds do not occur as frequently in the inner portions of the icecaps as in other climatic regions, but in some marginal areas there are extreme gales caused by the precipitous descent of cold air from the continental ice plateau.

47. Climatic Studies

a. Records. Climatic studies are based upon the records of past weather in a given area compiled over a long period of time. They are used in preliminary planning to provide an estimate of the climatic averages that may be expected during the period of the proposed operations. These studies are of particular value in developing new equipment and in anticipating logistical problems. Special climatic studies may be prepared covering winds, rainfall, tides, sea conditions, state of ground, and similar aspects of a specified area. Such studies have been made, for example, to provide data for use in determining—

(1) Location of camps, training areas, depots, and landing fields.
(2) Coastal areas most suitable for amphibious operations.
(3) Operations of aircraft over certain mountainous areas.
(4) Smoke behavior in specified localities.
(5) Seasonal fuel requirements by weight, quantity, and type.

b. Requests. Requests for climatic studies should be made as far in advance as possible, and should provide all pertinent information, including mission, area and time, operational limits, flexibility permitted, and the form of presentation.

Section III. OPERATIONS IN EXTREME CLIMATES

48. Desert Regions

a. Weather. High summer temperatures are normal in desert areas; the summer maximum may reach 120° to 130°F. During daylight hours the thermal action may be so violent that planes cannot operate safely at lower alti-

tudes. The variation between day and night temperatures is great, the temperature often dropping below the freezing point in winter. These sudden changes in temperature occasionally give rise to winds of hurricane force that carry large quantities of dust and sand. Under these conditions, visibility is very poor and movement may be impossible. Climatic conditions in desert areas also increase maintenance requirements of mechanized units. Rain is infrequent in desert regions, usually averaging less than 25 centimeters (10 inches) a year, but it may come in sudden downpours. Water sources are few, and frequently are polluted and brackish. Usually water for military forces must be transported by tank truck, rail, or pipeline from sources outside the desert area. Winds blow almost constantly in the desert, frequently limiting the use of smoke and other chemical weapons. Minefields may be made useless by the blowing dust and sand. The wind either blows away the sand, exposing the mines, or deposits large quantities of it on the minefield, preventing detonation of the mines. In heavy dust and sandstorms, the operations of mechanized units are similar to those conducted at night.

b. Natural Features. There are few landmarks in a sandy desert region. The most prominent features are the huge dunes created by sandstorms (fig. 12). Usually the surface of a sand dune is packed firmly by the wind for a depth of about 5 centimeters (2 inches). This surface will support considerable weight, but detours may be necessary because many of the dunes are high, with steep slopes. Areas of loose sand impede movement on foot or by wheeled vehicles, but tracked vehicles are able to operate in shallow sand. In flat, hard-surfaced areas, roads and trails are not necessary and all types of vehicles can move cross-country. Salt marshes, dry lakes, and wadis (dry streambeds) occur along coastal areas or inland in depressions. Wadis and dry lakes are impassable when wet and contain a powdery silt when they are dry which may cause vehicles to bog down.

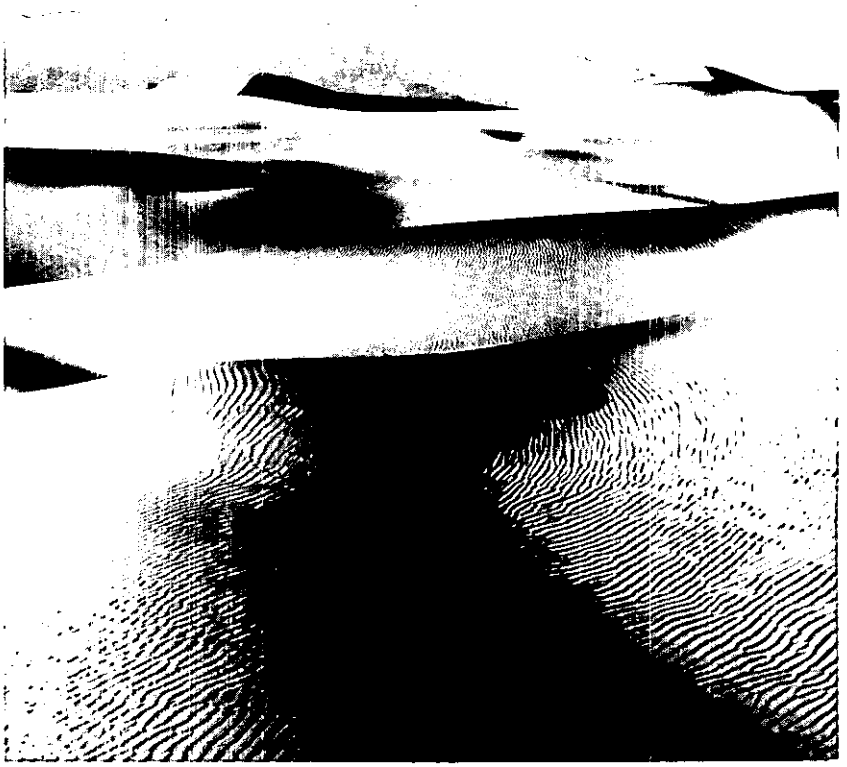

Figure 12. Sand dunes (Death Valley, California).

c. Manmade Features. Well-defined roads are scarce in desert regions, although there usually are trails between water sources. Occasionally flash floods may cut the routes for short periods of time. Dust and sand storms may prevent traffic through lack of visibility and maintenance difficulties. A surfaced main supply route is essential and usually must be constructed. Road location is difficult and time-consuming, requiring extensive map study and area reconnaissance. Buildings must be strong enough to withstand the frequent high winds and constructed tightly to reduce the infiltration of blowing sand and dust. Field fortifications in sand require adequate strengthening, with a maximum use of sandbags. In rocky deserts, field works can be installed only with great difficulty. Field fortifications are easy to dig in sandy deserts, but they must be revetted, and may be filled quickly with drifting sand.

d. Military Aspects.

(1) *Key terrain features.* In desert operations, terrain features usually are not major objectives, since the possession of a particular piece of ground seldom contributes materially to the destruction of the enemy force. Oases and other water sources are always critical, however, because an adequate water supply is a fundamental requirement of military operations in arid or semiarid regions.

(2) *Observation and fields of fire.* The brilliant sunlight of desert areas reflected from the light colored ground surface creates a glare. An observer with the sun to his back may see well, but the glare greatly reduces visibility when he faces toward the sun. He loses his depth perception and will confuse objects which are in shadows or haze. On hot days, a shimmering haze may nullify ground observation at ranges of 450 meters (500 yards) or less, depending on local conditions. An optical phenomenon encountered in desert regions is the mirage, an effect produced by layers of air of varying density across which the observer sees reflections, usually inverted, of some distant object or objects. These occur frequently in summer and are evident in a wide arc which increases as the sun becomes higher in the sky. The effect of a mirage generally is the distortion of objects, particularly in the vertical dimension. This has an adverse effect upon observation, making it particularly difficult to identify vehicles. Distances in deserts are underestimated. Shadows on the light-colored terrain can be seen for miles but tend to distort distant objects. Moonlight in desert areas is much brighter than in other regions and nights usually are very clear, with the haze and glare eliminated. Observation at night may be better than during some periods of the day. In open terrain, sound- and flash-ranging are particularly effective. Artillery observers, however, may find few positions that will allow a commanding view of the terrain. The ability of a weapon to fire effectively in the desert usually is limited only by the range of the weapon and the ability of the observer to adjust fire. There is little vegetation or relief to mask weapons.

(3) *Cover and concealment.* Cover from enemy fire may be afforded by sand dunes, hills, and other irregularities in the desert terrain. Concealment is hard to obtain, since the vegetation is sparse. Camouflage is used more extensively in desert areas than in normal terrain, and reliance must be placed upon artificial means. Camouflage from air or ground observation is extremely difficult to achieve. The movement of troops during daylight is greatly restricted due to the lack of concealment and cover from air attack and troops must be widely dispersed.

(4) *Obstacles.* There are relatively few major obstacles to movement in most desert regions. Although the road net is limited, cross-country movement may be good, varying with the type of surface materials.

(5) *Nuclear weapons.* The ease of dispersion in desert areas avoids a concen-

tration of troops that could provide a profitable target for nuclear weapons. Suitable targets are provided, however, by airfields, communication centers, and supply installations.

(6) *Toxic chemical and biological agents.* Two characteristics of desert regions which limit the employment of toxic chemical agents are the sparseness of vegetation and the extreme variations in ambient temperature. Toxic agents present storage problems because of the wide temperature ranges and the extreme conditions existing during the day. Effective use of toxic chemical agents usually is limited to night. The direct sunlight and dry air which characterize desert regions may present unfavorable environmental conditions for some biological agent aerosols.

(7) *Screening smokes.* Under desert conditions when the winds are still, large-area smoke screening is of considerable importance because of the normal lack of adequate natural concealment and cover.

49. Tropical Regions

a. Weather. Excessive heat and humidity except in tropical deserts characterize tropical regions throughout the year. In the rain forest type of climate, there is little seasonal variation in temperature. The weather is marked by sudden changes, with torrential rains that end abruptly to be followed at once by bright sunshine. Humidity tends to remain high because the vegetation checks evaporation. Although monsoon areas have a dry season, the total rainfall is so great that rain forest vegetation is dominant. High temperatures prevail in the tropical savanna regions, which have distinct wet and dry seasons; but in most of these areas, grass is the predominate vegetation. Both rainfall and relative humidity are high in the wet season, and rainfall is rare and relative humidity ranges from low to high.

b. Natural Features. Military operations in tropical regions are influenced chiefly by the rain forest vegetation. In some areas, such as the Amazon Basin of South America, and in central and west Africa, the rain forest consists of several stories of trees, the foliage of which forms a dense canopy, preventing sunlight from reaching the forest floor, and thus precluding dense undergrowth. In other areas, such as in Southeast Asia and some islands in the Pacific Ocean, where a monsoon climate prevails, the rain forest has a canopy only partly continuous and a dense undergrowth. Rain forest is commonly called "jungle," but the term "jungle" is not recognized as a vegetation type. Terrain covered by the rain forest varies from mountain ranges to low, swampy plains. In Southeast Asia, the Pacific Islands, and parts of Latin America, the rain forest covers irregular terrain. Other rain forest areas, such as those in central Africa and South America, generally are low and level. Some coastal portions of rain forest areas are characterized by mangrove swamps or by open beaches lined with bamboo or coconut groves. Beyond the shoreline there may be paddy fields or pineapple, coconut, sugar cane, or rubber planations. Between these and the rain forest there may be low-lying foothills covered with brush or tall grass. Streams are numerous in rain forest areas, but they are generally muddy and subject to sudden floods. In wet seasons an entire area of flat rain forest may become a continuous swamp. In mountainous areas streams that normally are shallow become torrential shortly after a heavy rain. The characteristics of rain forest terrain and its effects upon military operations are discussed in FM 31–30.

c. Manmade Features. There are few roads or trails in rain forest areas. Usually roads must be constructed, and the use of these is limited to light trucks or light tracked vehicles. Except for coral in some coastal areas, there is a lack of materials suitable for road construction. The dense vegetation, unstable soils, and poor drainage make roadbuilding difficult. To establish and maintain a road net of even minimum standards calls for greater engineer effort than in other types of terrain. Navigable waterways often provide the most efficient routes of communication, although they are highly vulnerable to ambush. Bridges suitable for military loads rarely exist in jungle regions. The construction of bridges is complicated by the frequency and intensity of flash floods, the tendency of some jungle

streams to shift their courses, and the rapid decay of wooden structural members. Engineers must be prepared to repair or replace bridges rapidly at short notice. Aerial trams are useful because of the deep cuts made by jungle streams in hilly or mountainous terrain. Towns and villages in jungle regions rarely provide suitable facilities for military installations. Usually settlements are avoided for hygienic reasons. Excellent anchorages may be found along many tropical coasts, but there are very few water terminals sufficiently developed to be of any value in military operations.

d. Key Terrain Features. In jungle areas, the key terrain features generally are those that provide control of trails, navigable waterways, and beaches suitable for amphibious landings. Possession of the edges of an area of high rain forest could provide observation points, thus giving advantages similar to those derived from the possession of high ground.

e. Observation and Fields of Fire.

(1) *Observation.* In rain forest, the dense vegetation often limits observation to short distances. Usually the canopy in a primary rain forest, which consists of a virgin growth of mature trees, is so thick that it cuts off most sunlight, and visibility is limited to about 20 or 30 meters (20 or 30 yards). Visibility may be limited about 5 meters (5 yards) or less in the secondary forest, which is composed of a second growth that develops when the original forest has been burned off or cut. Rain, clouds, and the steamy exhalation from wet areas also tend to reduce visibility. Because of the limited visibility and the lack of conspicuous landmarks, it is often difficult to locate a ground position from a map. Camouflage from close ground observation is of the greatest importance in the rain forest. In most areas, however, there is less need for artificial camouflage against air observation. Whenever possible, the natural overhead is preserved, since any break in the normally uniform tree canopy is readily noticeable from the air. Because observation is limited, tactical units must employ narrow frontages, reduced distances and intervals between elements, increased patrol activity, and a larger number of liaison parties than required in more open terrain. The difficulties of observation greatly restrict the employment of supporting arms and weapons. Artillery forward observer teams on the ground usually cannot see the burst and must adjust fire by sound spotting and sound sensing methods. Aerial forward observers may be utilized with a higher degree of reliability. Data based on maps or photomaps can be used only to a limited extent.

(2) *Fields of fire.* Since natural fields of fire generally are limited to about 5 or 10 meters (5 or 10 yards), lanes must be cleared. Where the undergrowth is heavy, several days of labor will be required to clear 90-meter (100-yard) fire lanes around a position. In order to avoid revealing weapon positions, a fire lane in dense vegetation usually is in the form of a tunnel from 1 to 3.5 meters (1 to 4 yards) wide, with the overhanging foliage left intact. In rain forest, the most effective weapons are those that can be supplied easily with ammunition and are readily transportable over difficult terrain. Suitable weapons include mortars, machineguns, automatic rifles, and grenades. Armored vehicles cannot move through rain forest unless routes have been prepared. Usually the movement of tanks is limited to beaches, coconut groves, clearings, and improved trails. The principal value of tanks is in the use of their flamethrowers, direct fire weapons, and crushing weight in the destruction of enemy field fortifications. Tanks are highly vulnerable to ambush and close in attack in rain forest terrain. Because the heavy vegetation reduces the ef-

fective bursting radius of artillery shells, weapons of 105-mm or higher calibers must be employed to blast away jungle undergrowth and destroy enemy positions. Artillery pieces should be capable of high-angle fire and should be drawn by tractors or transported by helicopters. Engineer equipment must be available for the improvement of trails, construction of firing positions, and clearing of fields of fire. In some mountainous areas, only pack artillery may be practicable. Air forces are effective in close tactical support of ground elements, but their utility for tactical bombing is less than in other types of terrain. Armed helicopters are used extensively in close support of ground forces.

f. Cover and Concealment. Rain forest provides concealment from air and ground observation and may furnish some cover from small arms fire. The amount of cover given by slit trenches and other field fortifications is often limited by the high water table, which prevents excavating more than a few feet below the surface of the ground.

g. Avenues of Approach. Cross-country movement in rain forest is slow and difficult. Troops may have to cut their way through continuous thick undergrowth or make lengthy detours to avoid impassable swamps. On most trails, troops must move in a column of files, and the average rate of movement rarely exceeds 1.5 km per hour. Usually foot movement may be made most easily on ridges, where the vegetation is more open and the better drainage results in less muddy surfaces. Except for small, fast streams with traversable beds, movement is poorest along the banks of rivers, because of the dense vegetation, mud, swamps, and tributary streams. Even in comparatively dry weather, mud slows down vehicular traffic in the jungles. It may be necessary to supplement motorized transport by the use of helicopters and carrying parties. Jungle roads and trails rapidly disappear unless they are in constant use. Accordingly, maps showing these features seldom are reliable. Air photographs of jungle terrain rarely reveal more than the treetops.

h. Communications. Visual signaling is seldom effective in the rain forest because of the dense growth. The use of messengers is slow and may be hazardous. Wire circuits are hard to install and maintain. The range of radio sets may be greatly reduced by the vegetation, resulting in ranges from 40 to 70 percent less than those considered normal in open or lightly wooded terrain.

i. Toxic Chemical and Biological Agents. Both the weather and terrain conditions in rain forest areas are favorable for the employment of chemical and biological agents. Where the overhead canopy is very dense, however, sprays from aircraft usually are only moderately effective against personnel. The large-scale use of defoliants will increase the fields of fire of weapons, and provide increased observation.

50. Arctic and Subartic Regions

a. Weather. Severe changes in weather are common in arctic and subarctic regions. These changes include shifting periods of severe frosts, mild weather, sudden freezing, snowstorms, strong winds, and dense fogs. Reliable and timely weather forecasts are essential to guard against damage to equipment and installations and to gain any tactical advantages that may be possible by exploiting changes in weather conditions. Arctic operations frequently are hindered by strong winds, which usually occur more often along the coast than in the interior. Wind speeds in excess of 128 kilometers (80 miles) per hour have been recorded at coastal stations. Winds blow continually, and in most areas there are no hills, mountains, or other natural barriers to provide protection. Blowing snow constitutes a serios hazard to flying operations. Winds of 16 to 24 kilometers (10 to 15 miles) per hour will raise the snow several feet off the ground, obscuring such surface objects as rocks and runway markers. The short days and long nights of winter reduce the amount of daylight available for tactical operations and work activities. Nights often are bright because of the illumination of the moon, stars, aurora borealis, and reflections from the snow, so that night movements are possible. The short summer nights permit military operations through the 24-hour period.

b. Natural Features. Following a heavy snowfall, landmarks and other objects become covered, making orientation difficult. Gullies and ditches are filled and obscured so that movement is made more hazardous. The freezing of swamps and lakes may convert obstacles into avenues of approach for the enemy. Warmer temperatures in spring will create thaws and mud in the subarctic, causing rivers and streams to overflow. In mountainous or hilly country, landslides can be expected in the spring, as the result of boulders and smaller rock formations expanding from the warmth of the thawing temperatures.

c. Manmade Features. In the subarctic, routes of communication and transportation are affected by every heavy snowfall and traffic may come to a halt. Strong winds cause snowdrifts requiring a constant clearing of routes, and transportation is slowed greatly by ice and sleet. To avoid these drifts, roads may be routed through woods, where drifts seldom occur, or along the crest of high ground where the snow usually is less deep. In extremely cold temperatures, railroad operation is restricted. Blocked tracks and derailments are frequent; switches often are frozen; snow and rock slides, washouts, and frost heaving damage the lines; and the ice caused by water seepage must be cleared from tunnels before they can be used. Excavation is difficult in either frozen or thawed ground. In frozen ground, handtools are ineffective. Explosives are effective, but they must be employed in quantities greater than required in other terrain. Gravel is easier to excavate than soil, because it has better drainage and accordingly does not freeze as solidly. Foxholes, trenches, breastworks, and emplacements may be provided by digging into the snow or through it into the underlying ground. Snow trenches usually need revetting. In very deep snow, tunnels may be dug to provide concealment. They furnish cover from small arms fire, but do not give protection from artillery fires. The spring thaws in subarctic climates must be considered when planning structures and fortifications. Bunkers, trenches, and other field fortifications must be designed and sited so as to insure good drainage. In the thawing period, roads in low-lying areas and bridges are apt to be washed out. Floating ice will destroy or damage bridges of temporary construction. Runways and landing strips will require considerable maintenance. Airfields that have been improperly designed and constructed may become wholly inoperative for extended periods.

d. Observation and Fields of Fire.

(1) *Observation.* Arctic air is exceptionally transparent, providing visibility over long distances. There is a lack of contrast between objects, however, particularly when they are covered by a layer of new snow. Observation in the Arctic is restricted chiefly by fog, blowing snow, and local smoke. The latter is a serious problem only in the vicinity of larger settlements, where it often accompanies the shallow radiation fogs of winter. A radiation fog results from the radiational cooling of air near the surface of the ground on calm, clear nights. Depth perception is adversely affected by arctic conditions, principally by the extremely clear, dry air, the lack of color differences, and the diffusing effect of light on the crystalline surface of the snow and ice. A hazardous phenomenon that reduces visibility to near zero is the whiteout. When this condition exists, the horizon, shadows, and clouds are not discernible, and only very dark objects can be seen. The amount of light reflected from a snowcovered surface is much greater than that reflected from a darker surface, and accordingly the sun provides greater illumination in the Arctic than in other regions. When the sun is shining, sufficient light is reflected from the snow almost to eliminate shadows except in polar areas where the shadows are quite long when the sun is shining. This causes a lack of contrast, making it difficult for the observer to distinguish the outlines of objects even at short distances. The landscape may appear as a featureless grayish-white field. Dark mountains in the distance may be recognized but a crevasse immediately in front of a mountain may be undetected because of the absence

of contrast. There is good illumination from a full moon, and even the stars create considerable illumination. Only during periods of heavy overcast does the arctic night approach the darkness of other regions. A fog condition peculiar to the arctic climate is ice fog. This is composed of minute ice crystals instead of the water droplets of ordinary fog. Ice fog forms in very cold, still air in a shallow layer next to the ground. It is almost always present at temperatures of −45°F to −50°F in the vicinity of a source of water vapor and remains as long as these conditions persist. Where the smoke from building chimneys contributes water vapor to cold, still air, ice fog may form at temperatures as high as −20°F. When the temperature increases rather than decreases with height through a layer of air, it is termed an inversion. The strong temperature inversions present over the Arctic during winter cause several phenomena that affect observation. Sound tends to carry great distances. Light rays are bent as they pass through the inversion at low angles, often causing objects beyond the horizon to appear above it. This effect, termed looming, is a form of mirage.

(2) *Fields of fire.* The fields of fire of automatic weapons are subject to the effects of wind and snow and the final protective line fires may be rendered ineffective by snow drifts. Impact bursts of high trajectory light artillery, mortar, and hand grenade fires are rendered relatively ineffective by the cushioning effect of deep snow; heavy artillery, however, remains highly effective. The employment of proximity or mechanically timed air bursts and overhead fire usually is advisable. Because of the lack of identifying objects and landmarks on snow-covered terrain, the adjustment of fire is difficult. Registration fire with air observation and by sound and flash is hampered, since the snow obscures projectiles and bursts. A round bursting on impact in deep snow appears as a small white splash, making sensing extremely difficult. Because of the cushioning effects of the snow, mines may fail to detonate. The clear air and snow cover may increase the thermal radiation effect of nuclear detonations in flat terrain and snow shelters will be vulnerable to blast effects. Heavy snow and hard-to-maneuver terrain will slow troops in traversing areas contaminated by induced and residual nuclear radiation. When used in deep snow, impact-detonating chemical ammunition burns in the snow and the chemical agent tends to be smothered by the snow. Toxic chemical munitions produce less vapor concentration because of the low temperature and the smothering effect of the snow. On the other hand, low temperatures increase the persistency of toxic chemical agents in both vapor and liquid form. Decay of biological agents is not as rapid in arctic areas as it is in temperate or tropical areas.

e. Cover and Concealment. The snow-covered terrain offers few features that provide adequate concealment and cover. Tracks in the snow are almost impossible to hide, and dirt on fresh snow can be observed at a great distance. Due to the high visibility, effective camouflage is difficult. Because of the difficulties of concealment, night movements are frequently advisable.

f. Obstacles. During the winter months, the lakes, swamps, and rivers are frozen over and cannot be employed as natural obstacles. Artificial obstacles may be devised by freezing large masses of snow or icecrete (a dense frozen mixture of water, sand, and sometimes, gravel) into desired shapes, or by icing deep drifts. Roadblocks may be made by icing a section of the road, preferably one which the enemy must approach on an upgrade. Tank traps may be devised by cutting the ice on a lake or river, then allowing it to refreeze slightly.

g. Avenues of Approach. Winter is generally the best time to travel in the Arctic and sub-

arctic, since the lakes, streams, and muskeg areas are frozen over. Frozen rivers and water ways often become the best routes of advance and lines of communications during the winter months. In general, most vehicles are immobilized in snow from 1 to 1.5 meters (3 to 5 feet) deep. The consistency of the snow, whether it is dry and loose, moist, or packed, affects the mobility of vehicles to a great extent. Tracked vehicles usually can move at low speeds in packed snow that is no more than 1 meter (3 feet) deep. After a packed snow trail has been formed by the passage of several heavy vehicles, normal speeds may be maintained. A thaw or the passage of a great many vehicles on a relatively warm day will melt the snow surface, resulting in a coating of glare ice. The road then becomes practically impassable to tracked vehicles unless ice cleats are installed on the tracks or the road is sanded. Foot movements are slow in 50 centimeters (20 inches) of snow and impossible in more than 100 centimeters (40 inches) deep without the use of snowshoes and skis. Hard-packed snow, however, is not difficult for troops to negotiate. With reasonable care lakes and streams may be crossed by vehicles in winter. The ice first must be checked for thin spots, cracks, and pressure ridges. During the spring thaws, movement in ice and snow across tundra is difficult and dangerous and cross-country movement is practically impossible. After the snow cover has melted from the ground, both wheeled and tracked vehicles can move relatively freely on it as long as the surface remains frozen. This layer of ground that thaws in the summer and freezes again in the winter is termed the active layer. As soon as the active layer has melted, the tundra cannot support heavy concentrated loads and ordinary vehicles will bog down. Even special-purpose vehicles become roadbound during the thaw period and cannot move across the tundra.

CHAPTER 5

NATURAL TERRAIN FEATURES

Section I. SIGNIFICANCE

51. Definitions

a. Topography. Topography refers to the physical features, both natural and manmade, of the earth's surface. In terrain analysis, the following categories of topographical features are considered: relief, drainage, surface materials, vegetation, special physical phenomena, and manmade (cultural) features. Terrain refers to a consideration of topography in terms of military significance. Weathering and erosion play a major role in shaping natural features (fig. 13). Weathering comprises the effects of the weather elements and erosion includes the action of running water, waves, moving ice and snow, and wind upon rock and soil.

b. Landforms. Landforms are the physical expression of the land surface. The principal groups of landforms are plains, plateaus, hills, and mountains. Within each of these groups there are surface features of a smaller size, such as flat lowlands and valleys. Each type results from the interaction of earth processes in a region with given conditions as to climate and as to kind and structure of rock. The indications of relative elevations given are to afford specific definitions for the purposes of this manual. Other distinctions may be found in other references. A complete study of a landform includes determination of its size, shape, arrangement, surface configuration, and relationship to the surrounding area.

c. Relief. Relief refers to the irregularities of the land surface. Local relief indicates the difference in elevation between the highest and lowest points in a limited area and the size of this area depends upon the purpose for which the surface is being considered. In terrain studies, it is usually five square miles. Relief features are the individual forms of the land surface, such as hills or ridges and major relief features are plains, plateaus, hills and mountains. Minor relief features include:

(1) *High ground*—swells, knolls, mounds, knobs, hummocks, hillocks, spurs, ridges, buttes, mesas, and dunes.

Figure 13. Landforms caused by erosion in arid climate (a) Pinnacle. (b) Butte (Grand Canyon, Arizona).

(2) *Depressions*—gullies, draws, gulches, wadis, ravines, gorges, arroyos, canyons, and basins.
(3) *Breaks in high ground*—saddles, notches, cols, passes, cuts, and gaps.
(4) *Special features*—alluvial fans, talus slopes, talus cones, and boulder fields.

52. Military Operations

a. Influences. Terrain influences strategy and tactics. What aspects of the terrain are most important at any given time will depend upon the particular requirements of the command concerned. Logistic requirements, for example, may emphasize the importance of communication centers, routes and rail nets, and waterways. The tactics of a large-scale campaign may be dictated chiefly by the barriers imposed by major rivers and lakes, mountains, forests, or swamps.

b. Attack. In the attack, the correct use of terrain increases fire effect and diminishes losses. Dominant terrain forms the framework of the system of observation, which in turn directly determines the effectiveness of supporting weapons, the disposition and control of the attacking forces, the selection of objectives, and protective measures. Broken terrain, dense woods, built-up areas, and abrupt changes in elevation hinder the offensive employment of armor but afford cover and concealment for infantry. Open, rolling terrain, although providing little cover and concealment for infantry, is suitable for rapid advances by armored formations. Soil trafficability may be a determining factor in selecting type of attack or an avenue of approach.

c. Defense. The nature of the terrain is a major factor influencing the commander when deciding upon position defense or a mobile defense. When the terrain restricts the ability of an attacking enemy to maneuver and provides natural lines of resistance, a position defense may be desirable and of course, terrain that facilitates maneuver by defending forces will favor a mobile type of defense. In selecting the key areas for defense, the commander depends largely upon a terrain study. In addition, a terrain study frequently will give valuable indications of probable enemy assembly areas, field and air defense, artillery positions, observation posts, and avenues of approach.

d. Retrograde. In retrograde, good observation and fields of fire permit engagement of the enemy at long ranges. Natural and artificial obstacles are exploited to strengthen defenses, protect exposed flanks, and impede the enemy advance. Concealment and cover are essential for assembly areas and routes of movement. Road nets are exploited to expedite the movement of friendly forces and to facilitate control, and are denied to the enemy for the same reasons. The effects of weather on the terrain influence observation, trafficability, control, and the performance of troops and equipment.

e. Nuclear. The maximum effects of a nuclear weapon are subject to many variables, depending on how the weapon is employed. Blast and thermal effects would extend to a greater distance in open terrain, but the missile effect and thermal fires obtained with a certain height of burst could create many adverse conditions, such as tree blowdown, induced radiation, and immediate residual radiation.

Section II. LANDFORMS

53. Plains

a. Definitions. As a landform group, plains are generally flat to rolling areas with uplands or interstream areas less than 150 meters (500 feet) above adjacent valley bottoms. A dissected plain is one with a surface that is interrupted by erosional features, and an undissected plain is one with a smooth uninterrupted surface.

b. General Characteristics. Plains may be situated at any elevation. Some are thousands of feet above sea level and others are at sea level. Some are rough and rolling and others are flat. Because of their low degree of local relief, plains generally have low angles of slope. In temperate climates, this characteristic makes them favorable for transportation routes. Where there is monsoon weather or a tropical climate, however, more reliable routes may be provided by higher terrain. The details of relief include uplands and lowlands, ridges

and valleys, and hills and hollows, all within local ranges of elevation of 150 meters (500 feet) or less.

c. *Classification.* Plains are classified as—

(1) *Flat.* Local relief of less than 15 meters (50 feet).

Figure 14. Coastal plain formed by volcanic lava (Hawaii).

Figure 15. Outer delta features (Moses Point, Alaska).

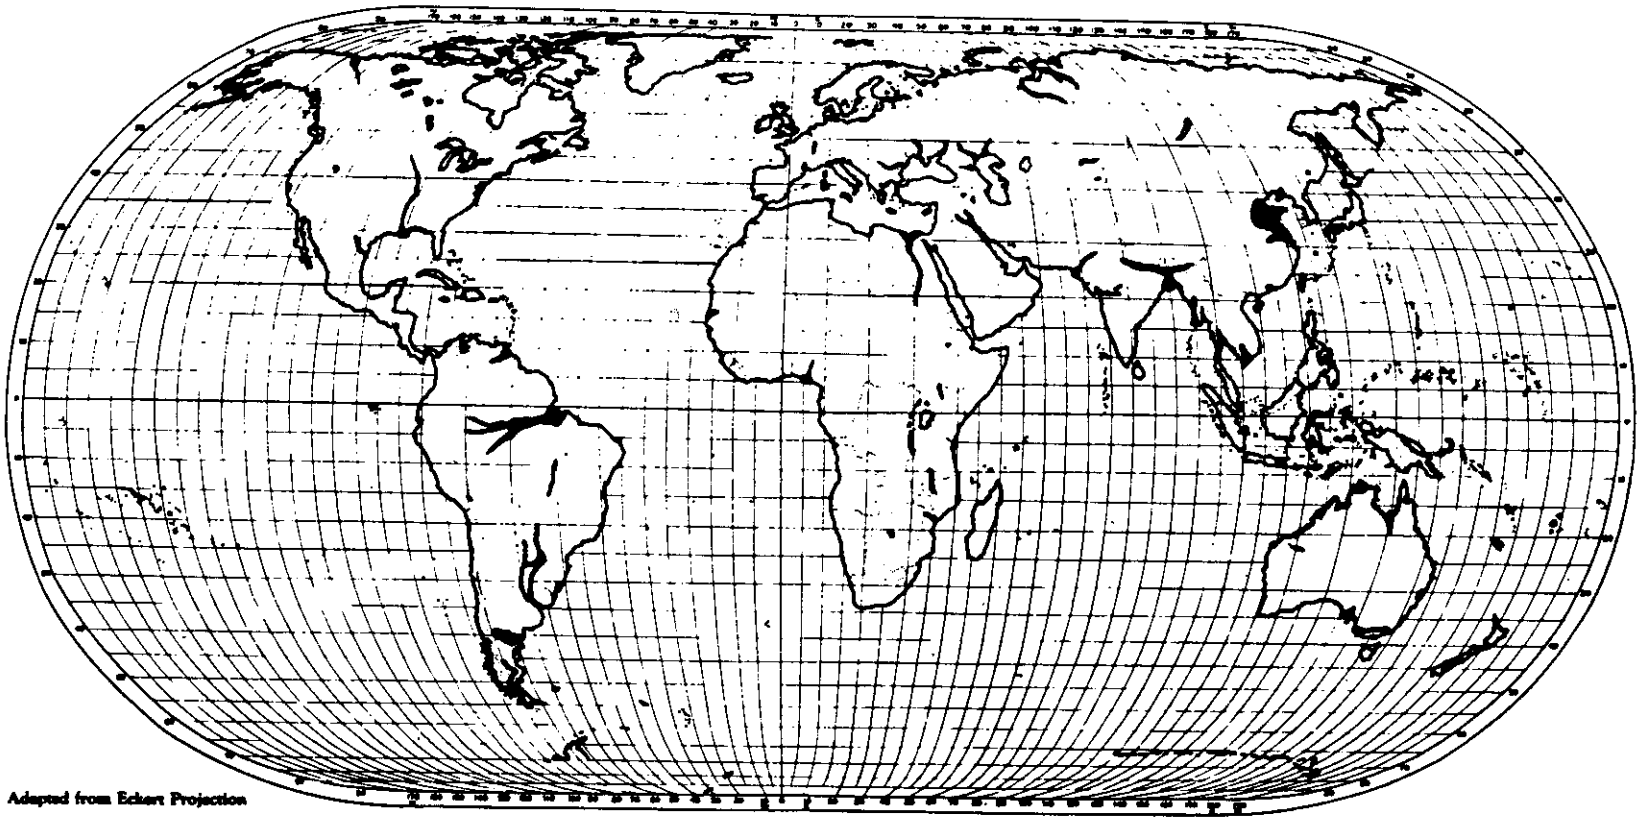

Figure 16. Flood plain, terrace, and delta deposits of the world.

(2) *Undulating.* Local relief of 15 to 45 meters (50 to 150 feet).
(3) *Rolling.* Local relief of 45 to 90 meters (150 to 300 feet).
(4) *Roughly dissected.* Local relief of 90 to 150 meters (300 to 500 feet).
(5) *Slope.* In terms of slope, plains are considered smooth when they have large areas with a slope of less than 2 percent, and rough when there are large areas with a slope of more than 2 percent or many small areas with steep slopes.

d. Coastal Plains. These are generally low and featureless (fig. 14). Frequently they have shallow valleys formed by streams that originate inland. Swamps usually are numerous. Cuestaform coastal plains are characterized by long, low ridges alternating with lowlands in bands several miles wide and many miles long generally parallel to the coast. The ridges on this type plain are usually asymmetrical, the steeper slope being inland.

e. Delta Plains. These plains, which are formed by sediments deposited at the mouths of streams and rivers, are usually low and marshy, with a local relief of less than 15 meters (50 feet) (fig. 15). The features of greatest relief are the natural levees, which are low, broad banks of alluvium on either side of the stream channels. For protection against stream overflow, artificial levees may be built near the stream on top of the natural levees.

f. Flood Plains (fig. 16). These, also called

Figure 17. Meandering river, showing flood plain and oxbow lakes.

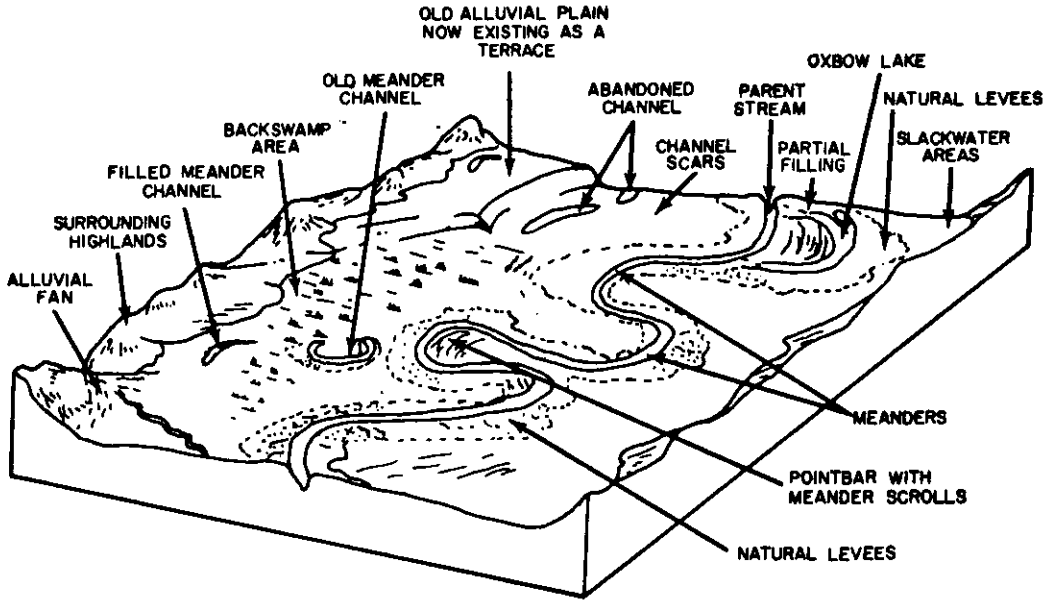

Figure 18. Flood plain with evidence of pre-existing meander.

alluvial plains, are formed by weathered and eroded material deposited by streams upon the floors of their valleys. The flood plain usually is poorly drained, and may contain marshes, swamps, lakes, and former stream channels. Unless protected by levees, it may become partly or completely covered by water in times of flood. The surface is flat, the levees alternating with swamp areas. Meandering rivers and crescent-shaped (oxbow) lakes are characteristic of this type plain (fig. 17 and 18). The silts and clays deposited on flood plains make productive soils, and this type plain is used extensively for agriculture.

g. Piedmont Plains. These are alluvial plains formed by mountain streams with steep gradients that deposit a sediment, consisting largely of gravel and sand, at the point where the stream enters the lowlands. This type of plain is found in arid and semiarid regions with meager vegetation and torrential rains. Although the plain may appear level, actually it slopes away from the mountain base. Many piedmont alluvial plains are covered only with shrubs or sparse grasses. Those with fine soils are high in mineral plant foods and, if irrigation water is available, they are suitable for agriculture.

h. Glacial Plains. These (fig. 19 and 20) are classified as either ice scoured or drift plains.

(1) Ice-scoured plains are level to gently rolling areas composed largely of bare rock. They are characterized by rounded rock hills and broad open valleys and basins with comparatively low local relief. Over the valley floors there may be a thin covering of glacial debris which serves as an anchorage for shallow-rooted trees, chiefly conifers. There are numerous falls, rapids, and lakes. Some small shallow lakes become filled with remains of marsh vegetation, such as sphagnum moss, creating bogs of the type called muskeg in Canada.

(2) Drift plains consist largely of boulders, gravel, sand, or clay in layers of varying thickness on top of other strata of rock and soil. The principal characteristic is a gently undulating surface which includes broad, low hills, or swells, and wide, shallow depressions, or swales. Commonly the local relief is less than 30 meters (100 feet). Large areas of drift plains are essentially flat, with poorly developed natural drainage. Although soils are generally heterogeneous mixtures,

Figure 19. Glacial plain (Moose Jaw, Saskatchewan, Canada).

areas of impervious clays are common. After heavy rains, ponds several acres in extent may form; and unless artifically drained, the water may stand until it evaporates. In some localities there are hills of clayey till called drumlins (fig. 21) that occasionally reach heights of more than 30 meters (100 feet) and may be a mile long. Streams in this type of plain may be interrupted by swamps, lakes, falls, or rapids.

i. Lacustrine Plains. These are formed by sediment settling on lake bottoms. Subsequently the lake was drained by natural forces, or evaporated because of a major change in climate. They are level and often contain salty or alkaline lakes. Generally they are characterized by poor drainage and alkaline soils.

j. Loess Plains. These are formed by windblown particles of silt, called loess, which have been deposited over large areas, forming a smooth, gently sloping surface. The ability of loess to stand in vertical walls results in steep escarpments along gullies, stream valleys, and artificial cuts (fig. 22).

k. Karst Plains. These (fig. 23) are a type of erosional plain developed on limestone. They have a pitted surface along with exposed bedding plain edges (pinnacles) tilted through the surface. The pitting is formed from subsurface collapsing due to the solvent action of underground water. Between the depressions there are low, irregular ridges or hillocks. Numerous caverns are formed beneath the surface of a karst plain, and there are also large underground streams which may issue at the surface as springs of considerable volume.

54. Plateaus

a. Description. A plateau is commonly bordered by an escarpment or steep slope on at least one side. The plateau surface may be cut by deep, narrow stream valleys, but the interstream areas are mostly broad and nearly level. Tabular uplands with a local relief of more than 150 meters (500 feet) may be considered plateaus. They vary greatly in configuration, but most have broad flat surfaces high above sea level, and are deeply trenched by narrow valleys. Depending upon the stage of the erosion cycle, the valleys that dissect the plateau may be widely spaced early in the cycle or very closely spaced late in the cycle (fig. 24). Most large plateaus are in regions with arid or semiarid climates. Plateaus may be classified into three major types:

(1) *Intermountain* (fig. 25). Surrounded or nearly surrounded by mountains.

(2) *Piedmont.* Lying between mountains and plains, or between mountains and the sea.

(3) *Continental* (fig. 26). Rising abruptly from bordering lowlands or the sea on most or all margins; usually without conspicuous mountain rims.

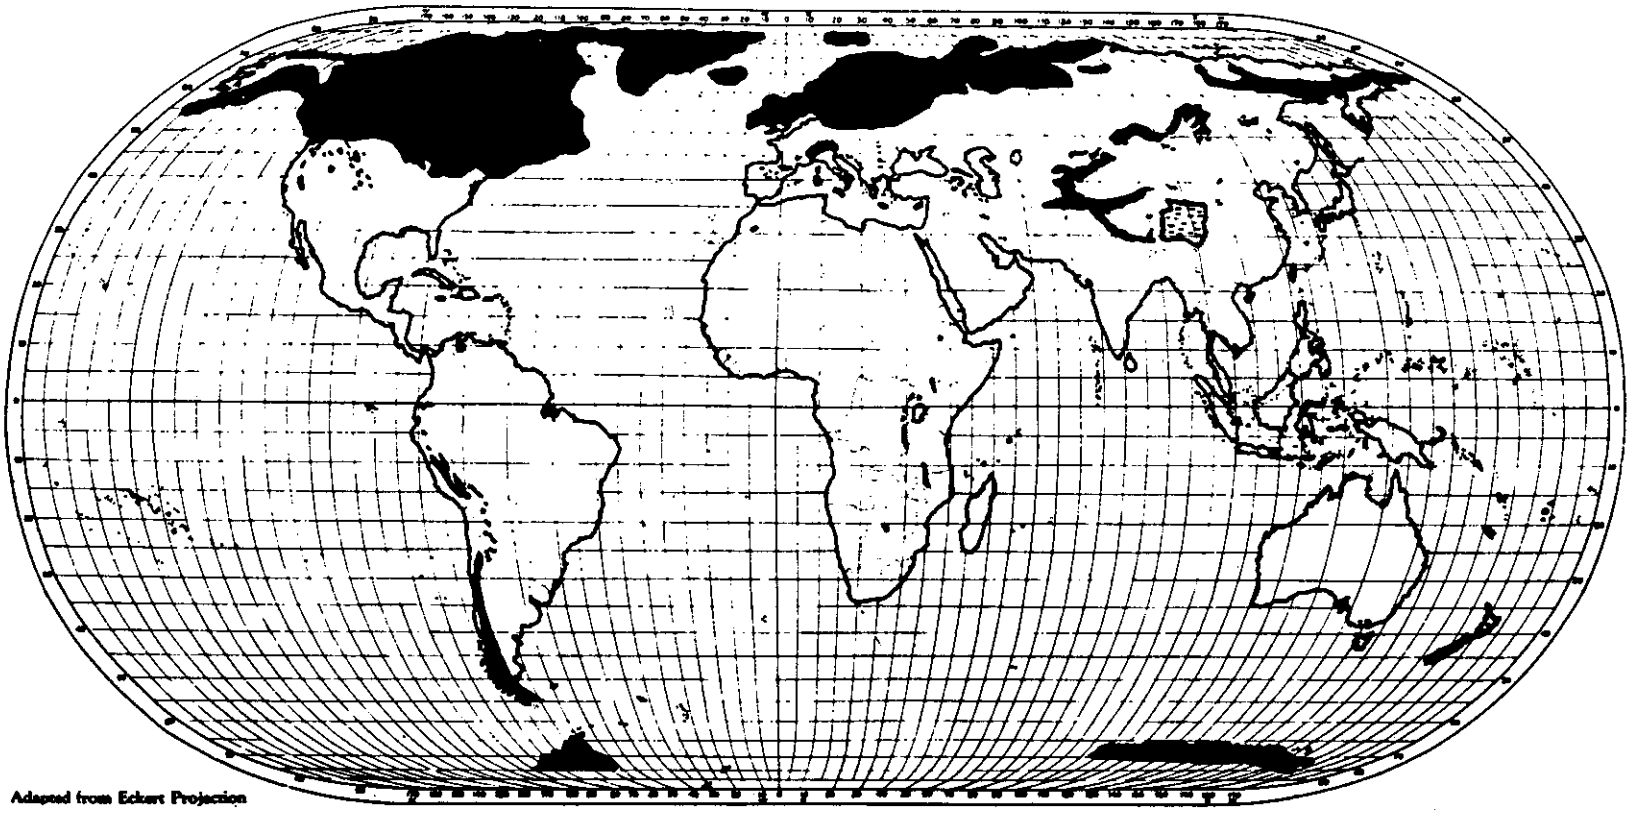

Figure 20. Glaciated areas of the world.

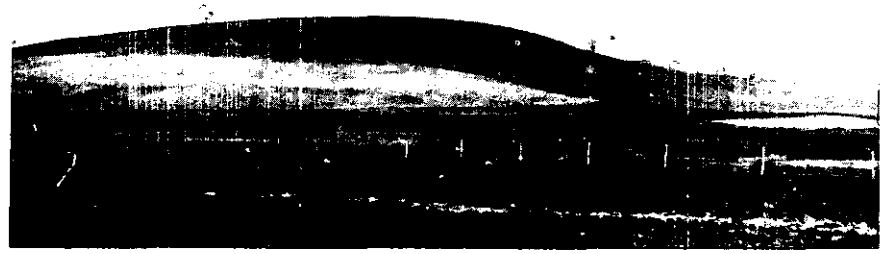

Figure 21. Drumlin (New York).

b. Climates. In arid climates, streams usually flow in canyons cut into the plateau, the typical canyon having a narrow bottom offering little space for a roadway. The stream is seldom navigable and follows a steep, boulder-strewn course interrupted by rapids and falls. Sudden and extensive changes in stream level are common. Canyons usually are too deep to be crossed easily and too wide to be bridged economically. They rarely provide a transportation route and are a difficult obstacle to movement. Areas between the streams usually are flat or rolling uplands, some of vast extent. Areas of interior drainage called bolsons exist on some plateaus. The streams empty into these, resulting in level areas that may contain large salt lakes or salt marshes. Plateaus in humid climates tend to be more dissected by stream erosion than those in arid climates. Broad divides with rounded and irregular uplands are common.

c. Ice Plateaus. The vast sheets of ice that cover most of Greenland and Antarctica may be regarded as great plateaus. Greenland is an intermontane plateau, surrounded by a fringe of mountains. In most of Antarctica, the ice rises in a sheer wall, then slopes up rapidly to a fairly level interior with an average elevation of about 1,830 meters (6,000 feet), the maximum elevation of 3,050 meters (10,000 feet) being found in regions inland from the Pacific coast. In general, the surfaces of an ice plateau are flat or have parallel ridges a few feet in height which result primarily from the wind and drifting snow.

(1) *Marginal features of Greenland.* The highland or mountainous rim and the higher summer temperatures of Greenland produce marginal features which are different from those of Antarctica. The ice is confined by the highlands, melting some distance inland on the southern and western margins. Where ice does not discharge into the sea, it protrudes through gaps in the bordering highlands (fig. 27). Irregular icebergs form, drifting into the Atlantic Ocean during the spring months.

(2) *Marginal features of Antarctica.* The marginal ice of Antarctica is thin and traversed by deep cracks. Except in a few localities where it is retained by the fringing mountains, the ice overruns the land margins, so that the exact position of the continental shoreline is not known. The edge of the ice is marked by sheer cliffs. From these cliffs giant icebergs split off along crevasses as a result of undercutting by waves and the buoyant effect of sea water. Some of these are tens of square miles in area. The icebergs disintegrate by melting and disperse as masses of floe and drift ice which fringe the continent for many miles.

55. Military Effects of Plains and Plateaus

a. Variety. Although plains and plateaus are characterized by relatively low relief compared to hills and mountains, they present a wide variety of topographical conditions. Since each type of plain or plateau differs in its features and effects, one can only generalize about their influences on military operations.

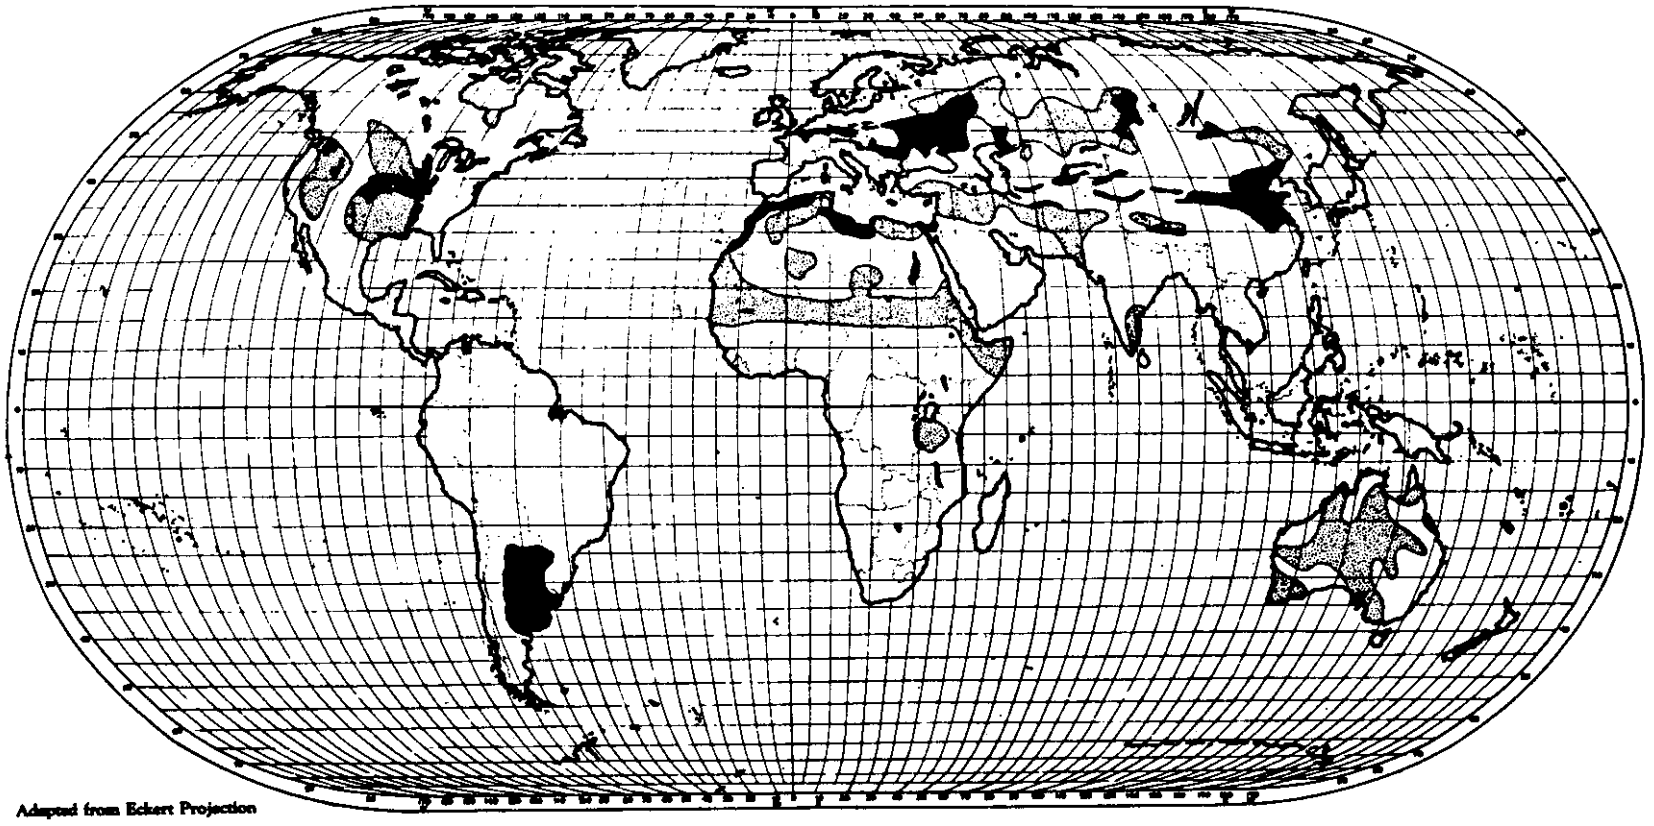

Figure 22. Loess deposits of the world.

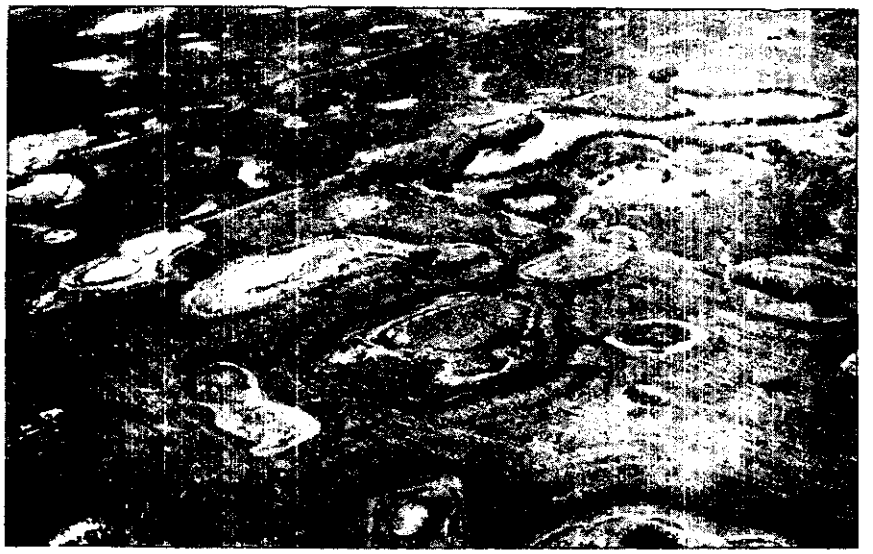

Figure 23. Karst plain (Canada).

Figure 24. Plateau dissected by stream (Deschutes River, Oregon).

b. Movement.

(1) *Coastal plains.* In general, the topography of coastal plains offers no major obstacle to the cross-country movement of tracked vehicles, although there may be areas that are difficult or impracticable because of unfavorable soil conditions and dense vegetation in areas of medium to heavy rainfall. Movement along an indented shore usually is difficult because the terrain is separated into compartments by streams and estuaries. Cross-country movement in-

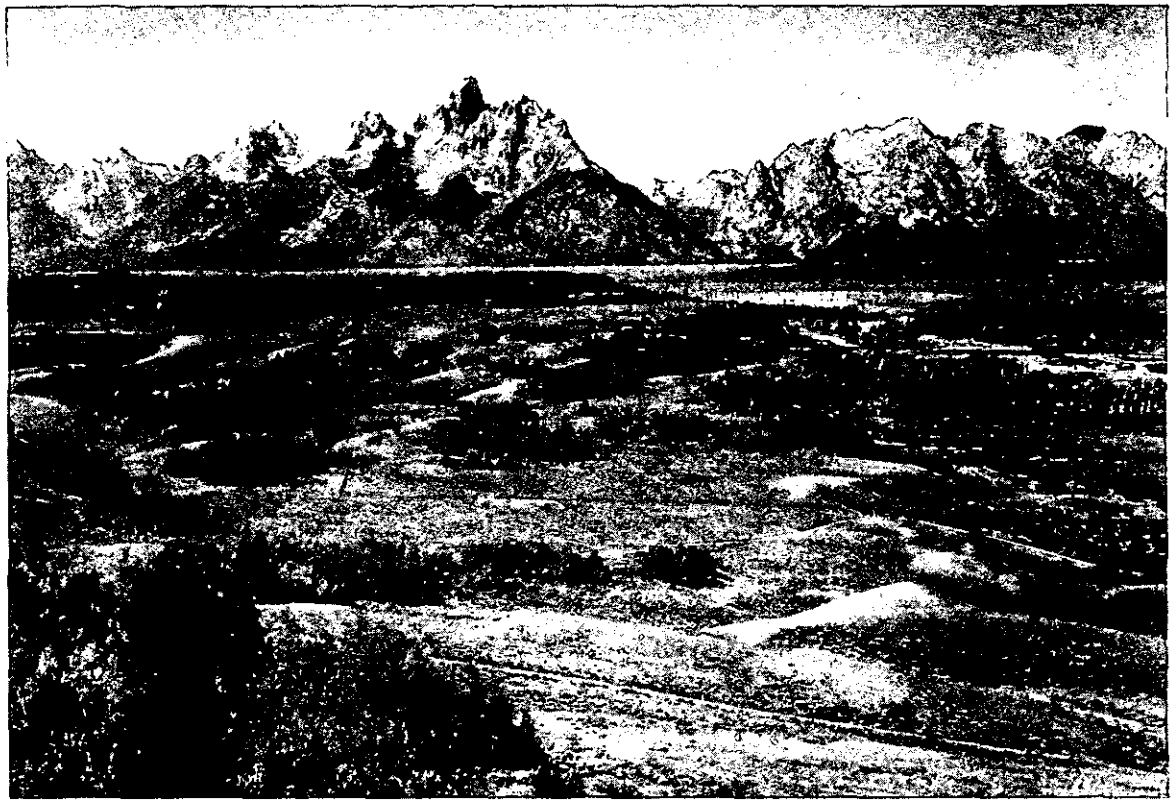

Figure 25. Intermountain plateau (Jackson Hole, Wyoming).

land may be limited to narrow areas bordered by water. In such terrain, attacks may require amphibious support. Coasts with beach ridges hinder an advance inland because vehicles must cross poorly drained areas between relatively stable sand ridges. Terrain of this type impedes the adequate dispersal of troops and supplies.

(2) *Delta plains.* On delta plains cross-country movement usually is hindered by marshy ground, shifting streams with loose sand and mud bottoms, and thick vegetation. Soils are better drained in the inner regions of the delta. Normally the natural levees of streams provide the highest, best-drained, and most trafficable parts of the delta. Movement on the low-lying grounds of delta plains is always threatened by the possibility that the enemy will destroy dikes or levees and flood the area. The use of waterways as avenues of approach by the enemy must not be overlooked.

(3) *Alluvial Plains.* The stream valleys in alluvial plains generally provide corridors through areas of greater relief. In dry weather, the cross-country movement conditions usually are excellent, except for such obstacles as streams and local areas of unfavorable soil or dense vegetation. In wet weather or during floods movement may be limited to small areas of higher, better-drained ground, such as levees. Alluvial terraces are above flood levels and may be well-drained, but they are commonly isolated by steep slopes. It is not unusual for a stream to meander from one side of its valley to the other. If the valley slopes are steep, such meandering may eliminate vehicular movement up or down the valley.

(4) *Glacial plains.* The topography of

Figure 26. Eroded continental plateau (Grand Canyon, Arizona).

glacial plains usually presents no insurmountable obstacles to movement. Large boulders may be obstacles in some area. In regions containing large areas of soft ground, lakes, or marshes, movement in the rainy season may be greatly hindered by mud (fig. 28).

(5) *Lacustrine plains.* No topographic obstacles to movement are offered by the level surface of lacustrine plains (old lake beds). During wet weather, however, the fine soils may be slow-drying and become nontrafficable (fig. 29).

(6) *Loess plains.* Loess is a fine-grained, yellowish-brown silt deposited by the wind. In dry weather, movement conditions on loess plains are good, except where escarpments and ravines

Figure 27. Tongues of icecap descending toward fiord (Greenland).

are encountered. Ground conditions may become very poor in wet weather, making cross-country movement impracticable.

(7) *Karst plains.* Movement on karst plains, a limestone region, is limited chiefly by the sinkholes, which may have steep slopes and contain swamps and ponds. In wet weather the clayey residual soil overlying the limestone may limit movement in some areas. Karst regions vary greatly in their characteristics—from a plain with an occasional sinkhole to a surface so pitted and broken as to make even dismounted movement very difficult. Knowledge of the erosional development is necessary to evaluate such an area properly.

c. Observation. The degree of observation available on coastal plains is normally good along the coastline, but inland the flat country and forest cover usually offer few observation points. Observation is limited on delta plains because the low, level ground generally is covered thickly by vegetation. On alluvial plains, observation from the valley bottoms usually is poor, but the bordering regions provide commanding views into the valleys. Where vegetation does not interfere, it may be good on the more level portions of these plains. Vegetation also determines the amount of observation that may be secured in lacustrine, loess, and karst plains.

d. Cover and Concealment. Coastal plains provide few areas with sufficient cover and concealment for larger units. Except for the levees, there are also few topographic features on delta plains that will conceal or protect troop bodies of any size. Little cover and concealment are available on alluvial plains, except for that provided along terraced scarps, river banks, and levees. On glacial plains, cover is lacking in the more level parts, but there may be some limited cover and concealment provided by knobby and forested areas. The sinkholes of karst plains also provide a moderate degree of concealment and cover.

e. Construction.

(1) *Coastal plains.* Although generally there is no hard rock on coastal plains, sand and gravel are abundant on beaches and along streams. The ground of coastal plains is excavated easily, but the depth of excavation usually is limited by the high water table. Long and straight road aline-

Figure 28. Glacial boulders (Yosemite National Park).

ments normally can be obtained. There are many suitable sites for airfields, particularly along the marine terraces.

(2) *Delta plains.* Abundant sand and fine binder material may be obtained on delta plains, but gravel is scarce. There are no exposed hard-rock formations or bedrock. Generally the location of airfields and roads must be confined to the levees. Structural foundations not built upon levees are unreliable, and may settle due to the low, poorly-drained ground with a threat of periodic flooding. Drainage always is a serious problem because the levees prevent the return of surface water to the river, and the high water table limits underground return. Accordingly, drainage and pumping systems may be required.

(3) *Alluvial plains.* Rock is scarce in flood plains except where it may crop out along the scarps of terraces. Sand, gravel, and binder material are abundant along stream channels and the terrace scarps. Terraces also may provide suitable sites for bunkers and underground installations. Excavations in flood plains are limited by the high water table, but these plains and terraces if well-drained are suitable for the construction of roads and airfields.

(4) *Glacial plains.* Sand and gravel are

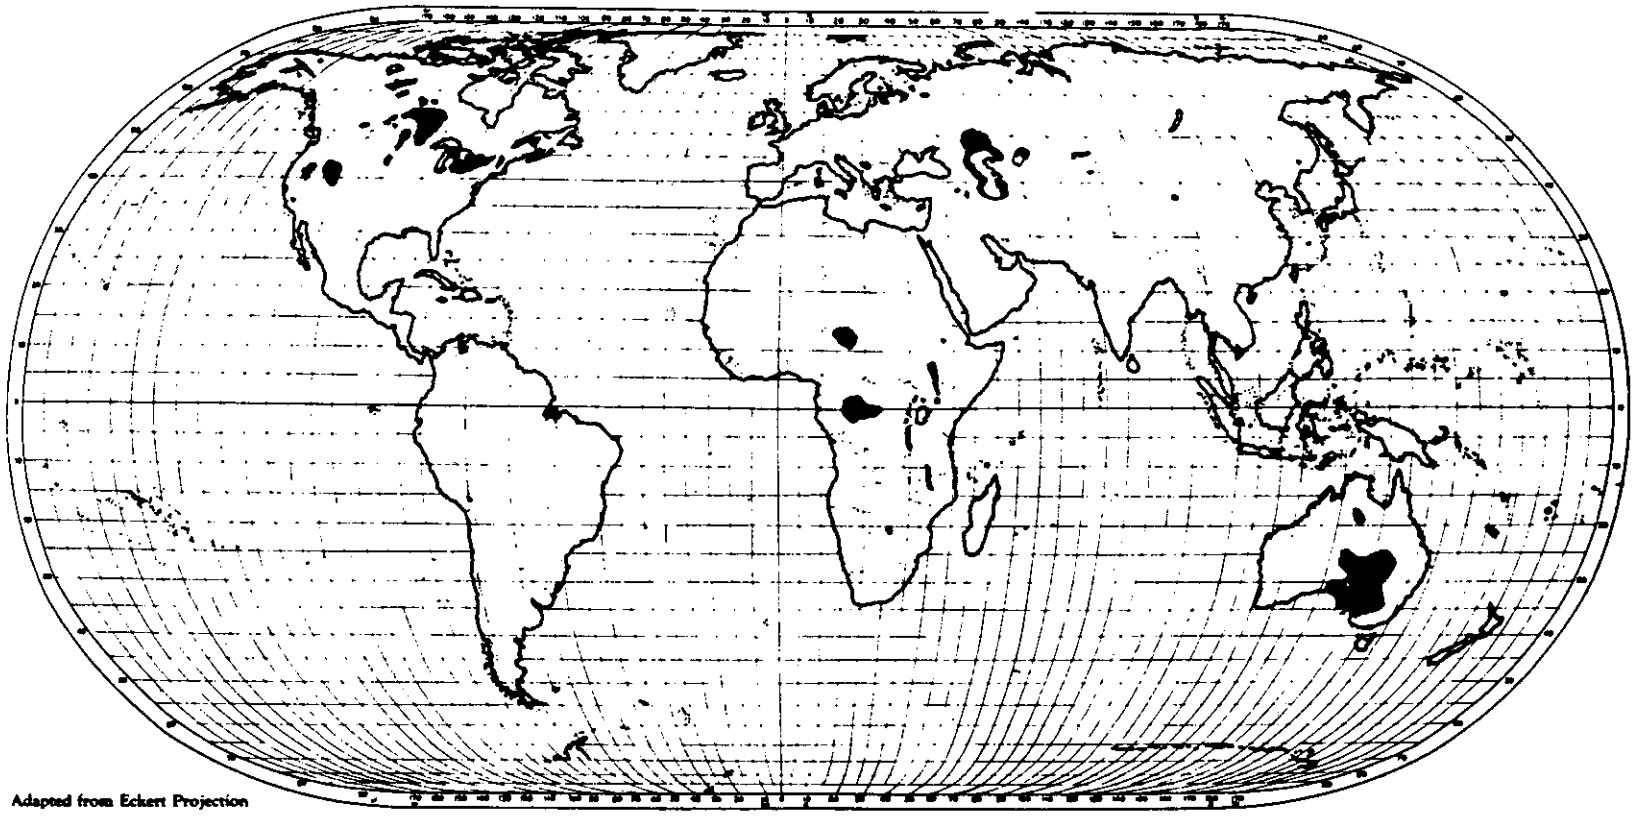

Figure 29. Lake bed and related deposits of the world.

widely distributed on glacial plains, and rock usually is abundant. On till plains, boulders may provide building stone, but there is bedrock only in a few locations, such as in deep valleys where the overlying till has been cut through. Wet ground and weak soils may create foundation problems where the drainage is not good.

(5) *Lacustrine plains.* Except at the marginal slopes, where sand, gravel, and rock may be obtainable, lacustrine plains usually can provide only clay and fine sand for construction purposes. The fine-grained soil makes a poor foundation for structures, particularly in humid climates. Lacustrine plains provide level sites for airfields with few natural obstructions and allow unrestricted road alinements.

(6) *Loess plains.* Loess plains are a poor source of gravel or rock, except where there are underlying deposits. Foundations require stabilization and in cold climates the loess may heave. In dry climates, thick loess deposits are easily excavated and are well suited for underground installations. Many good airfield sites and road alinements usually are available.

(7) *Karst plains.* Large quantities of limestone for building stone and crushed rock may be obtained on karst plains. Sand and gravel usually are lacking. Excavation often is difficult because of the irregular rock surface, with deep clay-filled pits, and the high pinnacles of rock that lie beneath the residual soil. Grading usually requires the excavation of rock. There is always a possibility of foundation subsidence.

56. Information Requirements — Plains and Plateaus

a. Plains.

(1) Extent of area covered by plain.

(2) Surface (elevation, slope, kind of surface).

(3) Major interruptions (hills, mountains, river valleys).

(4) Minor interruptions (gullies, sinks, levees).

b. Plateaus.

(1) Area covered by plateau.

(2) Surface (elevation, slope, surface, relief features).

(3) Major interruptions (hills, mountains, canyons, valleys).

(4) Margins (mountains above plateau, abrupt descending cliffs).

57. Mountains

a. Description. As a landform group, mountains are rugged areas with crests that are, in general, more than 600 meters (2,000 feet) above adjacent lowlands. They are commonly distinguished from other major relief features by the predominance of slopes and their overall massiveness. In terms of local relief, mountains may be classified as low when they have a local relief of 900 meters (3,000 feet) or less, and high when their height exceeds that figure. According to their size and arrangement, mountain features may be classified as peaks, ranges, chains, and cordilleras.

b. Peaks. A peak is a conical high mass, that rises above its surroundings. Ordinarily a peak is a feature of minor order upon a range, but as in the case of an isolated volcanic cone, one peak may stand alone and comprise the entire mountain mass.

c. Ranges. A range is an arrangement, usually linear, of many peaks, ridges, and their valleys. The term ordinarily applies to mountains that have a general unity of form, structure, and geologic age.

d. Mountain Chain. A mountain chain consists of several associated ranges, usually more or less parallel, having unity of position, form or structure, but separated by trenches or basins.

e. Cordillera. A cordillera is a large regional grouping of mountain chains.

58. Mountain Features

a. Relief. Mountains are distinguished from hills by their greater relief, more rugged contours, and more complicated surface patterns. The average slope of large mountains seldom is more than 20° to 25° from the horizontal, and only a few have slopes of more than 35° near the summit. Even walls that seem vertical seldom have slopes that average more than 70°.

b. Valleys. Except where they have reached grade level and meander in flat alluvial valleys, mountain streams have high gradients and flows of high velocity. The rapid downward cutting action of the stream may uncover bedrock of unequal hardness, so that falls and rapids develop. Some streams, in cutting through bedrock of unequal resistance, erode valleys which are broad at their headwaters, then narrow to gorges, and subsequently open out again downstream. Valleys formed by glacial action have wide rounded bottoms and steep sides. They have U-shaped profiles, in contrast to the V-shaped profile of a stream eroded valley. The walls are steep and rugged. Most glaciated valleys have one or more basins in which impounded drainage creates lakes, ponds, or marshes.

c. Divides. Between the mountain valleys there are uplands formed by remnants of the original elevation. Rainfall on these uplands separates according to the surface slopes and descends by numerous rivulets into adjacent valleys, modeling the uplands as it flows. The uplands are called divides. When they separate the drainage destined for opposite sides of a continent they are termed continental divides.

d. Foothills and Spurs. The lowest and least massive features of mountain uplands are the foothills and spurs that fringe the principal highlands. Foothills are hills located at the base of higher mountains or hills. A spur is a ridge projecting laterally from the main crest of a hill or mountain.

e. Passes. The erosion by streams or glaciers creates saddle shaped notches, or passes, in a mountain barrier. The term pass is applied to any type of natural passageway through high, difficult terrain.

59. Hills

As a broad landform group, hills are rough areas with crests generally from 150 to 600 meters (500 to 2,000 feet) above adjacent lowlands. They usually contain a predominance of moderate slopes. Hills may be classified as low when they have local relief of from 150 to 300 meters (500 to 1,000 feet), and high, when the local relief is from 300 to 600 meters (1,000 to 2,000 feet). Some very rough hills may appear mountainous in relation to adjacent plains, and locally may be called mountains, but they are not properly of a size or nature to merit the term. Mature hill lands may be almost entirely a succession of hills, valleys, and narrow ridges, with level land occupying less than five percent of the total area. Hill regions in an early stage of erosion may include some fairly level, plateaulike uplands separated by steep-sided valleys. Those in a more advanced erosional stage may have broad open valleys and reduced slopes that are suitable for agriculture. Because some of the slopes in hill regions are steep and untillable, they have retained their forest cover and have streams with steep gradients that are capable of developing waterpower.

60. Military Effects of Hills and Mountains

a. Key Terrain Features. In both attack and defense, the key terrain features may include the heights which dominate valleys, the routes of communications, passes and valleys which permit cross-country movement through the mountains, and aircraft landing areas. Dominating heights which may be used by the enemy for observation of avenues of approach must be controlled.

b. Observation and Fields of Fire.

(1) *Observation.* In hilly and mountainous areas, observation may be restricted. In most cases, commanding heights provide only partial observation of adjacent valleys and slopes. Foothills and spurs extending into a valley obscure observation along the valley.

(2) *Fields of fire.* Mountains and hills place some restrictions upon the em-

ployment of supporting weapons. Armor loses much of its mobility because it cannot move across country. Occasionally tanks can be used in small numbers against limited objectives, but their action often is confined to providing direct fire support. Artillery is effective, but the limited visibility in mountainous terrain restricts observation and adjustment of fire. Terrain features may also reduce the effectiveness of air defense artillery by making radar siting difficult and reducing the target acquisition range of the system. Survey and fire control are hampered, and more time is required for artillery to displace. There is difficulty in finding gun positions that do not have too much defilade. The heavier crew-served weapons of the infantry and their ammunition are difficult to carry over the rugged terrain. Mortars and recoilless rifles are effective and are favored for operations in mountains and hill regions. Deep valleys and ravines afford a degree of protection from the blast effect of nuclear weapons when the axis of the valley or ravine points well away from ground zero. When it does not, there is little or no shielding effect, and blast damage may be increased because the blast is canalized. Deep valleys and ravines afford substantial protection from thermal and nuclear radiation to troops, materiel, and buildings located within the shaded portions. In terrain characterized by deep valleys and ravines, however, blast effects of nuclear weapons may cause serious avalanches and rock slides. Concentrations of toxic chemical agent aerosols are extremely hard to achieve on marked downward slopes. Toxic chemical agents and biological agent clouds tend to flow over rolling terrain and down valleys, to remain in hollows and on low ground and in depressions, but to go around obstacles. Local winds, coming down valleys at night or up valleys in the daytime, may deflect the clouds or reverse the forecast flow; likewise they may produce favorable conditions for cloud travel.

c. Cover and Concealment. The rugged topography of mountains offers abundant cover and concealment, although movement across slopes or crests above the timberline will be exposed. Sounds carry from valley bottoms to hilltops, but within the valley, sounds are muffled by ground forms and streams.

d. Obstacles. Major obstacles to movement include steep, high ridges and ranges, high valley routes and escarpments, sloping cliffs and terrace faces. Minor obstacles include stream embankments, valley terraces and benches, spurs, talus, and debris-choked valleys, and presence of boulders.

e. Avenues of Approach. Hills and mountains parallel to the axis of advance offer flank protection, but limit lateral movement. When perpendicular to the axis, they are an obstacle to the attacker and an aid to the defender. Mountain roads must be improved because the roads are generally narrow, have steep grades, and poor surfaces. Sharp turns may prevent the use of trailers. Roads in valleys or along defiles require that the adjacent high ground be secured to insure control of the roads. Mountain roads are subject to slides and may be blocked by snow. Those on the crest of ridges may be exposed to enemy observation. Roads in defiles may be flooded and may also have large boulders. The best sites for military roads in mountain areas are normally on the sides of slopes.

f. Communications. Hills and mountains contain dead spaces that often limit the range and effectiveness of radios, although these restrictions usually can be overcome by the use of relay sets. Wire laying is difficult, and visual signals are not always dependable and often can be seen by the enemy.

g. Air Support. The hazards in mountainous regions place limitations upon the use of low-flying combat aviation. Targets are difficult to locate and in many cases close air-support strikes must be controlled by aerial FAC's (Forward Air Controllers) or by indirect

means, since the functions of tactical air-control parties are hindered by the terrain and weather.

h. Combat. Combat in mountains and hilly areas usually consists of a series of independent actions to seize and hold key terrain, strike communication lines, and protect friendly routes of supply and evacuation. Infantry plays the dominant role, since it is not roadbound and can close with the enemy under any condition of terrain. Commanding positions in mountain terrain are often rocky ridges or eminences with little or no soil. If the importance of the position justifies the time and effort required, trenches, emplacements, and galleries can be cut into the solid rock. Parapets and breastworks of cobbles and boulders are effective against small arms, but they are vulnerable to artillery fire. Log breastworks and protective shelters may be built if timber stands are conveniently located. Mines and obstacles find their most important use in obstructing movement on roads and trails and through defiles. Roadblocks are effective because of the difficulty of bypassing them. Mountain terrain favors the defender because available obstacles enable him to use minimum troops to deny the attacker the use of existing routes. He can force deployment of major enemy units and the expenditure of large amounts of mortar and artillery ammunition, and can inflict the maximum punishment from protected positions.

i. Construction. Hard rocks suitable for construction purposes are readily obtained in hills and mountains. Sand is scarce, but gravel may be secured in the lower stretches of streams where they approach the foot of the mountains or flow through hills. There are few suitable locations for airfields because of the difficulty of excavation in rock, the obstructed and limited approaches, the poor accessibility, and the turbulent air currents. Highways, railways, and tunnels are vulnerable in these areas. Geologic data may be useful in indicating rock conditions favorable to initiating rock slides by bombing or artillery fire to block enemy lines of communication. Geological information will also assist in selecting sites for gun emplacements and other fortifications, in estimating the probable effect of fire on rock fragmentation, and determining the possible ricochet effects of projectiles. The soil usually is thin or stony, with underlying bedrock, so that it is difficult to construct field fortifications. Geologic study will assist in selecting areas where excavations may be made and in choosing the required explosives and equipment.

61. Information Requirements — Hills and Mountains

a. Extent and Type of Mountains or Hills.

b. Ridge Crests.

(1) Location and orientation.

(2) Elevations (typical, highest, lowest).

(3) Height above adjacent valley flats (average, highest, lowest).

(4) Pattern (long straight, parallel ridges; branchlike and crooked ridges; clusters of knobs and peaks).

(5) Skyline (flat-topped and broad, or knifelike).

c. Slopes.

(1) Shape (convex, concave).

(2) Angle, in percent or degrees (near crest, middle, near base).

(3) Minor relief features (rough lava, boulder fields and gullies).

d. Valley Flats.

(1) Location.

(2) Width (of main and tributary valleys; average, widest, narrowest for both categories).

(3) Pattern (long, straight, and parallel valleys or branchlike and crooked valleys).

(4) Transverse profile (degree of slope near center and margin of valley).

(5) Longitudinal profile (degree of slope near mouth and head of valley).

(6) Terraces (benchlands) along borders of valley flats (number of terrace steps, width, continuity, elevation of steps one above another, slope between terrace levels).

(7) Stream channels within valley (straight or meandering, bordered by bluffs, gentle downslopes, or natural levees).

e. Intermontane Basins.

(1) Location.

(2) Width (average, widest, narrowest).

(3) Shape (round, oval, long and narrow, irregular).

(4) Flat bottom lands (extent and location).

(5) Terraces (benchland) about borders of flat bottom lands (number of terrace steps, width, continuity, elevation of steps above one another, slope between terrace levels).

f. Passes.

(1) Location.

(2) Elevations (average, lowest, highest).

(3) Number of passes (distance between passes).

(4) Gradients (near head of pass, downslope).

(5) When closed by ice and snow.

(6) Character of defile formed by pass and approaches (width, length, character of slopes).

(7) Routes over each pass.

Section III. DRAINAGE

62. Effects of Drainage

a. Description. The water features of an area comprise its drainage. They include streams and canals; drainage and irrigation ditches; lakes, marshes, and swamps; artificial bodies of standing water such as reservoirs and ponds, as well as such subsurface outlets as springs and wells. The character of these drainage features is determined by precipitation, relief, surface runoff and ground-water flow, and various manmade improvements. Vegetation has a major influence upon drainage. Dense grass and tree growth on slopes tend to slow up and absorb a considerable amount of the runoff, but slopes with few trees and sparse vegetation permit rapid runoff and the formation of channels by erosion.

b. Catchment. A catchment basin or catchment area is the total area drained by a stream or system of streams. All water features within this area are related and are considered as a whole. The limits of the drainage basin are marked by the topographic divide which separates it from neighboring drainage systems. The amount of water reaching the stream, reservoir, or lake depends upon the size of the area, the amount of precipitation, and evaporation and transpiration. The rate of evaporation depends upon the temperature, vapor pressure, wind, and solar radiation.

c. Patterns. Drainage patterns (fig. 30) reflect the subsurface structure. They are of three major types—dendritic, trellis, and radial defined as follows:

(1) A *dendritic* drainage pattern is a treelike arrangement of streams found most frequently in an area underlain by homogeneous rock.

(2) The *trellis* pattern results from the influence of tilted alternating strata of weak and resistant rocks. The resistant strata separate each stream, producing the overall trellis effect.

(3) The *radial* pattern has streams that radiate from a central dome that lies within a relatively flat area.

63. Rivers and Streams

a. Perennial Stream. A perennial stream flows throughout the year. The regular flow may result from a spring lake or a glacier at the head which furnishes a constant supply of water, from direct precipitation of fairly constant quality, or because the beds are deep enough to be permanently below the fluctuating upper level of the ground water or water table.

b. Intermittent Stream. An intermittent stream originates in a source of water that fails periodically and is particularly common

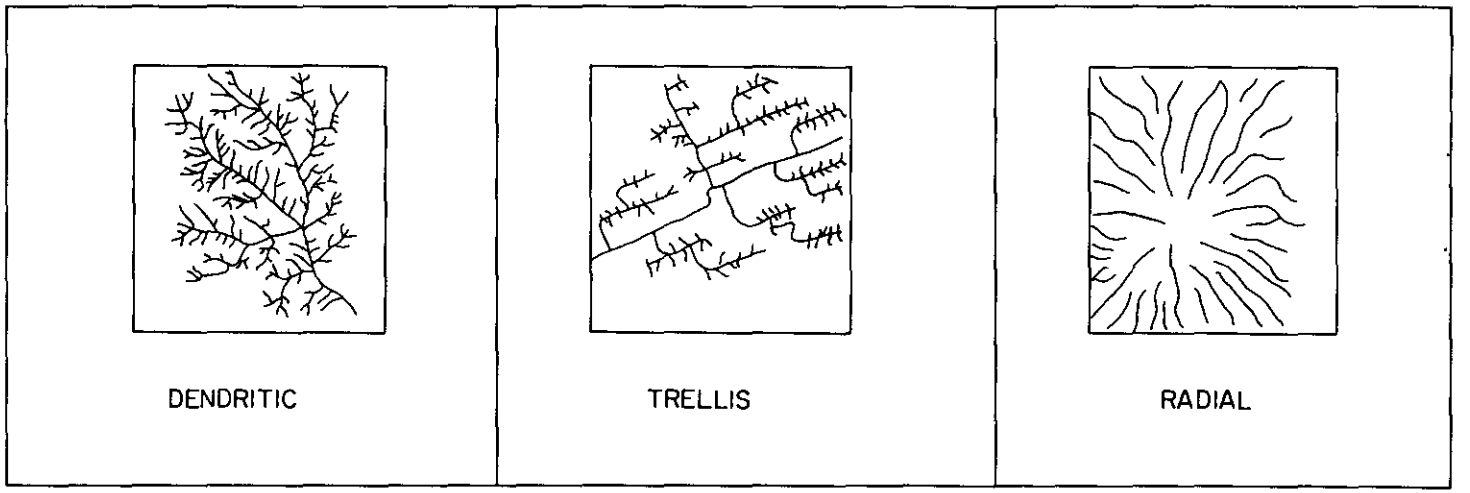

Figure 30. Drainage patterns.

in semiarid regions with seasonal rain or snowfall. Some streams are intermittent because they depend for supply upon the water table and do not have beds deep enough to be independent of fluctuations in the table.

c. Ephemeral Stream. An ephemeral stream is temporary, depending upon infrequent rainfall for supply.

d. Bottoms. Rivers and streams deepen their beds by erosion of the underlying rock. As stream erosion continues, the velocity of the current decreases, with a resulting decrease in down-cutting potential. Eventually, the cutting potential is balanced by the sediment load carried by the stream. Subsequently, unless there is a change in the topography of the catchment basin, the stream alternates between build-up and cutting down. Differences in the load carried by the water at different points, in velocity caused by changes in grade, and in the degree of hardness of the rock make the beds uneven, producing gorges, cataracts, rapids, and potholes. Where streams have a high velocity and flow over loose materials, the bottoms commonly are rocky. In slow-moving water, fine material such as silt and clay is deposited, and the bottoms will be muddy.

e. Banks. As down-cutting potential decreases, side-cutting begins and the river widens its bed or develops a curving course. As a rule, these curves will have steep banks on the outside and gentle, low banks on the inside. The conformation will vary with the composition of the bank, the velocity of the stream, and the kind of materials transported by the stream. Swift streams in rough relief commonly cut deep channels with low banks.

f. Flooding. Some streams flood annually and others infrequently. Floods may be caused by rapidly melting snow, by excessive precipitation and runoff, by ice jams, or by any combination of these. When a river is in flood, the velocity of water is greater than normal, with the fastest current in the main channel.

g. Desert Drainage. Arid climates have long dry periods with infrequent precipitation. Desert streams for this reason are irregular in volume and duration of flow. Large areas of many deserts do not have streams flowing out of their immediate vicinity because the drainage net is centralized in interior basins. There may be separate basins at different elevations in each desert. Many large streams flow into desert lakes that have no outlet, or disappear through evaporation and seepage into porous surface material. Some streams encountered in deserts originate in humid regions, flow across the arid land, and then continue their course in another adjoining humid area. When precipitation occurs in desert areas, it is likely to be in cloudbursts that generate a tremendous runoff as the water rushes down. Sheltered dry washes or wadis may become extremely dangerous locations for bivouacs, gun positions, and installations during these brief but violent floods.

64. Lakes

Some lakes are formed by glacial action creating a depression which subsequently fills with water, by the damming of a river by ice or a moraine, or by water filling a natural depression as a glacier recedes. A stream may be formed into a lake because of interference with its natural course by a lava flow, dam, or avalanche. Coastal lagoons frequently are formed by the deposition of silt or sand at the mouth of a river. The crater of an extinct volcano often collects water and becomes a lake basin. Salt lakes occur when a lake is so poorly drained that the minerals in the water remain while the water evaporates. In limestone country, lakes caused by the filling of depressions of dissolved rocks are common.

65. Marshes and Swamps

a. Description. A swamp (fig. 31) is an area of saturated ground dominated by trees and shrubs. A marsh (fig. 32) is an area of saturated ground dominated by grasslike aquatic plants. A bog is an area of soft, wet, spongy ground consisting of peat which supports mosses, low shrubs, and in some cases poorly developed trees.

b. Formation. Swamps, marshes, and bogs are formed by the overflow of rivers, dams, flooding by tides, a lack of balance between rainfall and runoff or seepage, impervious subsoil in level areas, or the spread of vegetation in lakes, particularly in oxbow lakes. They may

Figure 31. Swamp (Okefenokee Refuge, Georgia).

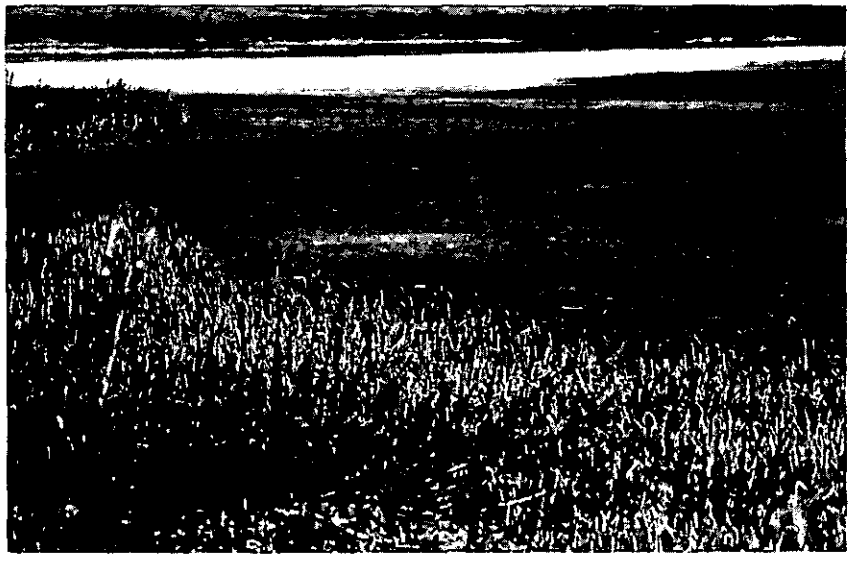

Figure 32. Marsh (Foxholm, North Dakota).

be numerous on delta and flood plains, where surface water is not readily drained. Extensive marshes and swamps are encountered on the plains of humid areas. In glaciated regions, marshes, bogs, and swamps are common.

66. Glaciers

a. Description. A glacier is a thick mass of ice that moves slowly on a land surface. Glaciers depend on the receipt of an annual amount of snow, and form only where there is a carryover of snow from one season to the next. Abundant precipitation is more important than extreme cold. The ice is formed by the crushing of snow flakes from the weight of new snowfalls and shortly altered to a loose aggregate of rounded

granules of ice. With deeper burial these granules are deformed, locally melted and refrozen and recrystallized, to produce a solid mass of interlocking ice crystals. There are two types of glaciers: *valley glaciers* and *continental glaciers.*

b. Valley Glacier. A valley glacier (fig. 33) begins in the summit areas of the high mountains. Patches of snow are converted into icefields. Those icefields at the heads of former stream valleys may eventually become thick enough so that the ice begins to move downward following pre-existing stream valleys. As the glacier moves down the valley, rock fragments become plucked from the walls and become frozen tightly in the sides and bottom of the ice. These fragments abrade the walls like a giant rasp. This abrasion scratches and polishes the walls and straightens out the valley by grinding away irregularities on opposite sides. Narrow "V" stream valleys are reamed out into much more even "U" shaped valleys.

c. Ice Front. The lower end of a glacier, or the ice front, stands at that point where the supply of ice from up the valley is just equal to the loss through melting and evaporation. If supply is greater than loss, the ice front moves down the valley; if loss exceeds supply, the ice front retreats.

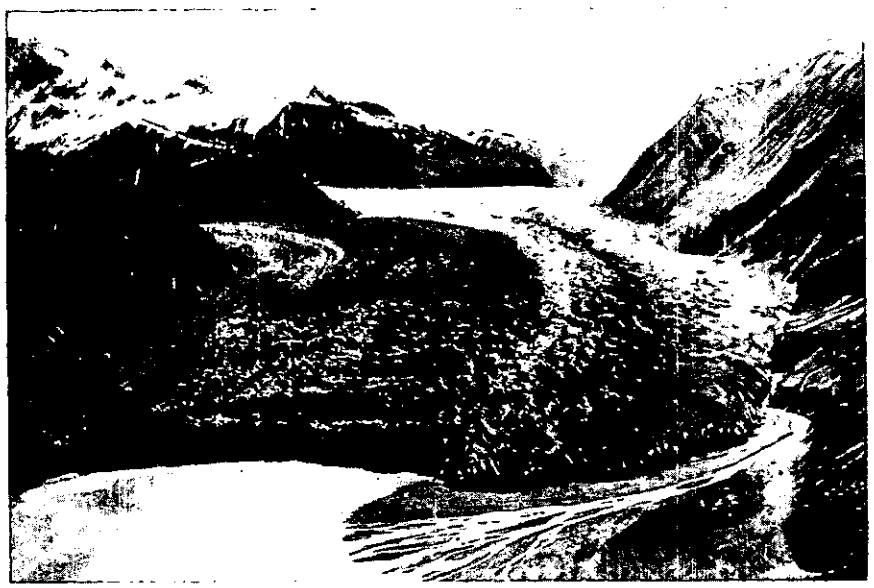

Figure 33. Valley glacier (Alaskan coast. Kame terrace and outwash plain in right foreground).

d. Debris. Rock debris carried in or on the glacier may be dumped at the ice front when the ice melts. This material, called *till,* consists of an unsorted mixture of rock powder, pebbles, cobblestone, and boulders. If the ice front remains stationary for a period of time, a ridge of till, extending across the valley, is formed. This ridge is termed an *end moraine.*

e. Continental Glaciers. Continental glaciers, such as those covering most of Greenland and Antarctica, begin in one or more central areas of snow accumulation. The ice starts to move outward when it becomes so thick that the pull of gravity on the mass exceeds the strength of the ice. No slope is required and in many cases the centers of accumulation lie at low elevations. Continental glaciers make extensive deposits dumped directly from the ice. End moraines mark positions at which the glacier edge stood for some time. They are long ridges or belts of low hills that extend across the country for many miles. Large areas on the glaciated side of the end moraines commonly receive a sheet of till plastered on the underlying rock. This *ground moraine* or *till sheet* was left behind as the heavily loaded ice sheet melted away.

f. Meltwater. Streams of meltwater leaving an ice sheet may flow down valleys that lead away from the glacial front. The material pre-

viously left from frozen ice is deposited along the stream valleys in the form of *valley trains*. Where the land surface slopes evenly away from the edge of the ice sheet, meltwater streams may spread over the countryside in branching, braided patterns forming widespread *outwash plains*. Outwash plains are composed of relatively well-sorted, evenly bedded sand and gravel which may be many feet thick and cover many square miles.

67. Ground Water

a. Hydrologic Cycle (fig. 34). Water evaporated from the ocean is condensed into clouds, from which it falls to the earth as rain, snow, sleet, or hail. Part of this water runs off into lakes and streams, or is retained by the soil, passing into underlying rock formations. Moving through openings in the rocks, the water issues at the surface as springs, streams, and lakes. Ultimately all the water that is precipitated returns to the atmosphere by evaporation from water surface or from the foliage of vegetation. Some also is released from foliage by transpiration, the process by which a plant transmits water through its tissues, discharging water vapor from its foliage. Although this hydrologic cycle is irregular and may extend over a period of years, no water is lost permanently from circulation, but a stage of the cycle may be bypassed or interrupted. Rain falling upon a heavily forested area, for example, may return directly to the atmosphere by evaporation without going through other stages of the normal natural process.

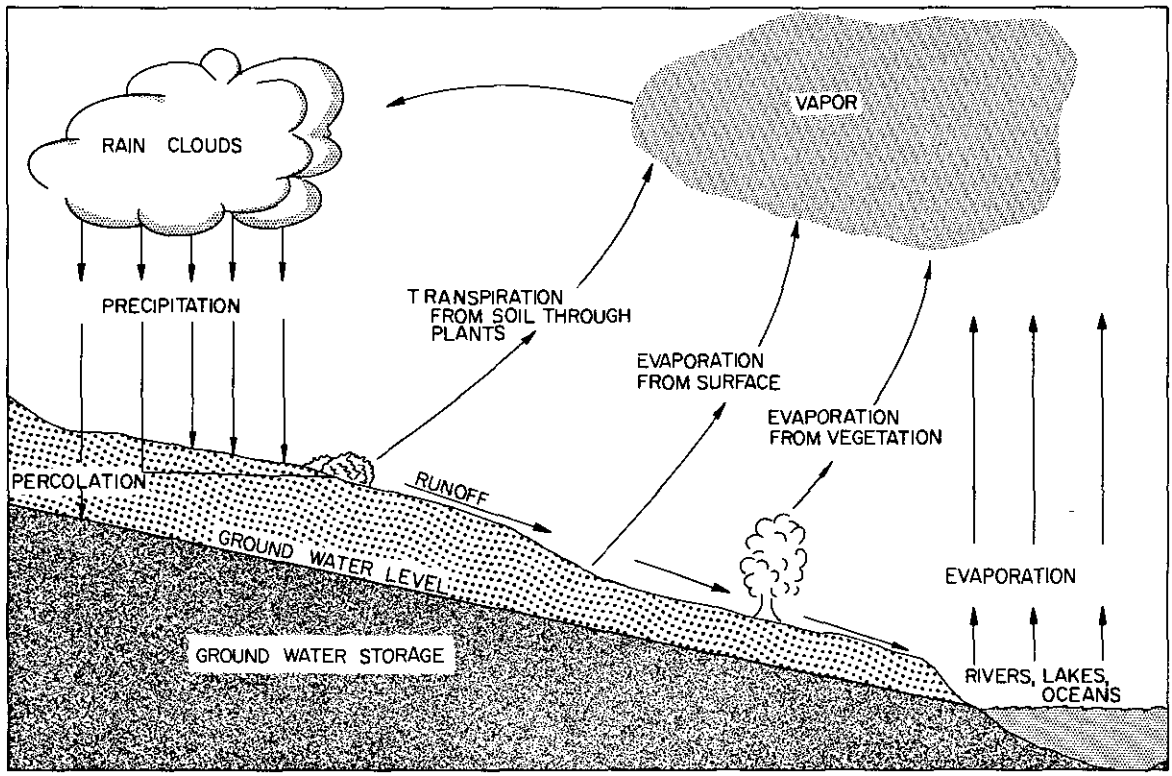

Figure 34. The hydrologic cycle.

b. Water Table. When water fills the pores and crevices of the underlying rock, a zone of saturation results. This is ground water and the top of the saturated zone is the groundwater table, or simply, the water table (fig. 35). The depth of the water table beneath the surface varies according to topography, structure of the rock formations, amount of rainfall, and nature of the pore spaces in the soil or rock. Water stored below the water table is the source of supply for springs and wells. If the water table intersects the land surface, as it may on the sides of valleys, the water will flow or seep out as gravity springs or seeps.

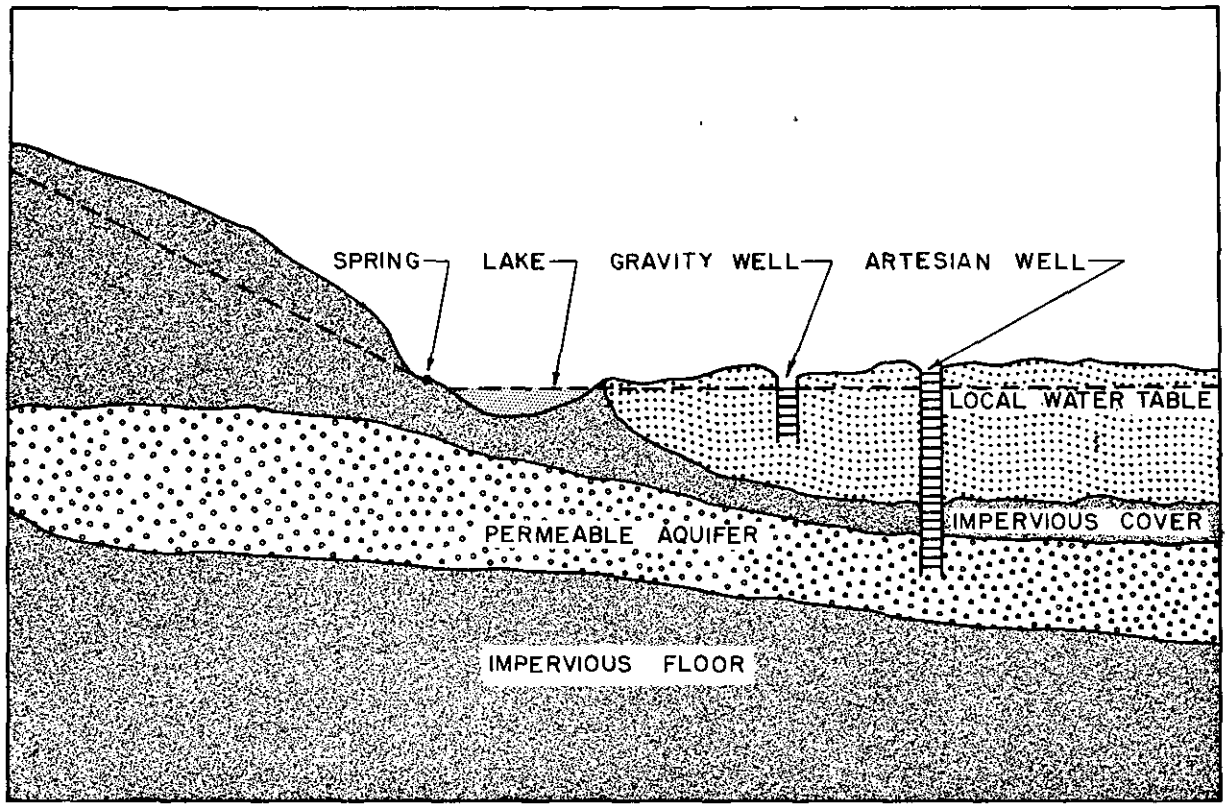

Figure 35. Water sources.

c. Springs and Seeps. Subsurface water issuing at the surface as a spring has a distinct current, flowing continuously or intermittently from a localized area. Water issuing as a seep emerges slowly over a large area, without a noticeable current. Springs and seeps are of two principal kinds; gravity and artesian.

(1) *Gravity springs.* Gravity springs and seeps are those in which the subsurface water flows by gravity from a higher point of intake to lower point of issue. This may occur where the water table comes near or intersects the surface of the ground, usually around the margins of depressions, along the slopes of valleys, and at the foot of alluvial fans. Another type occurs along an exposed contact between the overlying pervious stratum and an underlying impervious stratum. They may appear at almost any elevation along a slope.

(2) *Artesian springs.* Artesian springs occur where confined subsurface water acting under the influence of pressure from a higher water level is forced to the surface of the ground. Fissures in the rock, fault zones, and, in some cases, solution channels may serve as avenues along which water can move to the surface. The water is generally under much hydrostatic pressure, and therefore rises in the spring. Because of this rise, the spring or well is classified as artesian. A well with enough pressure to bring the water above ground is called a flowing artesian well. If the water rises only to an intermediate level, it is a nonflowing artesian well.

d. Circulation. Ground water is not static but moves slowly through openings in the rock and soil toward points of discharge. The rate of movement is controlled by gravity or hydrostatic pressure (the pressure exerted by water at a higher level) and by the capacity of the rock or soil to transmit water, termed its permeability. Climate governs the amount of

water that will be contributed to the surface. The amount that will be absorbed depends upon the amount of pore space, or the porosity of the ground.

68. Hydrological Effects on Military Operations

a. Rivers. Wide, deep rivers with valleys that offer concealment may provide good defensive areas. The employment of a river as a forward edge of battle area (FEBA), however, may also result in a frontage too wide for effective defense and with many covered areas that interfere with observation and fields of fire. Marshy terrain and ditches or tributaries interfere with lateral communications and the movement of reserves.

b. River Line. In the attack of a river line, the initial objectives are key terrain features that could permit the enemy to bring effective small-arms fire on the crossing area. Next are features that allow the enemy to deliver observed artillery fire, and, finally, those areas on the enemy side of the river that are required to accommodate the troops, equipment, and installations necessary to prevent the enemy from delivering effective sustained artillery fire. A river or stream may be a temporary obstacle to cross-country movement, but it slows down advancing forces only until it is bridged or assault boats can be brought to the site or a crossing by helicopter is effected. The effectiveness of a river as an obstacle increases with its width, depth, and velocity. Rivers more than 150 meters (500 feet) in width are major obstacles.

c. River Floods. Floods may cause long traffic interruptions particularly by damaging temporary bridges. A flood may immobilize a theater of operations unless an adequate system of stream-gaging stations and flood-warning agencies has been established for all key rivers. Streams in mountainous areas are characterized by a high velocity with considerable variation in their flow. While they may be effective obstacles during flood periods, they usually are so low in dry seasons that their beds may offer routes of approach rather than obstacles to movement. Such streams, however, are likely to have beds so rocky as to eliminate vehicular movement.

d. Lakes. Usually lakes are obstacles to movement because few are narrow enough to be bridged. They must be bypassed or crossed in amphibious vehicles or boats and where they exist in chains or large groups, as in glaciated areas, they become major obstacles (fig. 36). The narrow land corridors separating the lakes canalize troop movements and limit maneuver, rendering troops highly vulnerable to attack. A series of interconnected lakes may provide an extensive communication system and may also include navigable rivers and canals as in Finland. An ice cover that is 1 meter (3 feet) or more in thickness will support heavy loads. Roads across frozen lakes may be prepared by clearing away the snow.

Figure 36. Arctic lake region (Northwest Canada).

e. Marches and Swamps. Normally movement through a swamp or marsh is usually limited to causeways, but many vehicles are now used in swamps in what is known as a riverine operation. These may be key terrain features that could be seized by airborne, airmobile, or mechanized forces prior to a large-scale movement. Mud and peat bottoms usually prevent cross-country movement. Special engineer floating and portable bridging equipment may be necessary to supplement other means of traversing a swampy area or to cross or bypass a gap in a causeway. Snow roads may be built over swamps by removing the snow and then pouring water over the cleared surface until a frozen surface is obtained.

69. Information Requirements — Drainage

Major drainage areas are shown on maps of appropriate size accompanying some terrain studies. Textual notes are provided if the important facts cannot be shown adequately on a map. Detailed information on features of military significance along a stream or portions of it may be shown on a strip map or annotated photomosaic. Information may include—

a. Rivers and Streams.

(1) Name or other identification, and location.

(2) Channel characteristics (form (fig. 37), length, profile, gradient of stream bed).

(3) Bottom characteristics (composition, depth, firmness, unusual conditions).

(4) Flow characteristics.

(*a*) Measurements and periods of occurrence at low, high, and mean water of depth, width, volume of discharge, and velocity (minimum, maximum, and mean).

(*b*) Special phenomena (crosscurrents, undertows, eddies, floods); periods; area covered; destructive effects. Tidal effects at low, high, and mean tides.

(5) Physical and chemical characteristics of water (turbidity, color, odor, taste, temperature, chemical composition, bacterial pollution, seasonal variations).

(6) Bank characteristics (composition, stability, height, and slope).

(7) Regulatory structures (levees and dams).

(8) Islands, bars, shoals, and rapids (name, size, surface roughness, elevation, and pattern).

(9) Ice (earliest, latest, and mean freezing and breakup dates, extent of frozen surface; thickness of ice; carrying capacity; and frequency and location of ice jams).

(10) Kind and prevalence of animal and vegetable life.

(11) Type and location of crossings.

(12) Utilization of watercourse (for water supply, irrigation, disposal of waste).

(13) Accessibility for military water supply (relation of road nets to potential water points, off-road approaches, intake problems).

b. Lakes.

(1) Name or other identification, and location.

(2) Length, width, depth and surface area at low, high, and mean water; periods of occurrence of each.

(3) Gage locations and periods of record, zero gage elevations, mean and extreme gage heights and periods of occurrence.

(4) Shore characteristics (composition, stability, height, and slope).

(5) Physical and chemical characteristics of water (turbidity, color, odor, taste, temperature, chemical composition, bacterial pollution, seasonal variation).

(6) Bottom characteristics (composition, depth, and firmness of material, unusual bottom conditions, profiles).

(7) Regulatory structures.

(8) Islands, bars, and shoals (name, size, surface roughness, elevation, and pattern).

Figure 37. Characteristic braided stream drainage pattern (Canada).

(9) Ice (earliest, latest and mean freezing and breakup dates; extent of frozen surface; type and thickness of ice; and carrying capacity).

(10) Kind and prevalence of animal and vegetable life.

(11) Type and location of crossings.

(12) Utilization of water body (for water supply, irrigation, disposal of waste).

(13) Accessibility for military water supply (relation of road nets to potential water points, off-road approaches intake problems).

c. Marshes and Swamps.

(1) Information in *b* above, as applicable.

(2) Seasonal variations (months when variations in extent and wetness are greatest and least).

(3) Cross-country movement under various seasonal conditions.

(4) Existing or potential causeways.

(5) Special conditions (quicksand, permafrost).

Section IV. NEARSHORE OCEANOGRAPHY

70. Beaches

a. Description. A beach is defined as the area extending from the shoreline inland to a marked change in physiographic form or material, or to the line of permanent vegetation (coastline). In amphibious operations, it is considered that portion of the shoreline designated for landing a tactical organization. Beaches are characterized according to their predominant surface material, such as sand, silt, cobble, pebble, boulder, or by combinations of these materials, such as sand and pebble. Mud beaches are common, but silt is not usually found in beach form, occurring more commonly in underwater banks and shoals. In general, beaches are long and continuous on low-lying coasts, or on shores with soft rock formations, and where there is an abundant supply of material deposited by streams. Along hard-rock coasts and on those not well supplied with stream-carried material, beaches are short and discontinuous, and are usually separated by bold headlands or rock outcrops (fig. 38).

b. Width. The width of a beach is subject to considerable change. Where there are seasonal variations in wave attack and the supply of material, beaches may disappear or be greatly damaged when the wave attack is heaviest. Beaches formed principally by streams usually show marked seasonal variations in width, and are widest during the period of least rainfall. Beach widths are most nearly constant when the beaches are protected by groins or similar structures.

Figure 38. Characteristic coastline, hard-rock terrain (Brazil).

c. Slope. The slope of a beach is determined chiefly by the size of the beach material and the intensity of wave attack. Beaches of fine sand that are not subject to intense wave action commonly have slopes ranging from 1 on 5 to 1 on 60. Coarse material under light wave attack results in beach slopes from 1 on 5 to 1 on 10. The band of wave uprush on a beach is a good indication of the slope. On air photographs it may appear as a dark band lying just landward of the waterline. A wide uprush band indicates a flatter slope than a narrow band. On gravel beaches, however, uprush bands are always narrow, and usually do not appear clearly on aerial photographs.

d. Firmness. There is a wide variation in firmness between different beaches and different parts of the same beach. Beaches are most firm when damp and when the material size is small. Dry sand usually is soft, except when the material size is small. Pebble, cobble, and boulder beaches are firm as far as bearing strength is concerned but are loose, making it difficult for tracked vehicles to cross them. Silt and clay are invariably soft, but combinations of mud and sand provide a hard surface. As a rule, exposed beaches are firmer than similar beaches in sheltered locations.

e. Vegetation. Vegetation immediately in rear of a beach is an indication of stability. Such areas are firmer than other parts of the beach and always lie above the limit of wave uprush. There is no vegetation on gravel beaches, but beaches composed of gravel and sand in combination may have a vegetation cover.

f. Assault Landing. Assault landing is based upon the potential of the beach and hinterland to permit the initial landing and the logistical support for the operation. Attack transport ships (APA) and attack cargo ships (AKA), which have a loaded draft of 8 meters (27 ft) and 7.3 meters (24 ft), respectively, require landing crafts for unloading. A landing ship tank (LST) requires a maximum draft of 4 meters (13 ft), a landing craft medium (LCM) 1.5 meters (5 ft), and a landing craft, utility (LCU) 2 meters (6.5 ft). Additional aid in landing supplies and personnel include mobile pier sites such as the Spud Barge pier, bridging and engineer equipment required to prepare the terrain for landing.

g. Fresh Water. Fresh water is seldom available on undeveloped beaches, although it may be obtained from nearby streams or in completely inclosed pools or lagoons that lie immediately behind the beach. Streams or rivers with steep gradients that cross the beach will provide fresh water at sites above the highest reach of the tide.

71. Terrain Adjacent to Beaches

a. Ridges. Beach ridges are mounds of beach material heaped up by wave action along the upper limit of wave uprush as single ridges or as a series of approximately parallel ridges extending some distance inland. Commonly these ridges reach from 1 to 2.5 meters (3 to 8 feet) above mean high tide, but individual ridges may be as high as 9 meters (30 feet). High ridges are found only in exposed locations, and are signs of occasionally severe storm wave action. Ridges occur only when there is an abundant supply of material on or in back of the beach. In some locations belts of beach ridges extend for 2 or 3 kilometers (a mile or two) inland, with a vertical difference in elevation of only a meter (few feet). Usually these areas are covered with grass or low bushes.

b. Dunes. Dunes are formed by windblown sand carried inland from the beach and deposited as irregular hills or mounds. The sand is of fine to medium size. Dunes may reach heights of 90 meters (300 feet), although commonly they do not exceed 30 meters (100 feet) in height. Where there is vegetation, low bushes, and grass the dunes are fairly firm and can be crossed by light vehicles. Fresh water may be obtained from wells sunk in depression between dunes (fig. 39).

72. Underwater Topography

a. Description. An examination of the terrain as shown in photographs, topographic maps, and hydrographic charts will indicate the probable characteristics of the hydrography. If the land behind the beach is flat and sandy or marshy, the sea bottom close inshore also will be fairly flat. A beach located on a long stretch of regular coastline normally will have one or more sandbars offshore. Large rock outcrops along the beach or close inland indicate that there are probably similar outcrops under-

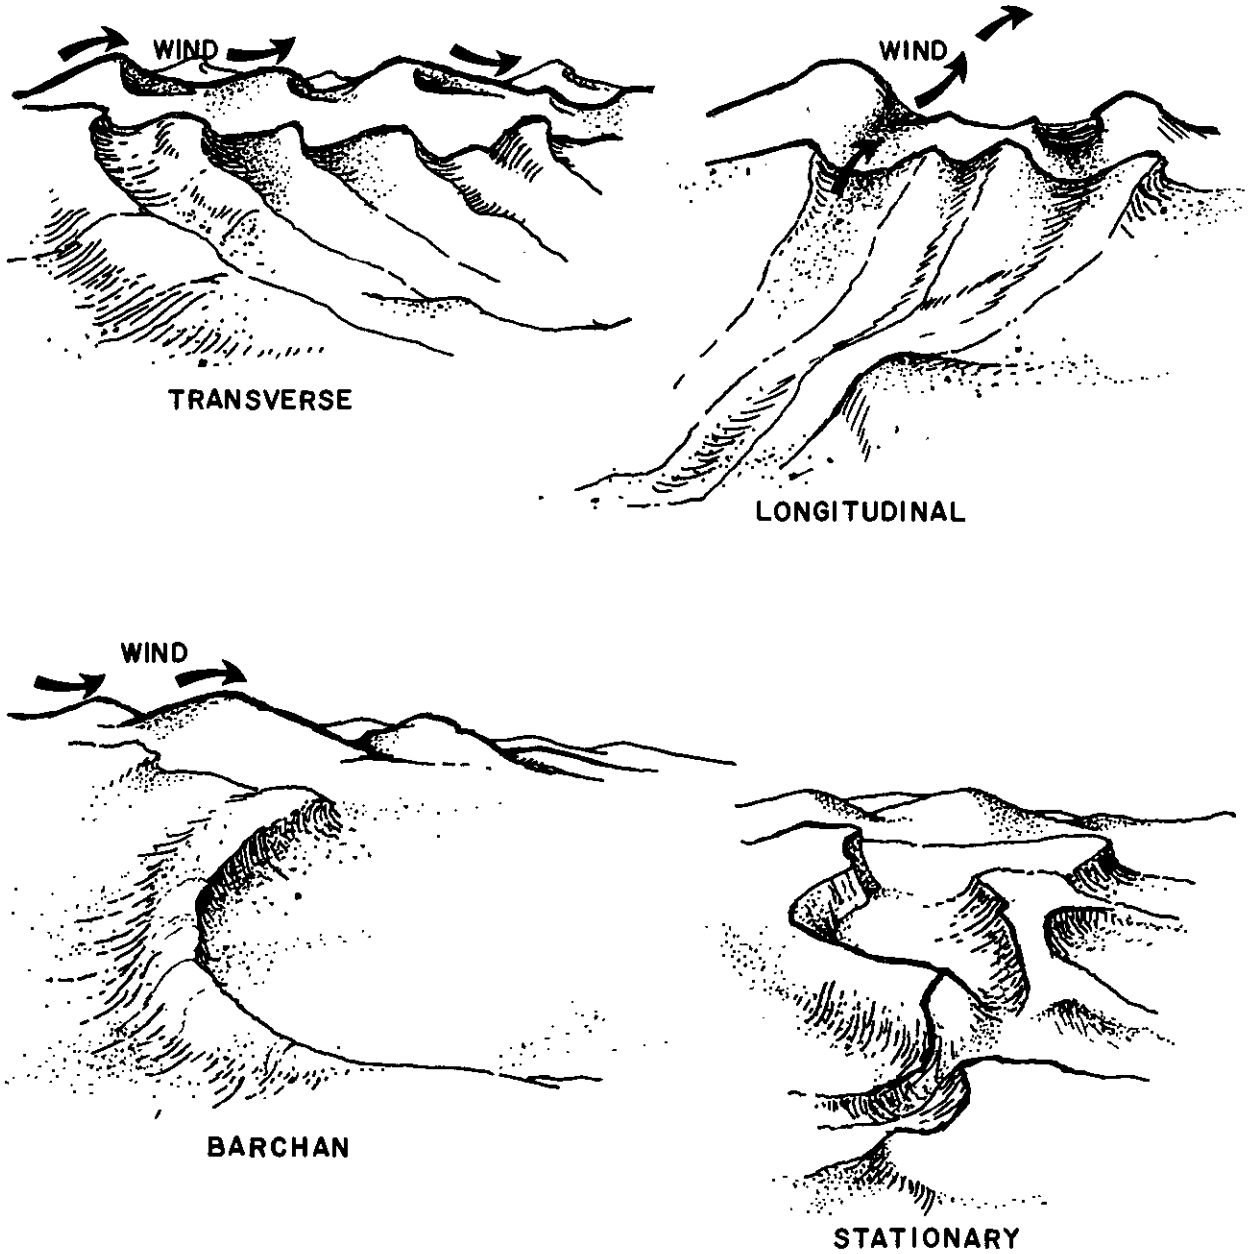

Figure 39. Windblown stationary dunes.

water near the shore. Beaches backed by cliffs or steeply rising hills generally will have a fairly steep underwater gradient. The form of the beach also indicates the underwater contours. A wide, flat beach is an indication of a gently sloping bottom offshore, and a sharp narrow beach suggests a steep slope. Sand beaches have flat to steep slopes, and beaches of gravel, cobble, or boulders are usually steep. It must be remembered, however, that the entire beach profile is changeable, varying with the wave conditions that act upon it. Short concave or pocket beaches (fig. 40) flanked by well-developed headlands are the most constant in their form.

b. Bottoms. The characteristics of the materials that comprise the nearshore bottom are significant in relation to their suitability for the movement of men, vehicles, and landing craft. Bearing strength and smoothness of grad-

Figure 40. Concave beach.

uations are the most important factors. Sand, sand and shell, and gravel bottoms are ideal for landing operations. They are firm and usually quite smooth, although bank, bar, and shoal formations are common. Sand and mud mixtures may be either firm or soft, but they usually are smooth. Mixtures with a high percentage of sand are firm, the firmness decreasing as the sand content is reduced. This type of bottom often has soft spots that may prove hazardous. Mud bottoms are generally avoided, since they are soft, smooth, and slippery. An exception is the case of a thin mud cover overlying a rock bottom, where the rock provides an underlying formation that will give a satisfactory bearing surface if the mud is not more than a meter thick. Clay bottoms are unsatisfactory, since they are soft and slippery and have little strength.

73. Coral Reefs

a. Description. Reef-building corals are marine animals that remove lime from sea water and deposit it around their living bodies, making hard structures of many types. They do not flourish at temperatures much under 75° F. Consequently coral reefs are found only in tropical waters. Since corals cannot move, securing microscopic food from water moving around them, they are usually found near the edge of reefs, along channels, and out from headlands. They cannot form opposite muddy streams or those with a heavy discharge. If the water movement in coral areas is swift enough, rounded coral heads will predominate, and in more quiet water there usually is an open growth of branching corals. Reef corals cannot stand exposure to the air for more than a few hours, so that their upward growth is limited by the level of mean low water. They belong to one of three types—fringing reefs, barrier reefs, or atoll reefs (fig. 41).

b. Fringing. A fringing reef is attached to the shore. If the wave attack is weak, there will be a gently sloping beach of coral sand. Strong wave attack results in steep gravel, cobble, and boulder beaches. On most fringing reefs there are boat channels about 0.3 to 4.5 meters (1 to 15 feet) deeper than the rest of the reef-flat, from 10 to 45 meters (10 to 50 yards) or more wide, and more than a mile in length. These run approximately parallel to the land, opening into breaks in the reef, and providing convenient waterways for small craft.

c. Barriers. Barrier reefs are located roughly parallel to the coastline at some distance offshore. Whether or not a craft can cross a barrier reef depends upon the depth of the coral below water. Usually the coral surface is about 15 centimeters (6 inches) above mean low water, but it may be deeper. Walking upon the reef is dangerous, since the reef-flat is seldom above water and the holes between coral colonies are irregularly spaced, deep, and lined by jagged coral. At low water, extensions of the reef into the lagoon behind it may create compartments that hinder or prevent the free movement of craft along the reef.

d. Atoll. Atoll reefs (fig. 42) are more or

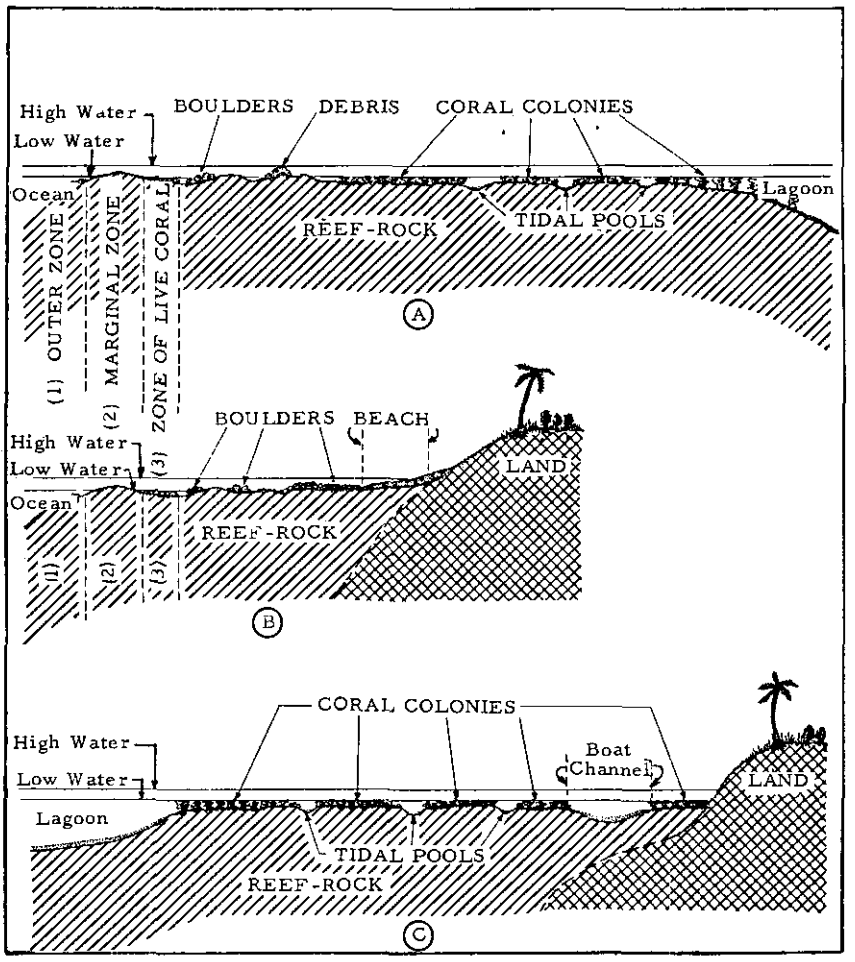

Figure 41. Barrier and fringing reefs—diagrammatic cross-sections.
(A) Wide barrier reef.
(B) Narrow exposed fringing reef.
(C) Protected fringing reef. (Not drawn to scale.)

less rings of coral inclosing circular lagoons. The marginal zone of the reef is a strip from 25 to 70 meters (25 to 75 yards) wide, across which a belt of surf moves with the rise and fall of the tide. If the outer, seaward slope of the reef is steep, there is a clear approach for landing craft. A gentle slope will have coral heads growing just outside, making an approach dangerous. At high tide it may be possible to cross the marginal zone by boat. Reef islands usually are located on higher parts of an atoll reef. Typically these islands are surrounded or partly surrounded by a beach 3 to 15 meters (10 to 50 feet) or more wide, consisting of coral sand and organic debris. Reef islands are seldom more than 3 to 4.5 meters (10 to 15 feet) higher than the reef-flat, and their interiors usually are flat and featureless. From the viewpoint of landing operations, the most unfavorable feature is the high, surf-covered marginal zone. Surf intensity is less on the leeward side. On the lagoon side by entering through channels or breaks in the reef, craft may land on the sand beach at high water. Crossing the reef-flat at low tide is impracticable.

74. Military Considerations

a. Coastlines. A concave coastline is formed by a projection of water (bay or gulf) extending into the coast. From the flanks, converging fires may be brought upon landing forces. The convex type of shoreline includes gently outcurving shores, points, capes, and peninsulas. Supporting fires may be placed on the defender

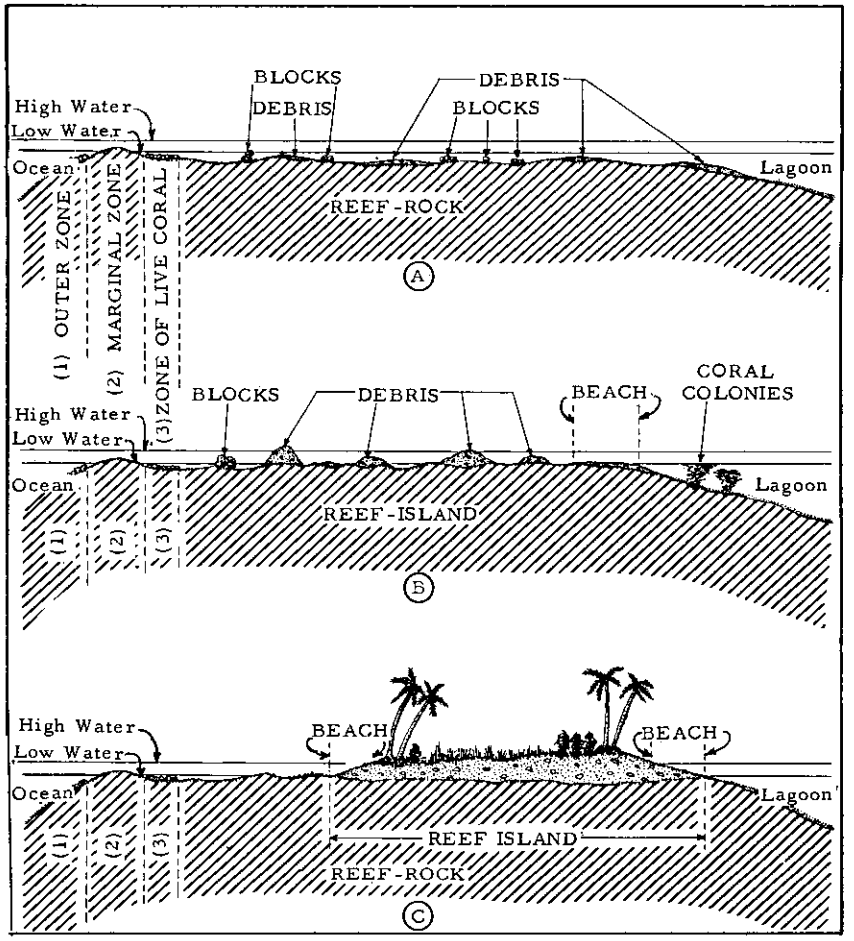

Figure 42. Atoll reefs—diagrammatic cross section.
(A) Open reef area.
(B) Area of impermanent debris accumulation.
(C) Reef-island area. (Not drawn to scale.)

from his flanks and, occasionally, from his rear. His routes of withdrawal or reinforcement are restricted. It is difficult for the defender to organize his fires and to secure extensive fields of fire. Convex shorelines are more exposed to currents, winds, and surf and are often steep and rocky, making landing difficult. A straight shoreline has no prominent indentations or promontories. It offers no decisive advantage either in attack or defense. Very few coastlines, however, are so straight that provide no positions for flanking fires. An irregular coastline is a complex of concave and convex shorelines.

b. Reefs. Barrier and atoll reefs may be obstacles at a distance from the landing beach. A fringing reef forms a nearshore obstacle, normally with a rough tablelike surface, that extends seaward from the shoreline at a level slightly above or below the water. A wide fringing reef provides an area well suited to the organization of defensive smallarms fires.

c. Offshore Islands. Frequently shorelines are protected by groups of small islands lying so close to the mainland that they form a complicated system of waterways immediately offshore. Routes of approach to the mainland through the islands may be tortuous and restricted, making an approaching landing force highly vulnerable throughout its shoreward movement. These islands may be neutralized with nuclear weapons or may be isolated and reduced in detail by successive minor landings preceding the main amphibious attack. Once

secured, they provide the attacker with favorable artillery positions to support the landing.

75. Information Requirements — Landing Areas

Terrain studies made for planning amphibious operations are very detailed. Normally they are based upon the complete data that is provided by special studies and major sources. In general, the following items represent the fundamental information requirements relative to a proposed landing area:

a. Location.

(1) For a beach 3 kilometers (2 miles) or more in length, the latitude and longitude of its limits; for a beach less than 3 kilometers (2 miles) long, the center of the landing area is given.

(2) Nearness to objective of the operations, if known, and to developed areas such as water terminals, harbors, and adjacent beaches.

b. Sea Approach.

(1) Landmarks, both natural and man-made.

(2) Hydrography (nearshore and offshore depths; flats (tidal or other), character of the material and its bearing strength; length of and depths over reefs, bars, shoals, or other natural obstructions; anchorage areas and their conditions; character of nearshore bottom material).

(3) Tides and currents (tidal rise and fall, local peculiarities, direction and magnitudes of currents; neaps and springs).

(4) Winds (strength, direction, effect on tidal heights and surf, local peculiarities).

(5) Waves and surf (height and period of offshore waves; intensity).

c. Beach.

(1) Material (type and size, firmness, variability with weather or season, subsurface material).

(2) Gradient (note particularly scarps and ledges).

(3) Beach structures (groins, bulkheads, jetties, submerged remains of former structures).

(4) Rivers and streams (variability in beach character where rivers cross beach; river channels).

(5) Effects of weather and duration of darkness and daylight.

(6) Local use of beach.

(7) Sources of fresh water on or near beach (both potable and nonpotable).

d. Terrain Inland or on Flanks.

(1) Topography (topographic features, waterways, swamps or marshes, vegetation, location and size of possible dump or assembly areas).

(2) Exits (existing exits by roads or trails; cross-country exits; roads, with details of width, surface, construction; railways, tramways).

(3) Aircraft landing sites within a 16- to 24-kilometer (10- to 15-mile) distance from beach (dimensions, surface, topography).

(4) Utilities (communications, electricity, water supply, transportation).

(5) Helicopter landing sites.

Section V. SURFACE MATERIALS

76. Types of Soils

a. Composition. Soil is defined as the unconsolidated material that overlies bedrock. Soil is made of disintegrated rock, in the form of sand or clay, and humus, the disintegrated remains of past vegetation. Detailed information about soils, their engineering properties, and testing techniques is contained in TM 5—541. Some essentials of soils trafficability are given in chapter 9. For field identification and classification, soils may be grouped into five principal types: gravel, sand, silt, clay,

and organic matter. These types seldom exist separately but are found in mixtures of various proportions, each type contributing its characteristics to the mixture.

b. Gravel. Gravel consists of angular to rounded, bulky mineral particles ranging in size from about 0.6 to 8 centimeters (¼ inch to 3 inches) in diameter. It is classified as coarse or fine; well or poorly graded; and angular, flat, or rounded. Next to solid bedrock, well-graded and compacted gravel is the most stable natural foundation material. Gravel is easy to drain, easy to compact when well graded, affected little by moisture, and not subject to frost action.

c. Sand. Sand consists of mineral grains ranging from about 6 millimeters (¼ inch) down to about 0.08 millimeters (.003 inch) in diameter. It is classified according to size and gradation as coarse, medium, or fine; and as being angular or rounded. Well-graded angular sand is desirable for concrete aggregate and for foundation material. It is easy to drain, little affected by moisture, and ordinarily not by frost action. Sand provides an excellent road subgrade material when it is confined. Care is required, however, to distinguish between a fine sand and silt.

d. Silt. Silt consists of natural mineral grains ranging from about 0.08 millimeters (.603 inch) to about .005 millimeters (.0002 inch) in diameter. It lacks plasticity and possesses little or no cohesion when dry. The term rock flour is commonly used to describe inorganic silts of glacial origin. All silts are treacherous for trafficability and as a foundation material. Because of its inherent instability, slight disturbances in the presence of water, such as traffic vibrations transmitted to a wet silt subgrade, will cause the silt to become soft or to change to a "quick" condition. When ground water or seepage is present, silts exposed to frost action are subject to intensive ice accumulation and consequent heaving. Silts are difficult to compact and drain.

e. Clay. Clay generally consists of particles smaller than 0.005 millimeters (.0002 inch), microscopic in size. Its plasticity and adhesiveness are outstanding characteristics. Depending upon the proportion of coarser grains, clays vary from lean clays (low plasticity) to fat clays (high plasticity). Many clays which are brittle or stiff in their undisturbed state become soft and plastic upon being worked.

77. Soil Maps

a. Contents. Soil maps or overlays indicate the predominant soils in given areas, identifying them according to their engineering characteristics. Such maps may be constructed from air photographs or ground reconnaissance or made from existing soil and geologic maps and reports with the classifications expressed in engineering terms. Agricultural soil maps can be large enough to provide detail for tactical planning, but often the designated soil type applies only to the surface soil. These maps should indicate the following properties of soils:

(1) Permeability.

(2) Stability under stress.

(3) Bearing capacity.

(4) Important variations of (2) and (3) above with changing moisture content.

b. Coverage. For strategical planning, soil maps should cover the area of the study. A large amount of general information may be presented, because detailed plans may not be firm and the future weather conditions uncertain. The information includes the effects of weather upon the soils. The reliability of the information must be clearly indicated.

c. Planning. Soil maps for tactical planning cover a smaller area than do strategical soil maps. They are of a larger scale and contain more precise, detailed information. Greater accuracy is possible because more details are known about the proposed operations. Reconnaissance and patrol reports make it possible to check the ground, and weather forecasts are available to indicate what the prevailing weather will be. The information contained on such maps is useful in determining—

(1) Areas critical to cross-country movement as they affect both advances and counterattacks.

(2) Stretches of road liable to failure under heavy traffic.

(3) Suitable and unsuitable areas for airfields, field fortifications, and other installations.

(4) Areas with soil conditions that are unsuitable for tank and vehicle parks.

(5) Difficult areas for field and air defense artillery deployment.

(6) River bank conditions for bridge foundations and crossing operations.

d. Rear Areas. In planning rear area activities, soil maps are useful for determining road conditions. In order to stand up under heavy traffic during periods of frost and thaw, a road must have a well-drained subsoil foundation. A knowledge of the soils in an area will reveal which stretches of road will be most susceptible to breakdown during a thaw, providing a guide to selecting the best supply routes and indicating portions of the road where precautions must be observed. When supplemented by an aerial reconnaissance, soil maps are a valuable aid in highway location and relocation. They indicate the soil areas with desirable or undesirable engineering characteristics and also show the nearest sources of materials for road construction and maintenance. The information about soil conditions given by a soil map is invaluable in selecting sites for airfields, storage installations, ammunition dumps, and vehicle parks. Preliminary study of the map prevents unnecessary field reconnaissance.

78. Military Aspects of Soils

a. Weather. The actual identity of the type of soil in any area is of little practical value unless the soil is also evaluated in relation to the existing or predicted weather. In general, the major soil types have the following characteristics:

b. Gravel. Weather has little or no effect on the trafficability of a gravel soil which is excellent for tracked vehicles. It it is not mixed with other soil, however, the loose particles may roll under pressure, hampering the movement of wheeled vehicles.

c. Sand. When wet enough to become compacted, or when mixed with clay, sand gives excellent trafficability. Very dry, soft, or loose sand is an obstacle to vehicles, particularly on slopes.

d. Silt. When dry, silt provides excellent trafficability, although it is very dusty. Silt absorbs water quickly and turns to a deep, soft mud when wet, imposing a definite obstacle to movement. It dries quickly after a rain, soon becoming trafficable again.

e. Clay. When thoroughly dry, clay provides a hard surface with excellent trafficability, but it is seldom dry except in arid climates. Although clay absorbs water very slowly during a rain, it also takes a long time to dry. Wet clay is very sticky and slippery. Slopes with a clay surface are difficult or impassable, and deep ruts form rapidly on level ground. A combination of silt and clay makes a particularly poor surface when wet.

f. Special Soil Conditions. If a soil has underlying bedrock near the surface, it will become thoroughly saturated after a rain. The water cannot drain away, making the surface untrafficable.

g. Manmade Effects. Soil under cultivation because it has been worked is softer and absorbs water more quickly than other soils and may therefore have poorer trafficability. Usually the presence of irrigation structures indicates that the soil is soft and contains water and the soil generally will have poor trafficability. The types of crops cultivated in an area provide indications as to the nature of the soil. Since gravelly soils are especially suitable for fruit orchards, for example, the presence of extensive orchards, especially on flat areas, may indicate that the soil has a high gravel content. Many cultivated plants have specific soil and water requirements, giving a clue to the soil and drainage of the area.

h. Nuclear Weapons. Soil composition and density affect the amount of damage by shock that will result from a surface or subsurface burst. Propagation of the shock wave is poorest in light, loamy soils and best in plastic, wet clay. The pressures transmitted by the blast may be 50 times greater than those transmitted through sandy clay. The size and shapes of craters produced by a surface or subsurface burst, their effectiveness as obstacles and the

intensity and decay rate of induced radiation in the soil are also affected by the soil composition and density.

79. Information Requirements—Soils

In a terrain study, soil information usually is presented in tabular form, with the data keyed to a soil map or overlay. It covers—

a. Extent of each dominant soil type.

b. Depth of each type in areas indicated.

c. Surface texture (fine or coarse).

d. Parent material.

e. Description of material.

f. Properties when wet, dry, or frozen, including suitability for specified military vehicles under various conditions, bearing capacity for structure foundations, and permeability when wet.

g. Variations from dominant soil type in specified areas.

h. Areas of permafrost, permanent ice and snow.

i. Seasonal state of the ground (dry, wet, flooded, frozen, snowcovered) by seasons, months, or shorter periods. Effects of each state on cross-country movement, construction, excavation, cover and concealment, and other military aspects.

80. Rock

a. Classification. Rock may be defined as the firm and coherent or consolidated material of the earth's crust. Bedrock is solid undisturbed rock either exposed at the surface or underlying the soil. Igneous rock is formed by cooling and solidification from a molten or partly molten state; sedimentary rock, from material accumulated as a deposit from water or the air, and metamorphic rock, by the recrystallization of igneous or sedimentary rock under the influence of heat, pressure, or both. The information, characteristics, and uses of rock are explained in TM 5–545.

b. Underground Installations. Underground installations require rock and soil that are easily worked and locations that are accessible to transportation and power facilities. Plains, terraces, and alluvial fans usually are best for bunker type installations. The most favorable terrain for tunnels normally is found on plateaus, escarpments, high hills, and mountains with steep bare-rock surfaces. Large bunkers require deep, well-drained soils, with the water table at least 4.5 to 6 meters (15 to 20 feet) below the surface. They should be protected against surface-water flooding, especially if they are located on low plains. Military tunnels may be constructed for tactical, communication, storage, and shelter purposes, including—

(1) Undermining of enemy positions and countermining.

(2) Galleries for water supply.

(3) Fortifications (headquarters, gun emplacement, ammunition storage, defensive installations).

(4) Underground factories and hangars.

c. Tunneling.

(1) *Construction.* Before tunneling operations are initiated, a geologist should evaluate the proposed site. Tunnel type installations are favored by high, steep slopes of exposed bedrock. The tunnel is kept dry by placing the lowest levels above the water table and by constructing it in rocks that have a minimum of fissures, joints, and faults that would permit seepage and flooding. The size of the chambers depends upon the stability of the rock. The thickness of natural cover required to give adequate protection depends upon the type of rock and soil, degree of soundness of the rock, absence of joints and fissures, and the size and shape of the underground openings.

(2) *New methods.* In Viet Nam extensive hand-dug tunnels and tunnel complexes have been found. They are used as hiding places, caches for food and weapons, headquarters, and protection against air attack and artillery fire. They have concealed entrances and exits, camouflaged bunk-

ers, trap doors, and dead ends to confuse the attacker. One trap door may lead to a short change-of-direction tunnel and another door to a second change of direction, and a third door to the main tunnel. There are also multilevel complexes with storage and hiding rooms at lower levels. Some of these have air or water locks as "firewalls" to prevent blast, fragments, gas or smoke from passing from one section to another. The entrances are camouflaged and booby-trapped.

81. Information Requirements—Rock

Terrain studies of an area will be concerned chiefly with the availability of unexploited natural deposits suitable for the construction of roads, protective works, airfields, and underground shelters. The particular information that will be required depends upon the purpose of the study. Requirements may include—

a. Rock Deposits.

(1) Location and extent of deposit.

(2) Type and properties of the material.

(3) Suitability for construction use (as aggregate, binder, surfacing, ballast, riprap, masonry construction material).

(4) Accessibility.

b. Underground Shelters.

(1) Existing areas (mines, caves, underground manmade installations). Characteristics. Special constructions.

(2) Areas suitable for development (rock structure, comparative advantages and disadvantages of indicated locations).

Section VI. VEGETATION

82. Broad Classification of Plants

Vegetation may be classified in four broad categories—trees, shrubs, grasses, and cultivated vegetation. The type of vegetation in an area gives an indication of the climatic conditions, soil type, drainage, and water supply. Seasonal seepage or a rise in the ground-water supply often is indicated by vegetation such as reeds, sedges, cottonwoods, and willows, which thrive wherever seepage occurs. Similarly, arid conditions are also indicated by characteristic desert vegetation. TM 5-545 describes the indications typical of various plant species.

83. Trees

a. Definitions. Trees are defined as perennial woody plants at least 10 feet in height, with single stems and definite crown shapes. A forest is an extensive area covered by trees growing in a close formation, so close that in most cases their crowns touch. Smaller areas covered by trees may be termed woods, groves, or woodlots. In the terminology used on U.S. Army maps, any perennial vegetation high enough to conceal troops or thick enough to be a serious obstacle to free passage is classified as woods or brushwood. Commonly, a deep woods is considered as one that is large enough to provide ample concealed maneuver space for large units deployed in depth. This would include a woods that would conceal both the assault and reserve echelons of a brigade in the attack. A shallow woods is one that is not large enough to conceal elements of this size. Dense woods are those where the growth is thick enough to interfere with visibility sufficiently to limit the maneuver of troops.

b. Characteristics. In temperate regions, trees are commonly found at elevations of not more than 2,440 meters (8,000 feet) above sea level. A good forest climate is one with a warm, rainy vegetative season, a continually moist subsoil, and low wind velocity. The growth of trees is greatly influenced by the temperature of the air and soil; even the hardiest conifers require a mean warm month temperature of at least 50° F.

c. Classification. Trees are classified as either deciduous or evergreen (fig. 43). Deciduous trees drop all their leaves seasonally, but evergreen trees retain their leaves throughout the

year. Trees are also either needleleaf or broadleaf. In the middle latitudes, needleleaf trees are predominantly evergreen, and broadleaf trees are predominantly deciduous. In the humid tropic, nearly all trees are evergreen because the climate remains uniform throughout the year. Almost all deciduous forests are located in the Northern Hemisphere. The important dimensions of trees in a wooded area are the diameter of the tree stems at breast height, the average height of the trees, and the average height above ground of the lowest branches.

Figure 43. Mixed vegetation, showing (a) evergreen trees, (b) deciduous trees, (c) brush, and (d) sedges (Northern Manitoba).

84. Low-Latitude Forests

In the low latitudes, tropical rain forests, swamp forests, and moss forests are the principal types.

a. Tropical Rain. In the tropics, rain forests (selva) blanket many square miles of moist low lands in regions where rainfall is heavy and well distributed throughout the year, with no marked dry season. The Amazon Basin and West Central Africa are the two largest areas of tropical rain forest, although it is also found along many rainy coasts and on tropical islands. This type of forest covers more than one-tenth of the earth's total land surface and comprises nearly one-half of the total forest areas of the world. The rain forest consists of broadleaf trees of many species that form a canopy thick enough to shut off most sunlight. The trees are commonly from 30 to 45 meters (100 to 150 feet) in heights, with large diameters, smooth trunks, and few lower branches. *Lianas*, rope-like plants that entwine themselves around trunks and branches, are common. Usually the undergrowth is not dense, although it restricts observation. In the deepest shade, there is usually only a thick mat of ferns or herbs that offers no obstacle to movement. Typical jungle conditions, with thick and impenetrable undergrowth, are characteristic chiefly of sections where light reaches the forest floor, as one precipitous wet slopes, along rivers and coasts, and in abandoned agricultural clearings.

b. Tropical Swamp (fig. 44). This forest occurs in low terrain near or in swampy regions. Mangrove swamp forests (fig. 45) cover large areas along tropical salt-water coasts, presenting an almost impenetrable barrier to movement. This type of forest is found in the soft mud around river mouths, deltas, and inlets, along shallow bays on small islands, and upstream as far as the tidal influence is felt. Mangrove forests include several kinds of trees, all with thick buttressed roots that extend as high as 3 meters (10 feet) above the ground. These spread outward becoming interlaced in a network that makes movement by foot almost impossible and prohibits any type of vehicular movement. Nipa palms, which generally grow in or near mangrove swamps, also present almost impassable barriers (fig. 46).

c. Moss. This forest is found in the higher latitudes just above the rain forest areas, chiefly at altitudes of 915 meters (3,000 feet)

or higher on the tops of tropical mountains wherever high humidity and cloudiness are persistent. The trees are small with long overhanging branches. Moss grows on the branches, tree trunks, and ground, where it is intermingled with ferns and vines to form a blanket that conceals the earth. This moss often covers chasms and ravines, making them appear to be level terrain. The moss forest accordingly is hazardous to movement. It is dark and gloomy and so dense that very little sunlight penetrates the canopy. Visibility is extremely limited.

Figure 44. Swamp forest (air view) (Sanibel National Wildlife Refuge, Florida).

Figure 45. Mangrove swamp (Malay Peninsula).

85. Middle-Latitude Forests

a. Types. The principal forest types in the middle latitudes include Mediterranean scrub forests, broadleaf forests, and needleleaf forests.

b. Mediterranean Scrub. These consist of broadleaf evergreen trees adapted to regions with long, hot periods of summer drought. They are found in the borderlands of the Mediterranean Sea, as well as in California, Chile, southern Australia, and the Capetown region of Africa. These areas are subtropical, with mild, rainy winters and long, dry, hot sum-

Figure 46. Nipa palms (Northern New Guinea).

mers. This type of forest consists of low trees and woody shrubs. Where climate and soil conditions are most favorable, the virgin forest is composed of low, widely spaced trees with massive trunks and gnarled branches. Between the trees the ground is completely or partially covered by a pale, dusty bush and shrub vegetation resembling the soil in color. Cork oaks and olive trees are typical of this type of forest.

c. Broadleaf. Most of the temperate broadleaf forest is composed of deciduous trees with a seasonal leaf fall, such as oak, hickory, maple, ash, elm, walnut, beech, and poplar. Along the humid subtropical margins of the middle latitudes, principally in southern Japan, New Zealand, and southeastern Australia, there are evergreen broadleaf forests that resemble rain forests, with dense undergrowth and heavy vines. Temperate broadleaf forests vary widely in composition, the dominant tree species differing from one region to another. In some areas there are many conifers among them and the forest may be described as *mixed.*

d. Needleleaf. Needleleaf trees are almost exclusively evergreen. The growth and discard of the needles is a continuous process not confined to any particular period or season. Usually the needleleaf forests occupy the colder continental locations on the poleward side of the broadleaf forests. In areas of poor sandy soils, or on steep mountain slopes where soils are thin or rocky and temperatures are lower, needleleaf trees may supplant broadleaf trees even in the middle latitudes. South of the great belts of subarctic needleleaf trees there are large areas of needleleaf trees that provide valuable timber such as the forests of the Pacific Coast, western Canada, and Alaska. The southern pine forests in the Atlantic and Gulf Coastal Plains of the United States also are major sources of timber.

86. High-Latitude Forests

A wide belt of needleleaf forests extends from coast to coast in the subartic regions of Eurasia and North America below the treeless tundra regions. This Eurasian forest is the largest continuous forest area in the world. Needleleaf trees such as fir, spruce, larch, and pine predominate, although in the swamp areas

there are some broad leaf trees such as aspen, willow, birch, or mountain ash. The area has short, cool summers and long, dry, cold winters so that growth is slow, and few trees are more than 0.45 meter (1½ feet) in diameter. There are numerous large swamps and marshes covered with moss, and containing such trees as balsam and spruce. These areas usually rapidly become impassable after precipitation or during a thaw.

87. Shrubs

a. Description. Shrubs are woody plants usually less than 3 meters (10 feet) high with more than 1 stem. They include a variety of trees that have had their growth stunted because of soil or climatic conditions. Scrub growth includes cactus, stunted shrubs, sagebrush, mesquite, and similar plants found most frequently in arid or semiarid areas. Shrubs comprise the undergrowth in the open forests of middle latitudes. In many arid and semiarid areas they are the dominant vegetation. They are prevalent in the subarctic and in large, burned-over or cutover areas in humid regions.

b. Classifications. Shrubs, like trees, are either deciduous or evergreen, needleleaf or broadleaf. In the middle latitudes, most broadleaf shrubs are deciduous, and all needleleaf shrubs are evergreen. In the humid tropics, nearly all shrubs are evergreen. Most arid regions of both low and middle latitudes have some vegetation, both deciduous and evergreen, although it is sparse (fig. 47). It may consist of low bunch grass with widely spaced bushes or fleshy, water-storing plants such as the cacti. Most commonly, the vegetation comprises sagebrush and similar scrub growth. Perennial shrubs of the desert areas grow far apart, with considerable areas of bare soil in between due to the low rainfall. The rate of growth is very slow.

Figure 47. Characteristic desert vegetation (Arizona).

88. Grasses

a. Kinds. Grasses include all kinds of nonwoody plants. A grassland is an extensive area where the natural vegetation consists primarily of grass. In low latitudes, grasslands often are termed savannas; in middle latitudes, prairies (tall grass) and steppes (short grass). Grasslands in wet or poorly drained areas commonly are called meadows. For terrain intelligence

purposes, grass more than (1 meter) 3 feet high is considered tall, and below that height, short.

b. Tropical Grasslands (Savanna). In areas with heavy seasonal rains and a distinct dry season, the grasslands or savanna are composed mostly of tall, very coarse grasses that grow in tufts separated by intervals of bare soil. If there are trees, they usually are species that can withstand seasonal drought and they grow mostly in clumps in the grasslands or along the margins of streams. Savanna grass grows rapidly at the beginning of the rainy season, reaching heights of 1 to 3.5 meters (4 to 12 feet) in a few months. When dry, the blades become brown, stiff, and harsh in texture, burning very readily. The grasses usually diminish in height with decrease in the annual rainfall, and trees become fewer until under semiarid conditions nearly treeless steppes, composed of shorter grasses, are prevalent. Low-latitude savannas are usually located between desert and forest regions.

c. Prairie. The prairie type of grass occurs most frequently in areas where the soil remains moist for a depth of 75 centimeters (30 inches) or more. The prairies are covered with tall, luxuriant, and relatively deep-rooted grasses that grow to heights of from 30 to 90 centimeters (1 to 3 feet). Over most prairie regions, rainfall varies between 50 to 100 centimeters (20 and 40 inches) annually. Usually there is a large variety of flowering plants in spring and summer. The principal prairie regions include parts of central United States and the prairie provinces of Canada; the Argentine Pampa, Uruguay, and southeastern Brazil; the plains of the Danube in Hungary and Rumania; and parts of Manchuria and southern Russia.

d. Steppe. A steppe is an area of short, shallow-rooted grasses typical of semiarid regions where the depth of moist soil is less than 60 centimeters (2 feet). In common usage, the word steppe is used to describe all the drier, short-grass grasslands, both in tropical and middle latitudes. Some of the steppe grasses lie in a soft, fine mat on the ground, while others stand as hard, wiry tufts. Thorny shrubs and low, coarse bushes may dominate the steppe in some sections. Cacti and other succulent plants may be numerous. Steppe vegetation develops typically in regions that receive less than 50 centimeters (20 inches) of rainfall a year, with a hot summer and a cold, dry winter.

89. Cultivated Vegetation

a. Field Crops. Field crops constitute the predominant class of cultivated vegetation. Vine crops and orchards are common but not widespread, and tree plantations are found only in relatively few areas. The size of cultivated areas ranges from paddy fields covering a quarter of an acre to vast wheat fields. In a densely populated area, where all arable land is cultivated, each parcel will be used for the crop that brings the highest yield, making it possible to predict the nature of the soils from information about the predominant crops. Rice, for example, requires fine-textured soils. Other crops generally must have firm, well-drained land.

b. Orchards. An area of orchards or plantations usually consists of rows of evenly spaced trees, showing evidence of planned planting that can be distinguished on an aerial photograph. Usually such an area is free from underbrush and vines.

c. Rice Fields. Rice fields usually are flooded areas surrounded by dikes or walls approximately ½ or 1 meter (1½ to 3½ feet) in height and ½ to 1½ meters (1½ to 4½ feet) wide. When flooded for planting, the depth to the bottom mud ranges from 15 to 90 centimeters (6 inches to 3 feet).

90. Military Aspects

a. Key Terrain. Woods provide concealment and cover for assembly areas and during the approach march. Forests and heavy vegetation, however, increase the difficulty of maneuver in advancing to attack and in launching the assault. The attacker may have little or no information about the roads, trails, and topography in the area not under his control, due to the difficulty of securing detailed terrain intelligence without actual reconnaissance. Wooded and heavily vegetated areas provide cover and concealment for organized positions, shelter for reserve formations, and an obstacle to the attacking forces. Usually the defender

is able to make a detailed reconnaissance of the area, so that he is familiar with the roads, trails, and other features of the terrain. Infantry weapons form the basis of the defense, due to the difficulty of securing observed artillery fire in heavily wooded areas.

b. Observation and Fields of Fire.

(1) *Observation.* The height and density of the trees and other vegetation largely determine the amount of ground observation that can be obtained. To secure an adequate field of view from an observation post, it may be necessary to clear away vegetation at the risk of losing concealment. The effects of cultivated crops upon observation vary with seasonal conditions. In two or three weeks a cornfield may be covered with high stalks that limit observation. Later in the season, this corn may be harvested in a day, allowing observation again.

(2) *Fields of fire.* Lanes may be cut through vegetation to provide fields of fire, but it is seldom practical to cut lanes that extend far enough to provide long-range observed fires. Extensive clearing indicates the location of weapon positions to the enemy. The extent of clearing that is practicable will depend upon the amount of vegetation, its density, and the length of time that the positions will be occupied. Indirect fire is less affected by vegetation than direct fire. Mortars require little more than overhead clearance. Artillery weapons require more clearance than mortars, but high angle fire may be employed to avoid extensive cutting and clearing. Air defense artillery can be employed effectively in forests and areas of heavy vegetation when clearance requirements are met. Forests and heavy vegetation may be set on fire as a tactical weapon, particularly during dry season. Wooded areas and those covered with heavy vegetation tend to increase the persistence of gas and smoke, particularly during wet seasons or periods of high humidity. The influence of forests and heavy vegetation upon nuclear weapons effects varies with the amount of overhead cover, density of growth, kind of trees, nature of the tree crowns, undergrowth, and the litter on the forest floor. Trees in leaf offer a high degree of protection from thermal radiation if the cover is sufficiently continuous, but protection from initial nuclear radiation is insignificant.

c. Cover and Concealment. Thick forests of deciduous trees in leaf give excellent concealment from air observation when troops observe proper precautions in camouflage and movement. Evergreen forests will provide concealment throughout the year, changing color very slightly from season to season. Deciduous trees lose their leaves, reducing concealment, and change color, which increase the difficulty of natural camouflage. Usually undergrowth and small trees growing closely together give better concealment from ground observation than a stand of larger trees. Unless the undergrowth is high, however, it will provide little concealment from aerial observation. The amount of concealment and cover provided by cultivated crops depends largely upon seasonal conditions. Disruption of the agricultural pattern is readily apparent to aerial observers and in aerial photographs.

d. Obstacles. Fire lanes and certain types of vegetation often canalize movement through forest areas. This is true, for example when lines of trees border streams. Normally, no serious obstacle to movement is offered by shrubs and grasses, but visibility can be reduced in high grasses, with the added danger of reptiles to foot soldiers. Small grain crops hold soil nearly as well as grasses, so that movement is better in such areas than in those planted with row crops. Some parts of vineyards present a tangled maze of poles and wires that constitute a definite obstacle to vehicles and dismounted troops. The terraces and retaining walls on hillsides are also obstacles. Wheeled vehicles and some tracked vehicles are unable to cross flooded paddy fields, although they can negotiate them when the fields have been drained and the soil is thoroughly dry. In some cases even dried paddy fields remain

a serious obstacle to movement because some vehicles are unable to negotiate the dikes surrounding the fields.

e. Avenues of Approach. In most wooded areas, individual trees large enough to stop a tank are seldom so close together that they cannot be bypassed. Closely-spaced trees usually are of relatively small diameters and can be pushed over by a tank. The smaller trees and undergrowth, however, may be so dense that when they are pushed over the resulting mass of pileup vegetation will stop the tank. In most cases, wooded areas slow down the movement of tanks, and a guide may be required to lead each vehicle. Cutover portions of wooded areas usually contain stumps hidden in tall grass or weeds that are serious obstacles to armor. Trees that can stop a wheeled vehicle usually are too closely spaced to be bypassed. The pileup effect from pushing over vegetation is greater for wheeled vehicles than for tanks. Trailed loads are difficult to tow through wooded areas. Woods slow down the movement of dismounted troops. Some types of vegetation, such as mangroves or dense jungle, are frequently impenetrable until routes are cleared.

*f. Construction.*The usefulness of trees for timber is determined by their height and diameter, and by the nature of the wood as hard, soft, or fibrous. Deciduous trees generally are hardwoods. Needleleaf trees are softwoods that usually are easily worked, although some species are fibrous and difficult to saw. When a forest area must be cleared of trees prior to a construction project, a study of the ground will indicate the density and depth of the root systems. Where a forest is closely underlain by hardpan or rock, tree roots branch and remain near the surface, making them easy to uproot. In soil that is firm, with deep underlying rock, trees tend to form large taproots extending to a considerable depth, making them difficult to remove. Trees in inundated, marshy, and muskeg areas have thick widespreading and shallow root systems near the surface of the ground. In northern regions where permafrost occurs, its effect on the root systems of trees is similar to that of hardpan or rock. Where the permafrost is near the surface, the roots branch and lie close to the surface. Deeper taproots are developed where the permafrost is far below the surface.

91. Information Requirements—Vegetation

As far as practicable, information about the vegetation in an area is presented in the form of a map overlay that clearly indicates and identifies the major vegetation types by the use of color and symbols. The accompanying text briefly summarizes the additional information of military significance that cannot be shown adequately on the map. Pertinent information may include the following:

a. Forests.

(1) Name or other identification.

(2) Plant associations.

(3) Principal species (names, proportion in percent, density or average spacing, height range).

(4) Undergrowth species.

(5) Canopy: structure (continuous, open, broken) and seasonality (color, defoliation).

(6) Duff (partly decayed vegetable matter on the forest floor): abundance and nature of fallen trees, logs, and so on.

(7) Exploitation practices (normal cutting, overcutting, undercutting).

(8) Operational aspects (suitability for cover, concealment, blowdown susceptibility, camouflage, and fuel).

(9) Principal tree species.

(*a*) Name (English and botanical).

(*b*) Height (average).

(*c*) Growth form (triangular, linear, and ovate).

(*d*) Diameter (average).

(*e*) Leaves (broadleaf or needleleaf).

(*f*) Period of defoliation.

(*g*) Roots (structure, size, toughness).

(*h*) Suitability for construction.

(*i*) Special features (toxicity, thorniness, edibility).

(*j*) Indicator significance relation to

regional and local climates, kind and state of ground, and ground water, salinity, permafrost, depth and duration of snow cover, human activity).

b. Shrubs.

(1) Location and areal extent.

(2) Name or other identification.

(3) Principal species (names, proportion in percent, density or average spacing, height range).

(4) Foliage—density and seasonality (color, defoliation).

(5) Operational aspects (susceptibility to mass conflagration).

(6) Principal shrub species (for each). (Same information as for tree species.)

c. Grasses.

(1) Location and area extent.

(2) Identification.

(3) Principal species (names, proportion in percent, density, height range).

(4) Seasonality (dates of growth, color).

(5) Operational aspects (susceptibility to mass conflagration).

(6) Principal species (for each).

(*a*) Name (English and botanical).

(*b*) Date of maturity, height.

(*c*) Life span.

(*d*) Growth habit (sod or bunch).

(*e*) Suitability as forage.

(*f*) Special factors (toxicity, irritancy).

(*g*) Indicator significance.

d. Cultivated Crops (general).

(1) Location and areal extent.

(2) Name or other identification.

(3) Principal crops (names, proportion in percent, density or spacing height range; if applicable, months planted, cultivated, and harvested; crop rotation practices).

(4) Canopy, foliage, or stand (as applicable: structure, color, defoliation, density, rates of growth).

(5) Types of farming (irrigated, dry, and so on).

(6) Special factors associated with crops (irrigation ditches, flooding, terraces, hedgerows, dikes, and stone or other types of fences).

(7) Operational aspects (susceptibility to mass conflagration).

(8) Principal crops.

(*a*) Tree and shrub crops (same information as for tree species; in addition, months that the crops are harvested).

(*b*) Grass and grain crops (same information as for tree species; in addition, months of planting and harvesting).

CHAPTER 6

MANMADE TERRAIN FEATURES

Section I. SIGNIFICANCE

92. Definition

Manmade features include all the changes in the natural environment made by man in the course of living on the earth and using its resources. Major manmade features are cities, defensive works, transportation and communication facilities, and similar features that have significant effects upon the military operations. Others are such features as cemeteries, hedgerows, and buildings, which affect only local operations.

93. Military Aspects

In preparing terrain studies, manmade features must be evaluated to determine their effect upon the military aspects of proposed operations. Recommendations may be made to destroy certain features or to retain them for future use after the operation has been completed. Usually each major manmade feature is the subject of a detailed study by military intelligence personnel.

Section II. LINES OF COMMUNICATION

94. Importance

The lines of communication of an area consist of all the roads, railways, and waterways over which troops or supplies can be moved. The importance of particular features will depend upon the unit and the type of operations. The ability of an army to carry out its mission depends greatly upon its lines of communication. One of the primary considerations in planning large-scale operations is the extent and general nature of the transportation network. Planners must consider the advantages and disadvantages of the entire pattern of transportation facilities. An area with a dense transportation network, for example, is favorable for major offensives. One that is criss-crossed with canals and railroads, but possesses few roads, will limit the use of wheeled vehicles and the maneuver of armor and motorized infantry. Railroads extending along the axis of advance will assume greater importance than those perpendicular to the axis, and the direction of major highways and waterways assumes equal significance.

95. Roads and Routes

a. Description. The term roads includes all types of roads and tracks, but pack trails and foot paths are not included. Bridges, ferries, snowsheds, and similar structures and facilities that provide continuity of movement and protection for the way are also considered as integral parts of the road system. An adequate road system is a fundamental requirement in the conduct of any major military operation. Terrain studies must provide information about the roads which exist in the area under consideration and should indicate any major repair or rehabilitation required on existing roads, or where now roads will be needed to support a proposed operation. Roads in the combat zone usually need meet only minimum standards, but those in rear areas, especially in the vicinity of water terminals, airfields, supply installations, and those used as MSR's must be well-surfaced and capable of carrying heavy vehicle traffic without excessive maintenance. Operations on a wide front and the employment of nuclear weapons will require

a large number of secondary roads in both forward and rear areas. The information presented in a terrain study should indicate the minimum maintenance and construction requirements that may be anticipated during a planned operation. Continual maintenance of road net is essential. In addition to the severe punishment given to roads by large volumes of heavy traffic, important bridges, intersections, and narrow defiles are primary targets for enemy bombardment. The maintenance of unnecessary roads must be avoided, and the construction of new roads held to a minimum.

b. Route Types. Routes usually are classified as follows:

(1) *All-weather route (Type X).* Any route which with reasonable maintenance is passable throughout the year to a volume of traffic never appreciably less than its maximum capacity. The roads which make up this type of route have a waterproof surface, adequate drainage, and are only slightly affected by precipitation or temperature fluctuations. At no time is it closed to traffic by weather effects other than snow blockage. In this route class are roads paved with concrete, bituminous surfacing, brick, or paving stone.

(2) *All-weather route (Type Y) (Limited traffic due to weather).* Any route which with reasonable maintenance can be kept open in all weather, but sometimes only to traffic considerably less than maximum capacity. The roads which form this type of route do not usually have waterproof surfaces and are considerably affected by precipitation or temperature fluctuations. Traffic may be halted completely for short periods. Heavy use during adverse weather conditions may cause complete collapse of the surface. Crushed rock or waterbound macadam, gravel, stabilized soil, or sand-clay, are typical roads in this route class.

(3) *Fair-weather route (Type Z).* A route which quickly becomes impassable in adverse weather and cannot be kept open by maintenance short of major construction. This type of route is so seriously affected by weather that traffic may be brought to a halt for long periods. In this route class are roads of natural or stabilized soil, sand-clay, shell, cinders, laterite, and other lightly metalled or light aggregate surfaces.

c. Location and Use. Military routes are classified also as follows:

(1) *Axial route.* Axial route is part of military road net work, and it leads toward the front and is generally perpendicular thereto. When designated as the principal traffic artery of a division or higher unit, such a route is termed a main supply route (MSR). When designated the principal traffic artery of a brigade or battalion, such a road is termed a supply route (SR).

(2) *Lateral route.* A route which generally parallels the front and leads into and across axial routes.

(3) *Reserved route.* A controlled route allocated exclusively to a command or unit, or intended to meet a particular requirement.

(4) *Supervised route.* A route over which control is exercised by means of traffic control posts, traffic patrols, or both.

(5) *Dispatch route.* A route over which full control, both priority and regulation of traffic, is exercised.

d. Adverse Terrain. Swamps, bogs, and lowlands such as delta areas may create special problems of drainage and ditching, necessitate added support to the roadbed and require the construction of many bridges. Rugged topography may result in steep grades and sharp curves, tunneling, bridging, cuts, and sidehill locations in laying out new roads. Sidehill locations, in turn, may require retaining walls, cribbing, and snowsheds to give protection against earth, rock, or snow slides. In the desert, sand fences and special crews and equip-

ment to keep the roads clear of drifting sands may be required. Arctic terrain requires special techniques to build and maintain roads on permafrost and periodically frozen ground.

e. Weather and Climate. Sustained periods of freezing, heavy snowfalls, and similar extreme weather conditions may seriously affect the use, maintenance, and construction of roads. Protection must be provided against snow drifts, and provisions made to remove the snow and to repair damage due to frost heave and frost boils. Excessive rainfall may result in washouts and flooding in low areas and cause earth and rock slides in rugged terrain. Continuous wet weather may make unsurfaced roads impassable. In dry periods, dust control becomes an important factor on unsurfaced roads.

f. Design and Construction. Terrain studies should include an engineering evaluation of the structural soundness of all roads in an area under consideration. If the initial design did not provide for the increased loads and speeds that would accompany military use or if the road was improperly constructed originally, it may prove a serious obstacle to movement. Repairs and excessive maintenance may be required because of an unstable subgrade; inadequate drainage of the subgrade, surface, or slopes; sharp curves, and loose or unsealed wearing surfaces that result in saturated roadbeds.

g. Poor Maintenance. Poor maintenance of a road is shown by clogged culverts and ditches, potholed, bumpy, and rutted surfaces, soft and uneven shoulders, and badly worn and cracked pavements. Studies should indicate where these conditions exist and the maintenance that would be required to bring the roads up to minimum military standards.

h. Trafficability. The various types of soils affect trafficability differently. For example sandstone affords excellent trafficability when it is dry but is reduced to good trafficability when wet; trafficability on a clay surface is rated as fair when dry and impassable when wet.

96. Information Requirements — Roads

a. Information about roads is recorded on map overlays that show the alinement of the significant roads, with the location of associated bridges, tunnels, ferries, fords, and critical points such as rockslide areas. Ordinarily the local system of route numbers is used, but if no system exists that is satisfactory for terrain intelligence purposes, an arbitrary system is used to identify the main and secondary roads.

b. Information about individual roads usually includes the following:

(1) Name and route number.

(2) Terminal points; intermediate localities on the road; distances between major points.

(3) Terrain (elevations, irregularities, slopes, drainage, soils).

(4) Length and width.

(5) General condition (necessary repairs and improvements, with nature and location).

(6) Surface material (by sections, if there are changes in type of surface along the route).

(7) Ratings of alinement, drainage, foundation, and surface.

(8) Roadbed (width of traveled way; type and width of shoulders).

(9) Maximum grade.

(10) Sharpest curvature.

(11) Significant cuts and fills.

(12) Clearance (minimum vertical and horizontal clearances, with nature of restrictions).

(13) Bridges (load capacity, general condition).

(14) Tunnels (length, widths, clearances, condition).

(15) Fords and ferries (type, general characteristics, condition).

(16) Critical points; location and characteristics of possible bypass routes or detours around bottlenecks.

(17) Location and characteristics of routes that provide maximum protection from ground or air attacks.

(18) Snow (critical areas, snow fencing, snow removal equipment).

97. Bridges

a. Importance. Road and railway bridges are vulnerable points on a line of communication. Timely preservation, destruction, or repair of a bridge may be the key to an effective defense or to successful penetration of an enemy area. A bridge seized intact has great value in offensive operations, since even a small bridge facilitates the movement of combat troops across a river or stream. Information about bridge types and their classification is contained in **TM 5–312** and **FM 5–36.**

b. Sites. Because of the time and labor involved, new bridges are erected only when an existing bridge, ford, or detour cannot be used. Terrain suitable for a bridge site should meet the following requirements:

(1) Satisfactory river conditions, with no fast currents or great depths.

(2) Site readily accessible from the road it serves.

(3) Firm, well-drained approaches, preferably above flood level.

(4) For floating bridges, a riverbed free from snags, rocks, and shoals to a minimum depth of three feet and firm enough to hold anchors and to support trestles. Banks should be from two to six feet above water level to minimize excessive abutment preparation.

(5) Firm, stable banks of suitable height. Large differences in bank height require excessive grading. Low banks may be subject to a rising river level that will flood the bridge site.

(6) Adequate, well-drained working areas close to the site including a bivouac for the working party, space for construction materials, and turnarounds and parking places for vehicles and heavy mobile equipment.

(7) Areas close to the site, near or alongside the approach roads, where vehicles can park off the road and under cover while awaiting their turn to cross.

98. Information Requirements — Bridges

a. Detailed information about bridges cannot be obtained from topographic maps, but indications on air photographs usually will permit an approximate determination of the width, clearance, and height above water of a bridge. Details such as the condition, capacity, and structure of a bridge should be obtained by engineer reconnaissance. Reconnaissance procedures are described in **TM 5–312** and **FM 5–36.** Basic information requirements for a bridge should include a summary of its structural characteristics, its critical dimensions (length, usable width, overhead clearance), an estimate of capacity, and general condition.

b. Detailed information includes the following:

(1) Type, number of lanes and width of each, number of spans and length of each length of panels, arrangement of spans.

(2) Height above riverbed, overhead clearance for vehicles, class.

(3) Stream data: width, depth, velocity of current, direction of flow, type of bottom, estimated bearing capacity of bottom, height, slope, and nature of banks.

(4) Description, dimensions, and condition of access roads and approaches.

(5) Type, dimension, and condition of abutments, stringers, flooring, girders, and other structural elements.

(6) If damaged or wrecked—

(*a*) Structural details of bridge in its original form.

(*b*) Nature and extent of damage; position of debris; details regarding any salvageable materials.

(*c*) What loads, if any, can still cross the bridge.

(*d*) If not suitable for use, information about alternate sites.

99. Railways

a. Property. The term railway includes all

fixed property belonging to a line, such as land, permanent way, bridges, tunnels, and other structures. Railways assume increased military importance in areas where the soils are generally untrafficable, roads are poor, and rail transportation facilities are extensive. Frequently, railways can be used as substitute roads for vehicles. Most railway bridges will carry tanks without reinforcement. The basic elements of a railroad include motive power, rolling stock; trackage; yards, terminals, regulating stations, and railheads; transshipment points; water and fuel stations; maintenance and repair facilities; and signal communication facilities.

b. Yard. A yard is an area containing a system of interconnected tracks and is used for making up trains, storing cars, and general maintenance activities.

c. Railhead. A railhead is the point at which supplies destined for a particular unit, installation, or area are transferred from rail to another type of transportation, usually trucks.

d. Regulation. A regulating station is an installation on a military railway line at which the movement of supplies and personnel is controlled. Its facilities include a yard, open and covered storage, and usually, temporary housing and messing facilities for transient personnel.

e. Construction. The development and extent of a railway system largely reflect the topography of the region that it traverses. In desert regions, for example, a single railroad may extend in a straight line across vast barren wastes. In hill regions and mountain areas, the railways run through valleys, with short lines leading off into other terrain. On plains, railways will have few curves but may be subject to the effects of poor drainage conditions. Generally, railways tend to follow rivers because of the more uniform grades, the availability of straight routes, and the concentration of resources, industries, and population centers along the waterway. The terrain characteristics of an area can be determined to a considerable degree by a study of the railway routes, since the rail lines almost invariably follow the topography that offers the fewest obstacles.

f. Military Use. Railways are desirable for extended military operations. Their capabilities are of primary concern and are the subject of continuing studies by personnel at the highest levels. Detailed intelligence about the railways in an area of operations is produced by specialists of transportation and engineer units. Railways are highly vulnerable to enemy attack, particularly to sabotage and guerrilla operations. Keeping a railroad line in operation requires trained security forces and extensive protective measures.

100. Evaluation of Railways

In evaluating a railway for terrain intelligence purposes, consideration should be given to the effects of adverse terrain, weather and climate, and the overall design and construction of the system. The following factors should be considered:

a. Adverse Terrain. Railways passing over swamps, bogs, and delta terrain may encounter special problems of drainage, ditching, and roadbed maintenance. In mountainous areas, steep grades, sharp curves, and tunnels are common. Because of sidehill locations and deep cuts, there should be protection against earth, rock, and snow slides. In desert, drifting sand is a problem and provisions should be made to remove it.

b. Adverse Weather and Climate. Severe winter conditions seriously retard operation and maintenance of railways, requiring protection against drifting snow, provisions for snow removal, and repairs because of damage caused by frost heave. Excessive rainfall may result in washouts and flooding in low areas and cause earth and rock slides in rugged terrain.

c. Design. A railway may prove inadequate because the initial design did not provide for the increased loads and speeds or heavier volume of traffic needed. As a result, a railway might require either considerable reconstruction and repair or extensive maintenance. Among the more common defects are an unstable subgrade, lack of adequate drainage, light rail, poor ballast, and untreated ties. Improper maintenance is evidenced by such con-

ditions as an uneven roadbed, improperly tamped ties, loose fastenings, badly worn rail, or uncleared drains.

101. Information Requirements — Railways

Railway information should be recorded on a map or overlay that shows the true alinement of all rail lines; their trackage, gage, and status; and the location of selected bridges, tunnels, and ferries. A convenient system of line numbers is used based on a standard reference or arbitrarily selected. Fundamental information about railways should include the following:

a. Total mileage.

b. Terminals and details of main lines.

c. Mileage by gage and locations of changes.

d. Number of tracks.

e. Maximum grade and minimum radius of curvature.

f. Location and length of passing tracks.

g. Type and weight of rail.

h. Permissible loads; capacity of bridges.

i. Yards and terminals (location, type, capacity).

j. Details of servicing facilities and other installations.

k. Operating factors (cars per train; speed; number of daily trains each way).

l. Bridges and tunnels (bridge data to include length, number of tracks, spans by type and length, height of structure; tunnel data to include length, number of tracks, and lining).

m. Rail ferries (location, type, capacity).

n. Electrification (location, type).

o. Transshipment points.

p. Individual rail line details—

(1) Name.

(2) Terminals, intermediate stations, length of each stretch.

(3) Obstructions (demolitions, washouts, blocked tunnels).

(4) Gage.

(5) Number of tracks.

(6) Weight of rails.

(7) Maximum grade and minimum radius of curvature with location of each.

(8) Ties, ballast.

(9) Sidings and passing tracks (location, lengths, switches).

(10) Tunnels (locations, clearances).

(11) Overhead structures and vertical clearances.

(12) Drainage facilities, including culverts.

(13) Bridge data.

(14) Operating and servicing facilities (location, availability of fuel and water and ice; signal, traffic control, and dispatching facilities).

(15) Availability of trained and dependable personnel.

(16) Transshipment points.

q. Equipment.

(1) Present condition, and interchangeability with equipment of other countries.

(2) Motive power (type, size, weight, tractive effort, wheel arrangement, type and height of couplings).

(3) Rolling stock (type, number, car dimensions, capacity, weight).

(4) Rail cars self-propelled and trailer-type, total by type, size, capacity.

(5) Work cranes (total by type, size, capacity).

(6) Snow plows (total by type, size).

(7) Armored equipment (total by type, size).

(8) Repair shops (location, types of equipment repaired, capacity by type, number of personnel employed).

102. Inland Waterways

a. Definition. The term inland waterway is

applied to those rivers, canals, lakes, and inland seas of a country which are used as avenues of transport. It includes all the fixed structures which affect the movement of vessels carrying passengers or freight. Types of inland waterways include inland lakes and land-locked seas, rivers, and ship and barge canals, and the intracoastal waterways, usually running parallel to the coastline of a land mass and sheltered enough to permit the navigation of small vessels.

b. Classification. Inland waterways can be classified according to their depths as follows:

(1) *Very shallow.* Depths less than 1.4 meters (4½ feet).

(2) *Medium.* Depths between 1.4 and 2 meters (4½ and 6½ feet).

(3) *Deep.* Depths greater than 2 meters (6½ feet).

c. Advantages. Inland waterways provide an economical form of transportation for bulk supplies, freeing faster modes for shipments of a higher priority. Frequently, large or very heavy items that cannot be handled by truck and rail can be shipped by waterway. One of the major uses of waterways in an active theater is the transportation of supplies for the rehabilitation of the economy in liberated areas, thus reducing the demands upon military transportation facilities.

d. Limitations. Unless icebreaking operations can be conducted, traffic is halted completely during a freezing period. The thaw following a freezeup may cause floods, and periods of drought may result in insufficient water for the movement of vessels. The locks, bridges, cuts, dams, and other facilities are vulnerable to enemy action. Retreating enemy troops usually drop rail or road bridges into the waterway; damage locks and levees; obstruct channels with ships and barges; drain canals; and destroy, dismantle, or move essential equipment. Waterway transport is slow. It is also inflexible, since new waterways cannot be constructed during military operations. The depths of rivers and streams used as waterways fluctuate with maximum and minimum rainfall. Streams with fairly direct courses commonly are interrupted by falls and rapids. Streams of low and uniform gradients usually meander. Their channels shift constantly, depositing sandbars, which are a menace to navigation.

103. Information Requirements — Waterways

Inland waterway information should be recorded on a map or overlay that shows the true alinement of the navigable waterways, the location of all locks, dams, aqueduct bridges, tunnels, and major landing facilities, and the location of specific structures which limit the vertical and horizontal clearances on each navigable reach. The local names are used to identify waterways and structures whenever feasible. Detailed information requirements should include the following:

a. Developed Waterways.

(1) Geographical location (name, origin, terminus, length).

(2) Restricting widths and depths of channel.

(3) Frequency, duration, and effects of seasonal changes (floods, low water, droughts, excessive currents, normal freezeup and opening dates).

(4) Location, description, and restrictive effects of structures (locks, safety gates, dams, bridges, ferry crossings, aqueducts, tunnels, cable crossings).

(5) Speed and fluctuation of current.

(6) Name and location of waterway ports, including length of alongside wharfage and depths, and data on mechanical handling, storage, clearance and ship repair facilities.

(7) Maintenance requirements.

(8) Craft (number, type, cargo capacities).

(9) Communication facilities.

(10) Availability of labor force.

b. Navigable Rivers. In addition to the items listed in *a* above, the following additional information may be required:

(1) Physical characteristics of the river

(bottom, banks, feedwater streams, and important tributaries).

(2) Navigational hazards, such as falls, rapids, and sandbars.

(3) Navigational aids, location, and type (buoys, lights, range markers, radar, foghorns).

(4) Changes in channel.

(5) Dredging requirements.

Section III. PETROLEUM AND NATURAL GAS

104. Location

a. Source. Oil is found only in the stratified sedimentary rocks and sands of ancient sedimentary basin areas. Because of geologic upheavals in past ages, today's oilfields may be found along the foot of mountain chains or in lowland or offshore areas. Petroleum, gas, and water are commonly found together.

b. Gas. Natural gas is found alone, as well as with petroleum. Gas from oil wells is commonly entrained with natural gasoline and is known as wet gas. When economically feasible, wet gas is piped to an absorption plant, where the gasoline is extracted. Gas from gas wells ordinarily is relatively free of natural gasoline and is known as dry gas. If sufficiently free of other unwanted gases and impurities, dry gas may be fed directly into pipelines for distribution.

105. Installations

a. Derricks are commonly the most distinguishing features of an oil or gas field. A derrick is required to position and handle the long sections of drill pipe and other equipment used in the well when drilling for oil. Depending on the type, the cost of moving or future needs, a derrick may or may not be left in place indefinitely following the completion of the well. Where a continuing need exists, the drilling derricks may be replaced with smaller derricks or gin poles. A producing oil well is characterized by a pump or by a "Christmas tree," so called because of its tree-like appearance. A pump is used where the subterranean gas pressure is too low to force oil to the surface. A Christmas tree is used where the underground gas pressure is sufficient to force oil to the surface. It consists of a system of pipes, valves, and gages capping a well for controlling the flow of crude oil and gas.

b. Refineries are located near either producing oil fields or distribution centers in major consuming areas. Adequate all-weather transportation and an abundance of cooling water are essential. Tall, cylindrical distillation or "cracking" towers are the most prominent features at refineries. Other equipment includes large furnaces, cooling towers, electric power plants or substations, and intricate piping systems. Tankage for storing crude oil charge stocks and semirefined and refined products is also required. Refinery capacities are usually rated in barrels per day (42 U.S. gallons per barrel) or metric tons per year of crude oil run to stills (crude oil started through the refining processes). A reliable rule of thumb for converting barrels per day to metric tons per year is to multiply the number of barrels per day by 50. Metric tons per year are divided by 50 to yield barrel-per-day figures. Crude oil for refinery fuel or lost otherwise amounts to about 7 to 10 percent of refinery capacity.

106. Distribution

a. Systems. A bulk distribution system for petroleum products may include ship-to-shore and dockside loading and unloading facilities, bulk storage tank farms, pipelines, pumping stations, bulk delivery points or pipeheads, warehouses, open storage areas, canning and drumming facilities and testing laboratories. Ocean-going tankers, tank barges, railroad tank cars, and tank trucks are also included in integrated distribution systems. For terrain intelligence purposes, pipelines and storage facilities are the most significant features of a distribution system.

b. Pipelines. Pipelines commonly consist of piping, pumping equipment, and regulating tankage. Other supporting equipment may include tele-communications facilities, cleaning

devices and trays for removal of unwanted condensates or contaminants, control and heating devices. The capacity of a pipeline is expressed as a quantity of liquid capable of being transported per unit of time, ordinarily in the number of barrels, metric tons, or cubic meters per day. The quantity of fuel actually transported, usually will not exceed about 85 percent of the pipeline capacity.

c. Military Pipelines. Military pipelines are used chiefly to transport jet fuel and gasoline. Occasionally they are used also to transport diesel fuel and kerosene. Commonly, 15-cm (6-inch) pipe is used; 20-cm (8-inch) pipe is employed for ship unloading or trunk lines. The pipeline follows the most direct level route, within six to nine meters (20–30 feet) of all-weather roads, so as to facilitate construction, partrol, repair, and security of the line. Cross-country cutoffs are used where roads wind excessively. A military pipeline is diverted around difficult terrain, such as marshes, swamps, or land that is subject to periodic flooding. It also avoids populated areas and military installations that have a high element of hazard, such as ammunition dumps. Base terminals are located in rear areas, at or near theater ports of embarkation or other tanker unloading points, but pipehead terminals are located at the forward end of a military pipeline, moving forward with the army supply point to support the advancing forces.

d. Civilian Pipelines. Civilian pipelines are important for potential military support. They are generally permanently installed cross-country along the most economical route. These pipelines may range from about 10 cm (4 inches) to more than 100 cm (40 inches) in diameter. Pipe of extremely large diameter is ordinarily used only for natural gas or crude oil. Pipelines for crude oil are much more common than those for refined products, although use of the latter is rapidly growing. Crude oil pipelines can be converted for handling refined products. This is a costly and time-consuming undertaking, particularly if aviation-grade fuels are to be transported.

e. Tanks. Bulk petroleum and refined products are stored in tanks which differ greatly in size, shape, and construction, according to the function of the tanks and the nature of the product stored. The tanks may be completely above ground, partly or entirely buried. Tanks above ground are surrounded by dikes or low walls to form catch basins and to prevent the occurrence or spread of fires if the tanks are ruptured or overflow. Tanks are buried or partly buried for reason of safety, to reduce evaporation losses, for concealment, or to reduce their vulnerability to military attack. A group of storage tanks is called a tank farm. Tank farms vary greatly in size; some comprise major storage complexes, with storage capacities of millions of barrels. Ordinarily, the tanks are interconnected by an assembly of pipes and valves called a manifold, which permits the movement of products. Because of their vulnerability to air attack, and to nuclear attack, military tanks farms are limited to a total capacity of no more than 250,000 barrels. Military storage tanks are made of steel or aluminum and have capacities up to 10,000 barrels. Portable fabric tanks also are used in military operations at forward supply points and at beachheads.

107. Military Importance

a. Targets. The petroleum and natural gas resources of a country or region are valuable assets to its economy, and the degree of self-sufficiency in military fuels is fundamental to its conventional military capabilities. Accordingly, refineries, terminal facilities, distribution systems, and storage installations are primary targets for air attack and are major objectives. Major oil producing areas and refineries, key pipelines, storage facilities, and marine terminals may be the principal objectives of a campaign to seize them for our use or deny them to the enemy. The most militarily significant natural gas facilities are pipelines, which could be readily converted for handling petroleum products for military support.

b. Planning. Because military planners are interested in the availability of fuel for military use, avoiding possible disturbance to local economics, the typical normal operating conditions with respect to petroleum facilities are important. Included are seasonal variations in the supply and demand for petroleum products, and the principal consumers and their needs. Manufacturing and civil transport

fuel requirements, as well as agricultural consumption by tractors and irrigating systems are militarily significant in modern planning.

108. Information Requirements — Petroleum and Natural Gas

The location and extent of petroleum and gas facilities should be recorded on a topographic map of suitable scale. A numbering system is established to identify the petroleum and the gas pipelines, producing fields, plants, and storage facilities. A separate series of numbers is used for each pipeline. Such pipeline facilities as pumping stations and tank farms are numbered serially, beginning from a designated initial point on the line. Local names may be used for individual installations. Basic information should include the following:

a. General.

(1) Location and type of raw material (oil, oil shale, natural gas); character of crude oil; well logs; and a geologic column which designates the producing formations and the depth to producing horizons.

(2) Reserves of raw material in million barrels, metric tons, or million cubic feet (cubic meters).

(3) Administrative, maintenance, and repair facilities.

(4) Security and safety provisions.

(5) Physical condition of installations and equipment; required major repairs or improvements.

(6) Availability of trained and reliable personnel.

(7) Principal consumers.

b. Refineries.

(1) Location and owner/operator.

(2) Capacity.

(3) Details of construction; type of equipment.

(4) Nature and quality of products produced.

c. Pipelines.

(1) Name, if any; location of lines; material transported.

(2) Terminals.

(3) Number and diameter of pipes; delivery capacity of system at present and under normal conditions; content of pipeline when full.

(4) Facilities at base terminal (if a water terminal, method of loading from tankers).

(5) Storage facilities at terminals and along pipelines; capacity of each installation.

(6) Pumping stations (location, capacity, equipment).

d. Storage.

(1) Location: geographic coordinates; topography; adjacent landmarks.

(2) Surface tanks: types and number; dimensions; protection (revetments, blast walls).

(3) Buried tanks; number; dimensions.

(4) Pump houses: location; number; dimensions; capacity.

(5) Connecting pipelines and distributing systems.

(6) Stocks (location and type).

Section IV. MINES, QUARRIES, AND PITS

109. Mines

a. Mineral Resources. The important mineral resources of a country include metallic ores such as iron, copper, zinc, lead, tin, silver, gold, and uranium; mineral deposits, principally sulfur, phosphate rock, gypsum, graphite, asbestos, and bauxite; and solid fuels, chiefly coal, lignite, and peat. Terrain studies list each significant mineral, covering in detail the estimated quantities available and the methods and facilities employed to mine, process, and distribute each type of mineral. Mineral deposits are exploited either from the surface of the ground or from underground shafts and tunnels, the method depending upon the depth

of the deposit below the surface. A typical underground mine consists of a vertical shaft, horizontal passages opening out of the shaft, and passages driven from above (winzes) connecting the levels. Openings branching off from the levels, where the ore is actually extracted, are called stopes. Supports in mine working usually are made of timber treated with preservatives or of reinforced concrete, steel, brick, or stone. Pillars of ore may be left as supports, finally being mined when the workings are vacated. Where ore beds lie close to the surface, the mineral may be removed from open pits after stripping off the overlying earth and rock. This is strip mining, the coal or other mineral being removed by power shovels.

b. Placer. Placer mining involves the removal of the unconsolidated rock material that lies above bedrock by hand, hydraulic nozzles or dredges, and subsequent separation of the ore from waste by panning and sluicing. It is widely employed to mine gold.

c. Open-pit. In open-pit mining, an excavation is made. In the case of deep pits, the sides usually are cut into steps or benches. Access to the below-ground-level site may be obtained by arranging these benches in spiral form, by cutting inclined approaches, or by sinking a shaft connected to the mine by an adit or tunnel (fig. 48).

Figure 48. Open-pit copper mine.

d. Glory-Hole. In glory-hole mining, the excavation is funnel-shaped, and a vertical passage (raise) driven from below connects with an underground haulage level. The ore slides down this passage into the haulage level for removal.

e. Military Considerations. The ability of any nation to support a war depends upon its mineral resources and enemy mines are accordingly a major objective for air attack. The seizure or defense of important mines may also be the mission of troop units of any size. Mines provide concealment and cover, but their use as shelter for troops may be hazardous and is seldom practicable. Most mines will not withstand the effects of heavy surface bombardment. Coal mines are especially unsuitable for troops or storage. Coal is structurally unstable

and requires extensive supports even in ordinary mining operations. Many varieties of coal give off a gas known as fire damp or marsh gas. This is highly flammable and highly explosive when mixed with air. Coal dust and air also form an explosive mixture. Some mines, particularly salt mines, may be utilized for the storage of supplies and equipment. Adit mines, with their horizontal or slightly inclined entries, are more suitable than vertical-shaft mines for underground storage. The latter type may present drainage problems and offers more difficulties in transporting loads into and out of the mine. To prevent their use by the enemy, mines can be flooded or destroyed with explosives. The possibility of mines being used as headquarters for guerrillas must be considered, and inactive mines in a tactical area should be blocked, destroyed, or otherwise secured against occupancy.

110. Information Requirements — Mines

The information about a mine required for a terrain study will depend upon the purpose. Such information as the following usually is required:

a. Location and name of mine.

b. Product (Mineral extracted, quality, quantity, underground and in reserves).

c. Extraction methods (deep, placer, strip, special methods).

d. Details of layout and operation.

(1) Pits, shafts, galleries, wells.

(2) Hand and mechanical labor involved.

(3) Above ground structures, plant, and equipment.

(4) Refining processes.

(5) Storage facilities.

(6) Transportation facilities.

(7) Utilities (ventilation, electric power, lighting, water, firefighting).

e. Physical condition of installations and equipment.

f. Safety and security features.

g. Availability of labor.

h. Any major repairs needed for operation.

i. Access road and turn around availability.

111. Quarries and Pits

a. Quarries. A quarry is a site providing rock that is suitable in quality, quantity, and size for construction purposes. A hardrock quarry furnishes rock such as granite, limestone, or sandstone, which must be drilled and blasted in quarrying and which must be crushed for some uses. Igneous and metamorphic rocks are generally considered hard rocks. A soft-rock quarry furnishes material that can be removed readily by earthmoving equipment. Soft coral, caliche, shale, chalk, and tuff are materials of this type. Sedimentary rocks are generally considered soft. Quarries are generally the open-faced type, with the vertical surface of the rock exposed. Depending upon local conditions, they may be developed by the single or multiple bench method. A single-bench quarry has the entire floor on one level, the height of the bench worked in one operation varying from 2 to 30 meters (8 to 100 feet). A multiple-bench quarry is one having a series of ledges or terraces resembling steps.

b. Pits. A pit is a site where earth or rock particles suitable for engineer construction may be obtained in quantity. A borrow pit is a site providing soil suitable for fills, surfacing, or blending that can be removed with earthmoving equipment. A gravel pit consists predominantly of particles of gravel size. Unsorted gravel from pits is used extensively for surfacing secondary roads, in base courses for pavements for roads, taxiways, and runways, and as aggregate in concrete and bituminous operations. An alluvial gravel pit derives its name from the origin of the deposit, since the material is stream-deposited. The gravel obtained from these pits usually is very clean and free from clay and humus. It is therefore particularly desirable for concrete and bituminous work. A bank or hill gravel pit produces a clayey gravel or clayey sandy gravel. These materials are very desirable for surfacing work because of their binding qualities.

c. Military Considerations. Pits and quarries are important chiefly as sources of materials for engineering construction. They may be local objectives in tactical operations, if plans require extensive engineering development of

the area. Individual pits and quarries usually can be bypassed by advancing forces, but an area containing a number of them may present difficulties to the movement of larger units and will tend to analyze movements. Flooded quarries are a particularly hazardous obstacle. Pits and quarries provide a varying degree of cover for troops. They may also furnish defiladed locations for artillery and missile positions.

112. Information Requirements — Quarries and Pits

a. Quarries.

(1) Location.

(2) Nature of stone.

(3) Actual and potential capacity in uncrushed stone.

(4) Capacity of crushing machinery in stone of various sizes.

(5) Details of machinery.

(6) Loading facilities

(7) Amount of crushed stone that can be hauled away in a day, considering the manner of loading, number of trucks that can be loaded at one time, access road, and turnarounds.

b. Pits.

(1) Location.

(2) Nature of source.

(3) Nature of raw materials; quality, quantity.

(4) Amount, depth, and type of overburden.

(5) Drainage; ground-water level; standing water.

(6) Utilities available (electricity, water).

(7) Equipment available.

(8) Method of extraction (hand labor, machinery, dredging).

(9) Method of cleaning and sorting.

(10) Daily production capacity.

(11) Transportation routes; access roads; surfaces of roads.

Section V. AIRFIELDS

113. Size, Form, and Components

a. Description. Airfields range in size and function from short landing strips consisting of little more than a cleared area suitable for light liaison planes or helicopters to large permanent air bases with many complex supporting installations. The simplest form of operational airfield consists essentially of a runway, usually oriented in the direction of prevailing winds; one or more perimeter taxiways, with warmup aprons located where they join the ends of the runway; and hardstands to accommodate one or more groups of aircraft. The runway may or may not be surfaced. In addition, there will be a minimum of other facilities, such as access and service roads, fuel storage, ordnance storage, and a control tower. The particular characteristics will depend upon the type of aircraft that will use the field.

b. Tactical Airfield. A tactical airfield in a theater of operations includes the following major elements:

(1) Landing strips.

(2) A system of hardstands and runways.

(3) Warmup aprons close to one or both ends of the runway.

(4) Operation facilities, including control tower and operations and briefing rooms.

(5) Fuel storage and dispensing facilities.

(6) Ammunition storage facilities.

(7) General supply storage facilities.

(8) Repair and maintenance facilities for aircraft, accessories, and automotive vehicles.

(9) Roads, walkways, communications, firefighting unit, and other service facilities.

(10) Security and safety installations.

114. Terrain

a. Location. The general location of a pro-

posed airfield is indicated by the Air Force commander or the Army aviation officer, as appropriate, while the exact site is chosen in coordination with the engineer after a careful evaluation of the terrain.

b. Selection. In selecting a site, the following factors should be considered:

(1) Adequate dimensions to meet operational requirements, with room for future expansion.

(2) Accessibility to supply routes and communication facilities.

(3) Obstructions along flightways and approaches, including critical topographical features, such as high hills or mountains. High tension wires, roads, and railroads crossing the flight way near the runway are dangerous mental and physical hazards to pilots.

(4) Meteorological conditions (wind, rainfall, fog, snow, frost action).

(5) Drainage.

(6) Topography. A site with favorable topography is one located on high ground with sufficient slope for natural cross drainage as well as longitudinal drainage and a reasonably smooth surface requiring little earthmoving.

(7) Clearing, grubbing, and stripping required. A large open area surrounded by sufficient covered areas to conceal all activities is ideal. Ground cover in areas adjacent to the flight strip is especially desirable to provide natural concealment for parked aircraft, dumps, and bivouac and other installations.

(8) Soil characteristics. The type of soil determines the type of equipment required for construction, drainage, effects of adverse weather, and the subgrade bearing capacity that can be obtained.

(9) Availability of gravel, sand, coral, or other materials for excavation.

(10) Water supply. Large quantities of water are required in both the construction and operation of airfields.

(11) Camouflage requirements. A desirable site is one that avoids identifying landmarks and affords cover for installations and aircraft at dispersed locations.

115. Information Requirements — Airfields

Based on available reports and files, detailed studies of particular airfields in local areas will be prepared by intelligence personnel. Pertinent information to be included in a terrain study should include the following:

a. Location (map coordinates, elevation, distance and direction from nearest city or town, principal landmarks, name if any).

b. Category (emergency landing strip, refueling and rearming strip, fighter field, bomber field, heliport, and civilian secondary airport).

c. Characteristics of site (type of terrain, character of soils, special aspects of weather and terrain differing from country-wide or regional conditions).

d. Detailed layout (sketch) of runways, taxiways, parking and service areas.

e. Runways.

(1) Identification.

(2) Length of runway and overrun; extensibility.

(3) Width of runway, overrun, shoulders.

(4) Type and depth of surfacing and base.

(5) Type and adequacy of drainage (ditches, subsurface drains).

(6) Load capacity (in pounds, or kilograms or aircraft type).

(7) Gradient.

(8) Present condition.

f. Taxiways and parking (dimensions, type and depth of surface material and base, load capacity, condition).

g. Detailed description of operation area; improvements planned or under construction.

h. Facilities.

(1) Buildings (type, material, dimensions).
(2) Maintenance and repair (number and extent of buildings and numbers and types of equipment used for airfield maintenance.
(3) Fueling (number and capacity of tanks, above or below ground).
(4) Electricity supply.
(5) Water supply.

i. Related transportation (railroad, road, water; details about type, location, and capacities of transportation facilities available).

j. Airfield construction sites.
(1) Topography.
(2) Wind (direction, intensity of prevailing wind; local peculiarities).
(3) Rainfall (average by months; wet seasons; intensity, duration, and frequency of rainfall).
(4) Other aspects (temperature variations, storms, fog, and ground haze).
(5) Availability of local construction materials.
(6) Water supply.
(7) Clearing and grading required.
(8) Drainage conditions and required improvements.
(9) Soil classification.
(10) Flight obstructions.
(11) Frost heaving, permafrost, flooding, extremely strong winds bear directly on airfield site construction and maintenance.

Section VI. WATER TERMINALS

116. Ports

Water terminals (ports) may range in size from beaches suitable only for landing craft to giant complexes extending along many miles of coastline. They usually constitute key terrain features and primary objectives in military operations. FM 55–51 gives detailed information about the organization and operations of water terminals. Normally, major water terminals (fig. 49) are characterized by deep harbors protected from storms and free from ice in the winter months. The rail and road networks of the area usually extend from the terminals inland to developed portions of the country. Large terminals are often surrounded by commercial, industrial, and shipbuilding areas.

117. Military Significance

a. Vulnerability. Large water terminals are highly vulnerable to attack by nuclear weapons. When the enemy has a nuclear weapon capability, logistical support is provided through a number of dispersed small terminals, often little more than beaches developed to meet minimum requirements. Terrain studies should include an evaluation of all suitable locations for such terminals, indicating their physical characteristics, relative usefulness, and estimated capacities. A large-scale amphibious operation may include a number of separate secondary landings to secure beaches that are suitable for dispersed logistical terminals.

b. Evaluation. Information about established water terminals usually is contained in terrain studies prepared at the highest echelons, which form the basis for studies used in specific operations. The existing water terminals are evaluated as to their usefulness and their present physical condition. If an enemy-held terminal is to be used by friendly forces after its seizure, particular attention is given to the essential structures and facilities that should be spared from destruction, if practicable, during the preliminary bombardment and assault.

118. Information Requirements — Water Terminals

The information about a water terminal which is most essential in preparing a terrain study will depend upon the features that are of the greatest concern in a specific operation. Detailed information requirements for water terminals are contained in FM 55–8. Information required may include—

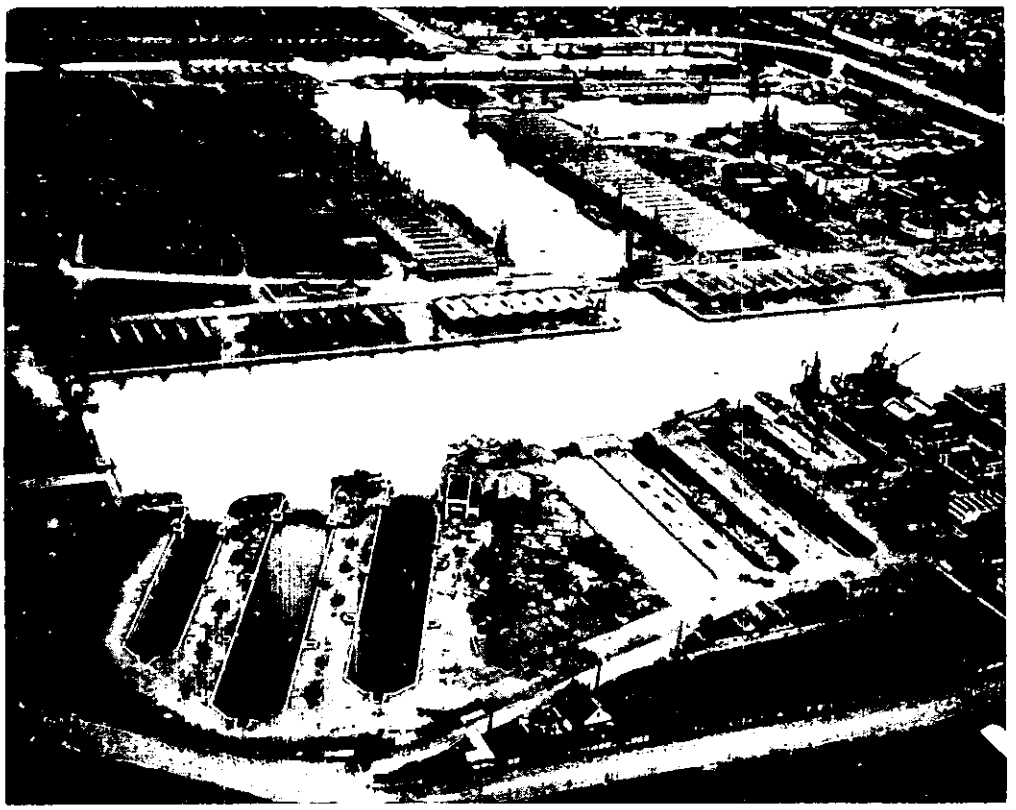

Figure 49. Typical large water terminal (port).

a. Name, location by map references and coordinates.

b. General characteristics (open roadstead, partly inclosed bay, landlocked harbor, sheltered area behind a barrier reef, and river).

c. Entrance and approach channels (controlling depth, length, width).

d. Breakwaters (position, length, construction).

e. Description of harbor.

(1) Type.

(2) Harbor and channel depths.

(3) Extent of silting.

(4) Nature and frequency of maintenance dredging.

(5) Location and nature of anchorages.

(6) Underwater obstructions.

(7) Pilotage information.

f. Bridges regarded as shipping obstructions (location, type, horizontal and vertical clearances at mean low water).

g. Hydrographic and weather conditions.

h. Adjacent beaches usable by landing craft (location, length, type, gradient, and accessibility).

i. Cargo-handling facilities.

(1) Wharves, piers, and quays (type, function, structural features, cargo-handling machinery, road and railroad connections, utilities, mooring facilities).

(2) Wet docks and semitidal basins.

(3) Mechanical handling facilities.

(4) Harbor-service craft (type, function, number).

j. Repair facilities.

(1) Repair yards.

(2) Graving docks.

(3) Floating docks.

(4) Marine railways.

k. Storage facilities.

(1) Location, type of commodities stored, type of constructions, capacity, transportation connections, fire protection, special handling equipment.

(2) Cold storage facilities (temperature, daily ice making capacity).

(3) Grain storage facilities.

(4) Bulk liquid storage (capacities in barrels).

(5) Open storage (location of suitable areas, rail and road connections, approximate capacity).

(6) Petroleum and coal storage (location, type, capacity, bunkering facilities).

(7) Special storage facilities for explosives and ammunition.

l. Clearance facilities (rail lines, highways, inland waterways, pipe lines).

m. Water supply (availability, quality, method and rate of supply).

n. Electric power and lighting (availability, source, and characteristics of current).

o. Capacity of the terminal as a whole, under both normal and present conditions.

p. Data needed for major repairs and improvements; vacant areas available for expansion.

q. Availability of trained, reliable personnel.

Section VII. HYDRAULIC STRUCTURES

119. Types

a. Flood Control. The principal structure employed in flood control is the artificial levee, an embankment built along a river course to prevent flooding of the adjacent country during high water. It may be 6 meters (20 feet) or more in height, and usually is made by packing layers of earth upon a foundation, with grass planted on top of the levee to hold the soil. The levee may be faced with concrete. Usually an artificial levee is constructed some feet in rear of the river banks to provide a wider channel during flood periods.

b. Dams. Earth dams for reservoirs frequently are built of layers of homogeneous material with a center core of puddled clay or other impermeable material. Usually the inner surface is paved with stone or concrete as a precaution against erosion, and the outer surface is covered with grass to bind the surface and to protect it against the weather. Dams across rivers and deep ravines, or where there is considerable width and height, usually are made of stone masonry or concrete. They are built either straight across the river or in the form of an arc, the convex side fronting the stream (fig. 50).

c. Reservoirs. A reservoir is a wholly or partly artificial lake used for water storage. Types of reservoirs include those for flood control, irrigation, recreation, power production, and navigation. Reservoirs are utilized for municipal water supply systems, on rivers to aid in flood control, on canals to maintain the water level for navigation, and in hydroelectric installations to insure a constant water supply. The reservoir may have a lining of clay or other impervious material to prevent water seepage. The embankments or retaining walls may be of earth, loose rock, or masonry. Distributing reservoirs in municipal water systems sometimes are built of masonry or reinforced concrete. They serve to take care of fluctuations in demand and as a reserve in case of interruptions at the source. In reservoirs with earth embankments, overflow is provided for by a *waste weir* or canal, to carry off sur-

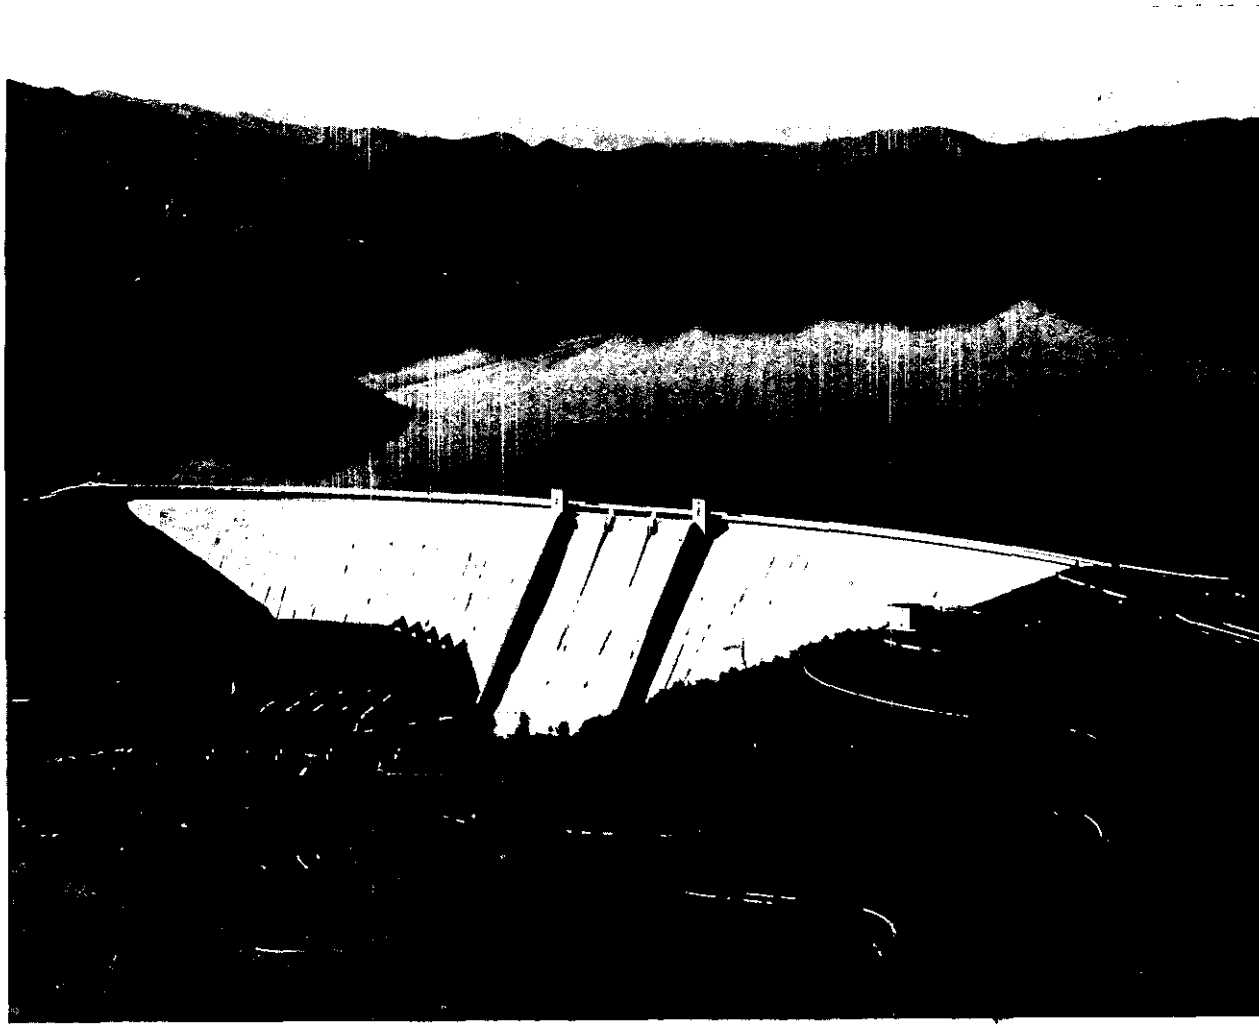

Figure 50. Downstream face of Shasta Dam (California).

plus water. When the reservoir is formed by a masonry dam across a river, the surplus water may be allowed to flow over the top, or spillways may be provided (fig. 51).

d. Locks. The dominant feature of developed waterways is the canal lock. A lock is an enclosed stretch of water with a gate at each end used to raise or lower vessels from one water level to another. When a vessel is to pass from a low level to a higher one, the water in the lock is lowered until it is level with that in which the ship is floating. The vessel is moved into the lock and the gate is closed. Water is then allowed to enter the lock until it reaches the higher level, and then the gate at the other end is opened and the vessel passes through. This procedure is reversed when the vessel goes from a higher to a lower level. Many locks have an intermediate set of gates so that only part of the lock is used for smaller vessels. Usually the water passes through culverts built into the lock walls and is controlled by sluice gates powered by hydraulic or electric power. Lock gates are made of either steel or wood. A pair of gates meets in the center of the lock entrance. When closed, the gates form an arc with the convex side toward the pressure of the water. The lift of a canal lock may be 12 meters (40 feet) or more.

e. Polders. Areas with an extensive network of canals, drainage ditches, and levees may create a major problem in operations. The most notable of these areas are the polders of Belgium and The Netherlands, which have

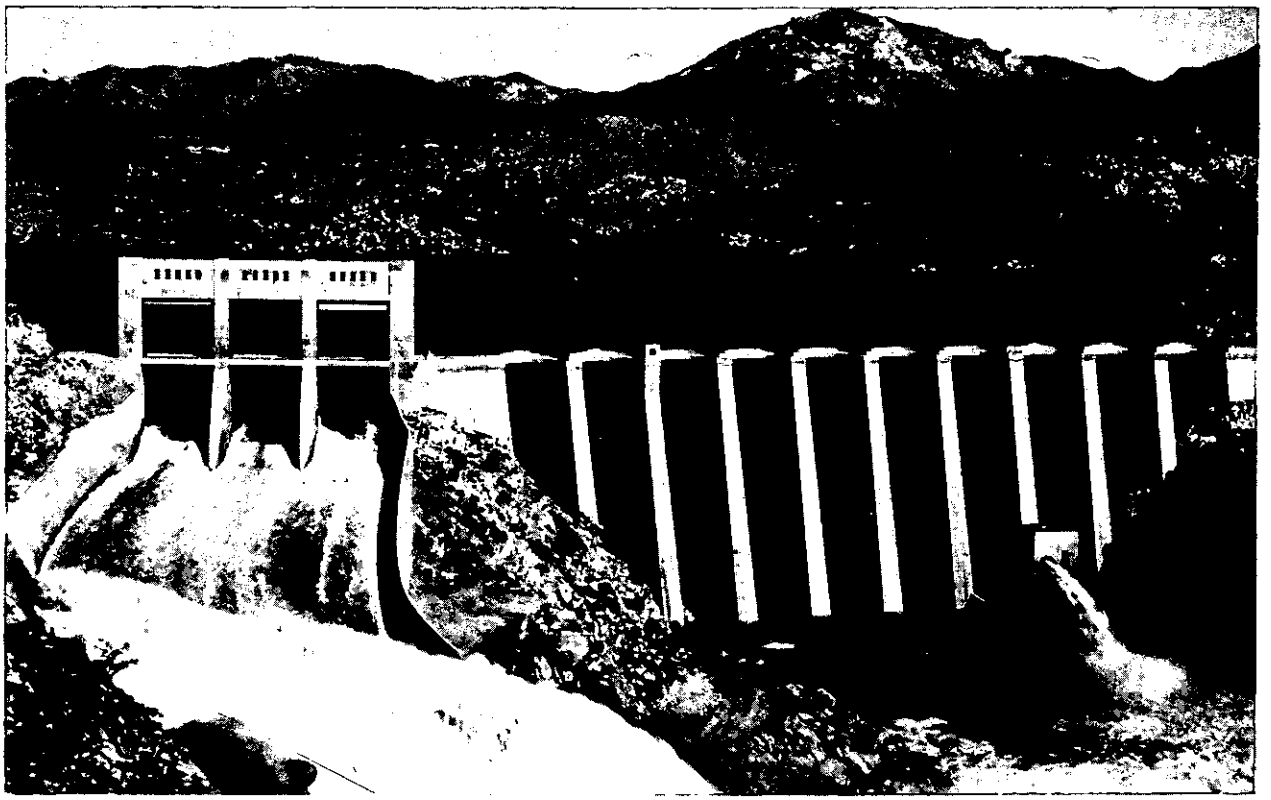

Figure 51. Spillway, storage dam (Bartlett Dam, Arizona).

been reclaimed from the sea by artificial levees called dikes. The terrain is traversed by numerous canals and basins that drain the excess water and serve as navigation routes. The surplus water empties into the sea at low tide. In places where the water courses lead from the interior to the sea, they may be caused to overflow, creating a practically impassable obstacle to movement. In the interior, the polders greatly limit the landing areas suitable for airborne and airmobile forces. When the dikes are destroyed, the cultivated areas are inundated. In these areas tanks and vehicles bog down, there is no cover for infantry, and the water is too shallow for boats.

120. Military Importance

The military importance of hydraulic structures arises from the extensive flooding that may be caused by their destruction. Vast areas may be inundated by the destruction of a large dam or the artificial levees along a major river. Releasing the waters of even a small dam may flood sections of roads and railways or increase the width and velocity of a stream so that crossing operations are impeded. Hydraulic structures in enemy territory may be destroyed by aerial bombardment so as to cause these effects, so they may be seized by airborne forces before the enemy can demolish them. Hydraulic structures are vulnerable to sabotage and guerrilla action. Those in territory under friendly control must be carefully guarded and subject to strict security precautions.

121. Information Requirements — Hydraulic Structures

The type of information that is required concerning a particular hydraulic structure will depend upon whether plans call for its defense, seizure, destruction, or reconstruction. Usually technical specialists are employed to prepare detailed studies of each structure that is being considered. In general, basic information includes—

a. Location and name.

b. Function: navigation, power, flood control, irrigation, water supply.

c. Construction features: design type, materials, height, width, mechanical equipment, capacity.

d. Extent and nature of repairs necessary.

e. Security requirements.

f. Effects of destruction upon the surrounding area.

Section VIII. URBAN AREAS AND BUILDINGS

122. Urban Areas

a. Description. An urban area is defined as a concentration of structures, facilities, and population which forms the economic and cultural focus for some larger area. Usually the inhabitants do not depend upon agricultural activities for their basic economy. A city or town may have a number of functions that make it significant. It may be primarily industrial, commercial, or recreational; the headquarters of government institutions; a port or railway center; or the location of an important cultural feature, such as a cathedral, university, or historical landmark. A large urban area usually has a metropolitan area that includes various surrounding settlements or suburbs whose daily economic and social life is connected with or influenced by the city. Intelligence concerning an urban area covers its general description and importance; physical characteristics; external communication; services and utilities; and major industries, including storage facilities.

b. Topography. The topography and geology of the urban area and its environs are significant elements in the terrain study. Topography exerts a major influence upon the size and pattern of the populated area; the location of external communications; the possibility of inundation or other natural disaster; and the defense that can be made against possible land, waterborne, and air attacks. The development pattern of an urban area is the physical adjustment of the area to its topography, as influenced by past events, current economic forces, and social trends.

c. Construction. The elements comprising an urban area may be classified according to the predominant construction and function of the buildings and other structures. Where no gaps exist between buildings, as in the business districts of larger towns and cities, this is described as block type construction. Detached and semi-detached building areas are those where the buildings are spaced relatively close together, as they are in low- and middle-cost housing areas. Isolated housing areas are found on the approaches to towns and cities where individual or small groups of homes are located in the midst of large open areas. This is typical of the suburbs of the average city.

d. Functional Areas. Normally a city includes separate areas largely devoted to one type of use. The major functional areas may be distinguished as follows:

(1) Industrial areas comprise a grouping of individual plants and loft buildings, with associated storage and transportation facilities, devoted to manufacturing activities.

(2) Commercial areas are composed of a concentration of retail and wholesale establishments, financial institutions, office buildings, hotels, garages, public buildings, and light manufacturing plants.

(3) Residential areas consist predominantly of dwellings with interspersed shopping centers; churches; schools; and fire, police, telephone, and power stations.

(4) Transportation and storage areas contain the terminal, transshipment, storage and repair facilities and service buildings associated with general movement by rail, water, road, pipeline, or railway.

(5) Governmental-institutional areas include the grounds, structures, and facilities related to governmental administrative offices, hospitals, schools, colleges, homes for the aged or orphans, sanitariums, monasteries, penal or research institutions and similar establishments which usually

form distinctive and generally extensive areas.

(6) Military areas contain structures and facilities for billeting, quartering, defense, hospitalization, storage, and repair, which are devoted exclusively to military use.

(7) Open areas comprise land not occupied by buildings and not assigned to any industrial, transportation, business or residential activity. Developed open areas include cultivated land, parks, recreation areas, and cemeteries. Undeveloped open areas include swamps, woods, beaches, and other vacant land.

123. Military Considerations

a. Use of Urban Area. The decision to bypass or to seize and occupy an urban area depends upon the mission of the unit concerned. Cities and towns may be important objectives because they represent centers of population, transportation, manufacture, and supply. Port cities and railroad centers are given a priority status as targets and objectives in both tactical and strategical planning. Unless the mission requires otherwise, a city or town usually is bypassed and isolated, since it is an obstacle that canalizes and impedes both attacking and counterattacking forces. Urban areas are vulnerable to destruction by air or artillery bombardment and may be neutralized by chemical, biological, or radiological contamination. Fires started by nuclear weapons or incendiaries may make them untenable. Combat within built-up areas is described in detail in FM 31–50.

b. Limited Observation and Fields of Fire. Because the opposing troops usually are close to each other, effective close support by artillery and combat aviation is limited. The available cover is rigid and set in straight lines, so that all movement in the open usually can be observed unless it is concealed by smoke, dust, or darkness. Smoke may be used to provide concealment, limit observation, and achieve deception and surprise. In a built-up area, smoke remains effective longer than in open areas. It is usually difficult to observe and locate enemy weapon positions because of the dust caused by the impact of projectiles and explosive charges and the smoke from explosions and fires.

c. Increased Cover and Concealment. Weapons and troops may be concealed in built-up areas, and ample cover is usually available against small-arms fire. Cover from air and artillery bombardment, however, is provided only in buildings of particularly substantial construction.

d. Movement. The mobility and maneuverability of infantry, artillery, and armor are greatly limited in built-up areas. Vehicular traffic is canalized, and extremely vulnerable to ambush and the close-range direct fires of enemy weapons.

e. Communications. It is difficult to maintain efficient communications in built-up areas. Normally control must be decentralized to small-unit commanders. Tall buildings and those with steel frames may interfere with radio communication. Reliance usually must be placed upon wire and foot messengers.

f. Attack. Detailed information concerning the enemy, his defenses, the terrain surrounding the urban area that is under his control, and the layout of the built-up area is essential to the commander in making plans and decisions for an attack. Particular emphasis is placed upon determining the location of covered approaches to the urban area, the location of public utility plants and their security measures and the location and nature of all obstacles. The objective of the attacking force is to seize the entire urban area. Within the area the objectives for individual units include key installations such as railroad stations, telephone exchanges, and the public utility plants, which are often organized as centers of enemy resistance. The attack on an urban area begins with the seizure or terrain features which dominate approaches to the city, followed by the seizure of buildings on the near edge to reduce or eliminate the defender's observation and direct fire upon the approaches. The last phase is a systematic advance through the area until it is fully secured.

g. Defense. Urban areas favor the defense. Whether or not a city or town is organized for

defense depends upon its size, relation to the general defensive position, and the amount of cover it offers for occupying forces. Cities, towns, and villages constructed of flammable materials provide little protection and may become a hazard to the defender, and buildings of solid masonry can be developed into well-fortified defensive positions or centers of resistance. Cellars, sewers, subway tunnels, thick masonry walls, and reinforced concrete floors and roofs provide cover for the defender during heavy bombardments. A heavy aerial or artillery bombardment of a city before an attack actually may serve to strengthen its defenses. The fallen rubble may give the defender increased protection, and may make the streets impassable for armor.

124. Information Requirements—Urban Areas

Information about an urban area requires the compilation of many factors, each devoted to a particular aspect of the area, such as the transportation services, utilities, billeting facilities, or industries. A terrain study should include annotated maps, plans, and photographs, with an accompanying text giving that which cannot be shown graphically. Information that should be included under each category is outlined below. The scope of the information that is presented is limited by the purpose for which the study is being prepared. The text should include information in the following categories, as pertinent:

a. Description.

(1) Name and location (geographic and grid coordinates).

(2) Population (number and trend, significant ethnic and religious segments).

(3) Principal function (communications and industry).

b. Physical Characteristics.

(1) Topography and geology of area and environs.

(2) General cross-country movement of environs.

(3) Climate (mean temperatures and rainfall).

(4) Landmarks (natural and manmade).

(5) Extent of built-up areas (present boundaries, recent additions, probable future expansion).

(6) Functional areas.

c. Structures.

(1) Characteristics of predominant types of buildings (height, number of stories, principal construction materials).

(2) Structure density (ratio of roof coverage to gross ground area; as warranted, ratio of roof coverage to ground area within each of the functional areas).

(3) Principal buildings.

d. Susceptibility to Fire and Shock.

e. Damaged or Destroyed Areas (delineation and general character).

f. Significant Ethnic and Religious Groupings (delineation and general character of the areas occupied).

g. Streets.

(1) Surface, condition, and pattern.

(2) Prevailing widths (to curb and building to building).

(3) Names and alinement of through routes and principal streets.

(4) Location and characteristics of bridges, tunnels, and ferries.

h. External Communications.

(1) *Roads.* Identification of the roads that enter the urban area, the routes that bypass it, and the road distances to the nearest important town on each route should be shown on maps. In the text, the importance of the roads as avenues of movement to and from the town should be discussed. Annotations on city maps should locate and identify highway structures, ferries, and road service facilities.

(2) *Railways.* Maps should show the railways that enter or bypass the urban area, with distances to the nearest

important towns. Text should discuss the importance of the railways as transportation arteries. Annotations on city maps should locate and identify railway structures and crossings (bridges, tunnels, and ferries) and such railway structures as passenger and freight stations, yards and sidings, repair shops, turntables, and "y" track.

(3) *Inland waterways.* Identification of each navigable water route (river, lake or canal) which borders or passes through the urban area and the waterway distance to the nearest upstream or downstream port should appear on maps. The importance of the waterway should be discussed in the text. Annotations on city maps should locate and identify important waterway structures. Information on shipyards is included with that on the industries of the urban area.

(4) *Airfields.* The location of each airfield and seaplane station which serves the urban area should be shown on city maps or, if beyond the limits of the city, on topographic maps. Text should indicate the adequacy of the existing air service, list each commercial airline which serves the area, and provide information on the frequency of service. Information about airfield classification is presented in TM 5–330.

i. Urban Services and Facilities.

(1) Water supply.
- (*a*) Sources (name, location, type, capacity).
- (*b*) Treatment plants (number, type, capacity, and location).
- (*c*) Storage (name, location, type, capacity).
- (*d*) Method of distribution.
- (*e*) Consumption (in terms of minimum and average requirements per person per day, whether any rationing is practiced and during what periods, annual consumption).

(2) Sewage disposal (sanitary, storm, industrial waste).
- (*a*) Collection methods (type, adequacy).
- (*b*) Treatment plants (type, location).
- (*c*) Disposal methods (including location of dumps or incinerating plants).

(3) Garbage and trash disposal.
- (*a*) Collection methods.
- (*b*) Treatment plants (type, location).
- (*c*) Disposal methods (including location of dumps, incinerators, and processing plants producing fertilizer).

(4) Major hospitals.
- (*a*) Name, location, and specialization, if any.
- (*b*) Bed capacity.
- (*c*) Age and condition.

(5) Electricity.
- (*a*) Sources (name, type, location, installed capacity).
- (*b*) Substations (name, type, location, capacity).
- (*c*) Distribution current characteristics.
- (*d*) Number of consumers.
- (*e*) Yearly consumption.

(6) Gas.
- (*a*) Type.
- (*b*) Sources (name, location, capacity).
- (*c*) Storage (type, location, capacity).
- (*d*) Extent of distribution.
- (*e*) Number of consumers.
- (*f*) Yearly consumption.

(7) Storage.
- (*a*) Open (large open areas within or adjoining the town suitable for use as open storage and supply dumps).
- (*b*) Covered (warehouses and sheds).
- (*c*) Cold (refrigerated storage; ice plants with cold-storage facilities).
- (*d*) POL (number of tanks or reservoirs at each location; capacities in U. S. barrels).

(*e*) Explosives (magazine and bulk-storage facilities; types and quantities of explosives stored).

(8) Ice-manufacturing plants (name, location, capacity).

(9) Billeting and accommodation. (Total capacity for billeting and accommodation in military barracks, hotels, public buildings, school and institutional buildings, and other structures; total capacity of bakery and laundry establishments; availability of baths and swimming pools suitable for troop use. Location, capacity, and type of each structure.)

(10) Internal transit system (type, extent, location of main terminal, and maintenance facilities).

(11) Fire protection (organization and manpower of fire department; quantity and type of equipment).

(12) City government (type, personalities, location of facilities).

(13) Civil defense (organization and manpower; quantity and type of equipment).

(14) Industry.

(*a*) Major industrial activity (for each industry, the type, number of plants, number of employees, and importance).

(*b*) Significant manufacturing plants.

125. Buildings

a. Construction. The design and construction of buildings are influenced by climate, available materials, function, and the cultural development of the native inhabitants. In areas with a tropical climate and primitive agriculture, for example, buildings usually are only crude huts made of woven grass, sticks, and mud. Buildings in desert oases are made of clay with thick walls, so that they are cool in summer and fairly warm in winter. In dry climates, where suitable timber is scarce, a wooden structure is a rarity and buildings are constructed from stone, adobe clay, or turf. Where there are cold winters, buildings will be solidly constructed of stone and wood.

b. Military Considerations. The military significance of a building or group of buildings depends upon the purposes of the study. A building may have value as an obstacle, a defensive strongpoint, or as a possible storage, headquarters, medical, or maintenance installation. The structural features of buildings comprise the predominant materials used, size and height, fire resistance, and architectural design. Brick, stone, and masonry buildings, when demolished, create rubble that may make formidable obstacles, or may provide concealment and cover for troops. Flimsy wooden buildings are highly flammable and may be remunerative targets for incendiary shells and bombs. Since the fires are an obstacle to an attacker, they may be employed as a weapon by the defender. The height and number of stories in a building are significant features when selecting observation points. Buildings used in the community may be adapted for military uses. These include garages and other repair facilities, stadiums, theaters, auditoriums, warehouses, transportation terminals, and schools. Wherever possible, structures of religious or artistic importance are usually designated before an operation by civil affairs/military government agencies, and their employment for military purposes is prohibited. Buildings made of solid masonry, concrete, and steel may be organized into defensive strongpoints. Substantial structures with deep basements provide varying degrees of cover from air or artillery attack. The protection against nuclear effects offered by buildings varies according to the type of construction, flammability, distance from ground zero, and many other factors. Personnel in buildings will be protected from the thermal radiation effects of a nuclear weapon and will receive some degree of protection from nuclear radiation effects. Casualties from secondary blast effects are caused largely by falling walls and ceilings and flying glass.

126. Information Requirements—Buildings

a. Location and function (residence, store, warehouse, factory, school, government headquarters, and communication center).

b. Structural features (materials, founda-

tions, roof, bearing capacity of floors, exits, and basement).

c. Layout and capacity (floor plans, areas, cubages).

d. Utilities.

e. Possible military uses.

f. Security features (estimated capability for withstanding bombardment by conventional and nuclear weapons).

g. Needed repairs or improvements for military use.

127. Utilities

a. Special Studies. Detailed intelligence about the utilities of an urban area is necessary in order to plan its utilization for military purposes. In addition, civil affairs may require specific, detailed information and intelligence for special purposes. Special studies by technical personnel should be prepared covering each of the following:

(1) Water supply.
(2) Sewage disposal.
(3) Electric power.
(4) Illuminating gas.
(5) Public transportation system
(6) Communications.
(7) Fire protection.
(8) Trash and garbage disposal.

b. Use of Special Studies. Intelligence studies covering utilities form the basis for estimating requirements for operating and maintenance personnel, the equipment and replacement parts needed for repairs and operation, and the amount of military equipment that must be provided to supplement the existing utility installations. These studies also furnish a guide to selecting the most profitable targets for air attack. The destruction of key utilities is given a high priority in planning aerial bombardments, since a breakdown in these services results in disorganization of the enemy defenses and is highly damaging to civilian morale.

128. Information Requirements—Utilities

The amount and type of information about the utilities of an urban area that is required will depend upon the purpose for which the area is being considered. If it is intended to develop a city into a major logistical base, complete information concerning the capacity, state of repair, and operating methods of each utility will be nceessary. The capability to supply minimum civilian needs as well as military requirements must be evaluated. General surveys of utilities should include the following information about each service or installation—

a. Physical condition.

b. Adequacy for normal load.

c. Portion of present capacity that could be diverted to military use.

d. Repairs, essential for military utilization.

e. Safety and security provisions.

f. Availability of skilled, reliable, civilian personnel.

g. General efficiency and dependability of the plant or system.

Section IX. NONURBAN AREAS

129. Types

a. Farmstead. Populated areas outside towns and cities usually consist of farmsteads and small settlements. A farmstead is the dwelling and adjacent buildings associated with an individual farm. The characteristics of a farmstead reflect the climate of the area and the type of agriculture.

b. Tropical Climate. In rainy tropical climates, most of the inhabitants dwell along streams and waterways, the settlements being located on the bluffs, which are well-drained and exposed to the river breezes. The large rubber, coconut, or banana plantations are usually near the ocean or on the banks of navigable rivers, since roads and railways are few and difficult to maintain. Nonurban areas in dry subtropical climates are dominated by large cattle and sheep ranches, with individ-

ual farmsteads separated by miles of grazing land. In semiarid tropical climates, the native agriculture is largely pastoral, and the relatively few settlements consists of huts surrounded by mud walls or fences of thorny brush. Subarctic villages seldom consist of more than a dozen dwellings, with as much as 50 to 65 kilometers (30 to 40 miles) between settled areas.

c. Temperate Climate. In temperate climates, the buildings of a farmstead are detached from each other, while in areas with extremely cold winters the house, barn, and other outbuildings commonly are under one roof. The outbuildings of a farmstead in the tropics normally are few and small, because the animals remain outdoors all year. Small villages in the middle latitudes often consist of houses built in rows along the sides of a road or clustered around an open square, and in tropical climates the houses of a village usually are dispersed without any regular pattern.

130. Military Significance

a. In general, the same considerations that are pertinent to an urban area also apply to nonurban areas. Small settlements may be critical when they dominate routes of communication at fords, bridges, railway lines, or defiles (fig. 52). Villages that are small in size may have considerable military significance because of a particular industry, mine, or other unique economic feature. They may be local markets and distribution centers serving a wide area and representing an important enemy source of foodstuffs and other supplies. A village with a small local population may be a resort area or the site of a university or similar large institution, capable of providing quarters and other facilities for large numbers of troops.

b. In tactical operations, it is occasionally necessary to secure or destroy small villages that have no direct military value but are used to provide concealment, supplies, and other support to guerrillas. The civilian inhabitants may have to be relocated in other settlements under military control. The buildings of a farmstead furnish quarters for troops and shelter for storage and maintenance facilities. Stone buildings may be suitable for weapons emplacements and defensive strongpoints. Nearly all rural dwellings are within a short distance of a reliable source of water. Cross-country movement frequently is hampered by obstacles such as stone fences, retaining walls, irrigation ditches, and paddy fields. Features such as high fences, hedgerows, embankments, and ditches may offer limited cover and concealment to individuals and small groups.

131. Information Requirements—Nonurban Areas

The particular information about a farmstead or small village that is required will depend largely upon the mission of the unit concerned. Basic information requirements should include—

a. Location; relation to local terrain features.

b. Size (area, population, pattern of streets or roads).

c. Facilities for quarters, maintenance and repair installations.

d. Predominant construction materials.

e. Utilities.

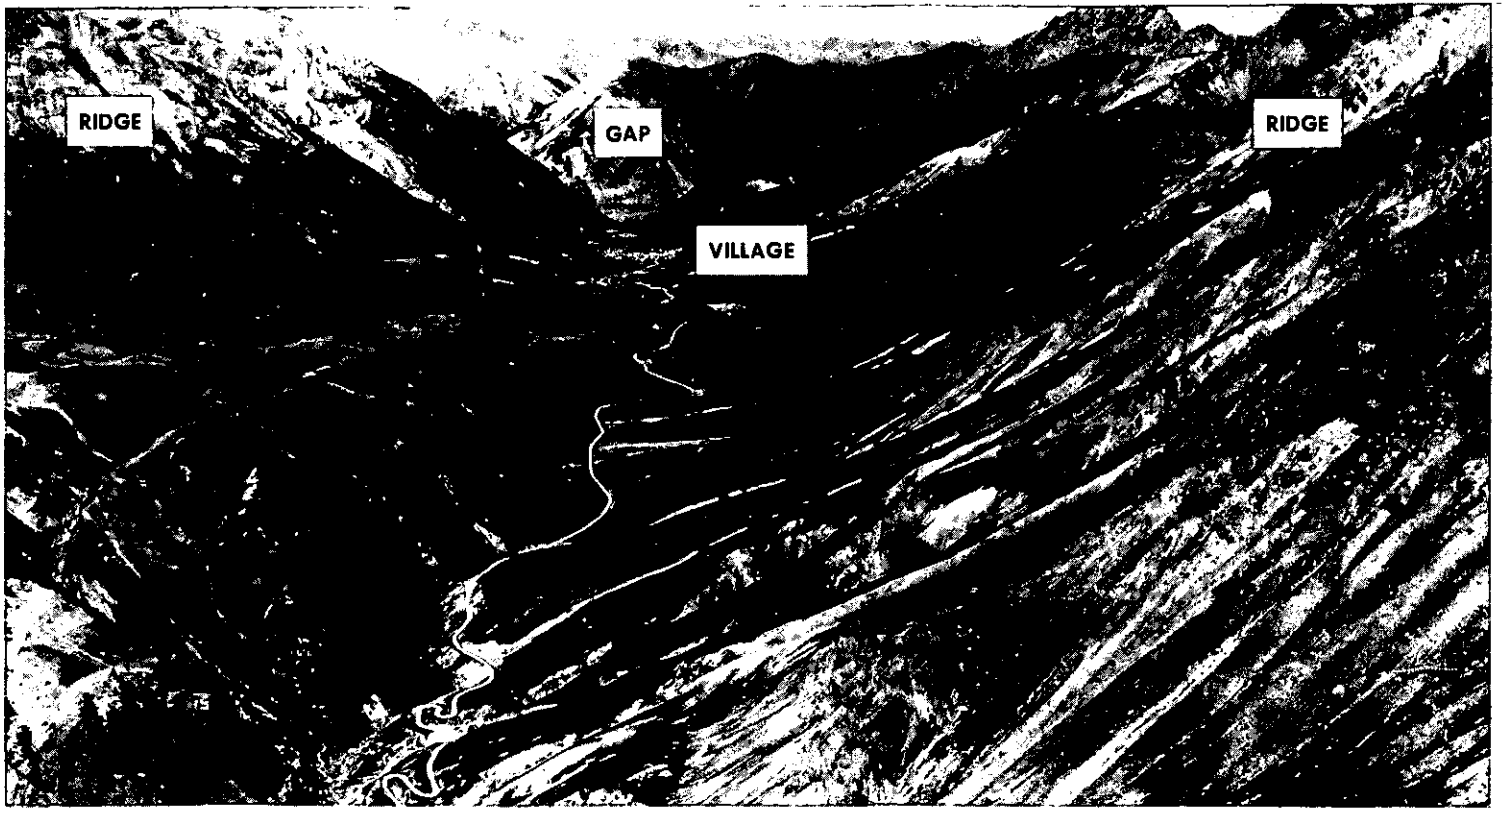

Figure 52. Small settlement dominating a main route of communication.

CHAPTER 7

MILITARY ASPECTS OF THE TERRAIN

Section I. MILITARY USE OF TERRAIN

132. Commander's Considerations

In conducting an operation, the commander must determine how the terrain can be used most effectively by his forces, how it may affect the enemy's capabilities, and how it may be exploited to interfere with the enemy. With the assistance of his staff, he considers the weather conditions, relief and drainage, vegetation, surface materials, and manmade features and their effects upon—

a. Key terrain.

b. Observation and fields of fire.

c. Cover and concealment.

d. Obstacles.

e. Avenues of approach.

f. Communications.

133. Key Terrain

The relative importance of various aspects of the terrain varies with the mission, the type of operation, the size and composition of the forces involved, and their weapons and equipment. Detailed intelligence concerning terrain features normally increases as the size of the unit diminishes. The commander of a field army, for example, may be concerned about the effects that an extensive mountain range will have upon a proposed campaign. A corps commander might be interested only in one mountain of the range, while the commander of a brigade would concentrate upon a particular group of foothills in his area. When making a systematic study of the military aspects of an area, it is sometimes divided into natural subareas, or, if there are no suitable natural boundaries, into subareas based upon the tactical plan. The military aspects of the terrain then are evaluated by each subarea from both the friendly and enemy points of view.

134. Observation and Fields of Fire

a. Observation. Observation is the direct examination of terrain and military activities. It includes examination from ground and air by unaided vision or assisted by optical and infrared devices and detection by photographs, radar, and sonic devices. In general, observation refers to the ability of a force to see the enemy under specified conditions of weather and terrain. The best terrain for observation is that which permits both long-range observation into enemy-held areas and close-in observation of the hostile forward elements. Usually long-range observation is found near the topographical crest and close-in observation is obtained from a location near the military crest. Fog, smoke, precipitation, heat refraction, darkness, manmade and natural features, and vegetation may limit or deny observation. They must be evaluated in determining the extent and type of observation that will be available to enemy and friendly forces. The highest point on the terrain does not always provide the best observation, since variations in relief often create blind spots in the field of vision. The selection of observation points should be based upon reconnaissance, topographic profiles, or examination of aerial photographs.

b. Fields of Fire. A field of fire is an area that a weapon or group of weapons can cover effectively with fire from a given position. The

natural terrain must be evaluated according to its suitability for flat-trajectory weapons, high-trajectory weapons, rockets, and guided missiles, including those with nuclear capabilities. The ideal field of fire for flat-trajectory weapons is flat or gently sloping terrain on which an enemy can be seen with no protection for him within the effective ranges of the waepons. Broken terrain creates dead spots and furnishes cover and concealment for the enemy. Open terrain providing good fields of fire permits a unit to defend a wide front. Broken terrain makes it necessary to provide more troops and weapons to defend a given frontage. The field of fire of high-trajectory weapons is limited only by very steep reverse slopes that the weapons cannot reach and by masks which permit the enemy to occupy positions in defilade. Fields of fire can be improved by cutting or burning vegetation, demolishing buildings, and cutting lanes through woods.

135. Cover and Concealment

a. Evaluation of Terrain. Terrain is evaluated to insure the maximum use of concealment and cover. Terrain under enemy control is also studied, to determine how his concealment and cover can be destroyed. In the attack, concealed and covered routes into the enemy position are sought to gain surprise and to reduce casualties. In the defense, concealment and cover are utilized not only to protect individual positions, but also to hide the general trace of the defenses, so that the attacking troops may be vulnerable to surprise by the location of defense positions and weapons fires. When evaluating terrain for the cover that it will provide, the characteristics of all the weapons used by the enemy must be considered. This includes their ranges, types of fire, and the relative quantities of each type of weapon available to him.

b. Cover. Topography is the major factor influencing cover. Valleys, mountains, gullies, ravines, hills, and similar features provide cover from flat-trajectory weapons. Individuals and small units may secure cover from such terrain features as ditches, riverbanks, folds in the ground, shell craters, buildings, walls, railroad embankments and cuts, and highway fills. Cover from high-angle weapons usually is difficult to obtain. Caves, buildings of exceptionally strong construction, and the steep slopes of hills and mountains may offer some degree of cover, depending upon the capabilities of the weapons employed by the enemy. Nuclear thermal radiation travels by line of sight, so that it will be masked by hills, banks of ravines, and gullies. The extent of protection thus provided will depend upon the height of the explosion. A nuclear blast wave curves around obstacles and is less affected by relief features.

c. Concealment. Terrain features that offer cover also provide concealment. The greater the irregularity of the terrain, the more concealment it will furnish from ground observation. Lower echelons are concerned with the concealment of men, vehicles, weapons, and emplacements; higher echelons, with the concealment of headquarters, supply dumps, airfields, and other major installations.

136. Obstacles

a. Types. According to their effects, obstacles may be classified as antipersonnel obstacles, antimechanized obstacles, underwater obstacles, and obstacles to the landing of aircraft. Natural obstacles comprise such features as unfordable streams, swamps, deep snow, cliffs, steep slopes, thick woods and undergrowth, flooded areas, boulder-strewn areas, lakes, mountains, and nontrafficable soils. Artificial obstacles include those prepared to delay or stop military movement, such as contaminated areas, minefields, trenches, antitank ditches or barriers, roadblocks, blown bridges, road craters, deliberately flooded areas, wire entanglements, and various types of beach and underwater obstacles. They also include man-made features that were not originally designed as obstacles to military movement, such as canals, levees, quarries, or reservoirs.

b. Employment. The employment of obstacles is integrated with the overall scheme of maneuver and fire support. Both natural and artificial obstacles are utilized to channel, direct, restrict, delay, or stop an opposing force. Instructions for the employment of obstacles usually are included as a barrier annex to the operation order of divisions or higher echelons.

FM 31–10 discusses the use of obstacles and the requirements of barrier plans.

c. Barriers. A barrier plan provides for the most effective employment of obstacles to impede enemy movement along favorable routes of approach, divert advancing enemy forces towards routes favorable to defense or compel the enemy to concentrate or disperse. Artificial obstacles must not be located where they would interfere with the proposed movements of friendly forces or with counterattack plans. They may be placed in considerable depth, so as to provide time for counterattacking troops to meet an enemy threat, and to force the enemy to expend time and strength at each barrier. To be fully effective, artificial obstacles must be kept under observation at all times, and must be augmented by fire or explosives. Whenever possible, obstacles are sited so that they are under friendly observation but defiladed from enemy observation. Local unit commanders are responsible for constructing obstacles for the close-in defense of their positions. Advice and technical assistance is provided by engineers, who also construct and install obstacles which require special skill and equipment. The use of toxic chemical and biological agents and radiological contamination to supplement barriers or as obstacles, makes it possible to deny or restrict areas by contamination, to canalize enemy maneuver, or to contaminate enemy field fortifications so that they are untenable. Additional information about the employment of these agents is contained in FM 3–5, FM 21–40, and FM 100–5.

d. Effects. The effects of natural terrain features as obstacles to military movement are discussed in chapter 6. Artificial obstacles are described in FM 5–15 and FM 31–10. The location and extent of both natural and artificial obstacles must be considered by a commander in making his plans. He must decide how they will affect his mission. The tactical effect of an obstacle depends upon the type of operation, the weapons and equipment employed, and the size of the forces involved. A terrain feature that is a major obstacle for a company may be a minor obstacle to a brigade and no obstacle at all to a division.

e. Location. Obstacles may either help or hinder a unit, depending upon their location and nature. For example, a deep creek lying across the axis of advance will slow up an attacker, but will provide defending forces with an advantage, since it delays advancing troops and exposes them to fire. Similarly, heavy woods in front of a position may provide infantry with a concealed route of approach but act as an obstacle to the movement of supporting tanks. In general, obstacles perpendicular to the axis of advance favor a defending force, while those parallel to the axis may give the attacker an advantage by protecting his flanks, although they will also limit lateral movement and his ability to maneuver.

f. Offense. In offensive operations, obstacles influence the choice of objectives, the avenues of approach to an objective, and the time and formation of an attack. Obstacles may be employed to contribute to flank security, impede counterattack, provide additional protection for a section of the front that is not strongly manned, or assist in enemy entrapment.

g. Defense. Obstacles are employed in the defense to channel, direct, delay, or stop the movement of an approaching force. They may be used to delay the initial enemy advance toward the front and flanks of a position, delay the movements of enemy penetrating or enveloping forces, or canalize enemy penetrations into avenues of approach where they can be defeated, or destroyed.

137. Avenues of Approach

a. To a Terrain Feature or an Objective. This is an area of terrain which provides a suitable, relatively easy route of movement for a force of a particular size and type. An avenue of approach should provide—

(1) Ease of movement toward the objective.

(2) Concealment and cover from the defender's observation and fire.

(3) Favorable observation and fields of fire for the attacker.

(4) Adequate maneuver room for the attacking force.

b. Suitability and Ease of Movement. The suitability and ease of movement of an avenue of approach depend upon—

(1) The routes of communication.
(2) Soil trafficability.
(3) Concealment and cover.
(4) Observation and fields of fire.
(5) Obstacles.
(6) Relationship of terrain corridors and cross compartments.

c. Multiple Use. In some types of operations, in which maneuver is very limited by either weather or terrain, an avenue of approach may in itself be a key terrain feature. For example, in rugged mountainous terrain, one road along a valley may be the only route of supply and at the same time the most favorable avenue for approach for the major element of the attacking force. A river in the jungle may be the only transportation route, and thus a key terrain feature, an avenue of approach, and an obstacle.

d. In Attack. Usually an attack is directed toward securing dominating terrain early in the action. The avenue of approach that is most favorable for accomplishing this mission normally is assigned to the forces making the main attack. Whenever possible, the avenues of approach that are selected are those that avoid areas most strongly held by the enemy. In planning an attack, a study is made of the avenues of approach that might be used by the enemy for counterattacks and for reinforcing and supplying his forces. These avenues can be determined by an analysis of the terrain in its relation to the location of enemy reserves and supply routes.

e. In Defense. In planning the organization of defense positions, the terrain is evaluated to determine the avenues of approach that are most likely to be used by the enemy. These normally will be the avenues that lead toward key terrain features, provide good observation, fields of fire, concealment and cover, and either avoid or exploit obstacles. Defense positions are sited to deny such avenues of approach to the enemy. The avenues of approach that can be used by friendly forces in counterattacks also are evaluated.

138. Compartments

The effects of relief and drainage upon avenues of approach are considered in terms of compartments. A terrain compartment is an area bounded on at least two opposite sides by terrain features such as woods, ridges, or villages that limit observation and observed fire into the area from points outside the area. A terrain compartment includes not only the area enclosed but the limiting features as well. Delimiting lines are imaginary lines drawn along limiting features from which ground observetion into a compartment is limited. In compartments formed by woods and villages, these lines run at some point within the edge of the woods or village, depending upon the density of the woods, or the number and density of the buildings. Compartments are classified according to the direction of movement of the forces operating in them. They are termed corridors (fig. 53) when the longer dimension of the compartment lies generally in the direction of movement, or leads toward the objective, and cross compartments (fig. 54) when the longer axis is perpendicular or oblique to the direction of movement. Compartments are also classified as simple or complex (figs. 55 and 56). A complex compartment is one having a smaller compartment or compartments lying within it. This is the type most often encountered.

139. Corridors

Corridors, or ridges that form their limiting features, provide favorable routes of approach for an advancing force because the defender's lateral organization and fields of flat-trajectory fire are obstructed by the limiting features, which also decrease his ability to obtain mutual support between units and limit his observation. To the attacker, a corridor offers two types of approach: valley approach and ridge approach.

a. Valley Approach. Although a valley approach may provide concealment and cover, the military crest of the limiting features on each side must be controlled to deny enemy observation and direct fire into the valley. The best axis of advance is the one that offers the most favorable conditions of observation, cross-country movement, fields of fire, concealment, and cover. Often the most favorable route is along the slopes of a ridge below the military crest rather than along the valley floor. A valley approach should never be used when the enemy controls dominant flank ob-

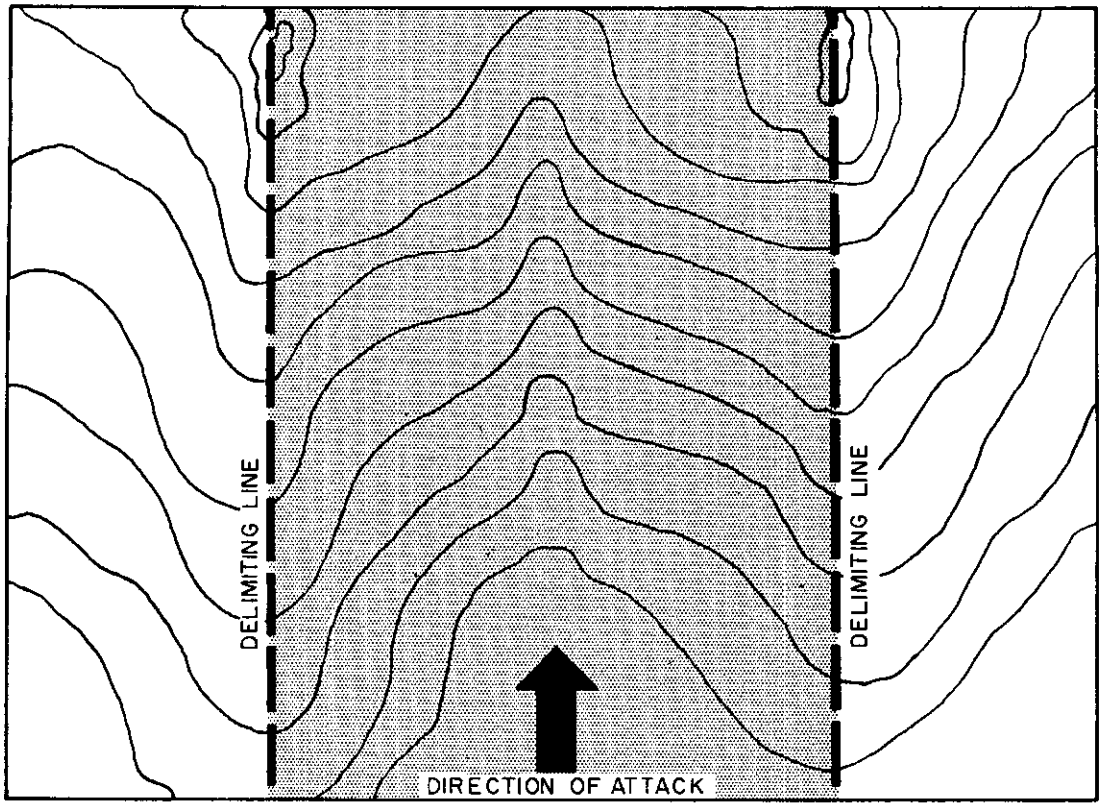

Figure 53. Terrain corridor.

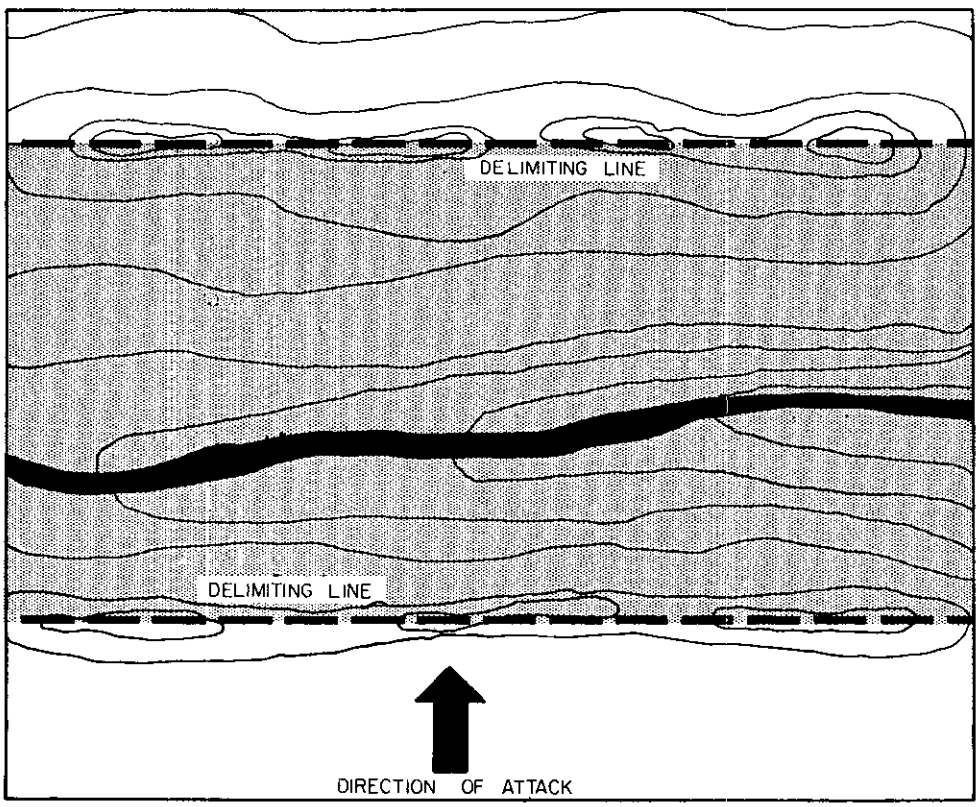

Figure 54. Cross compartment.

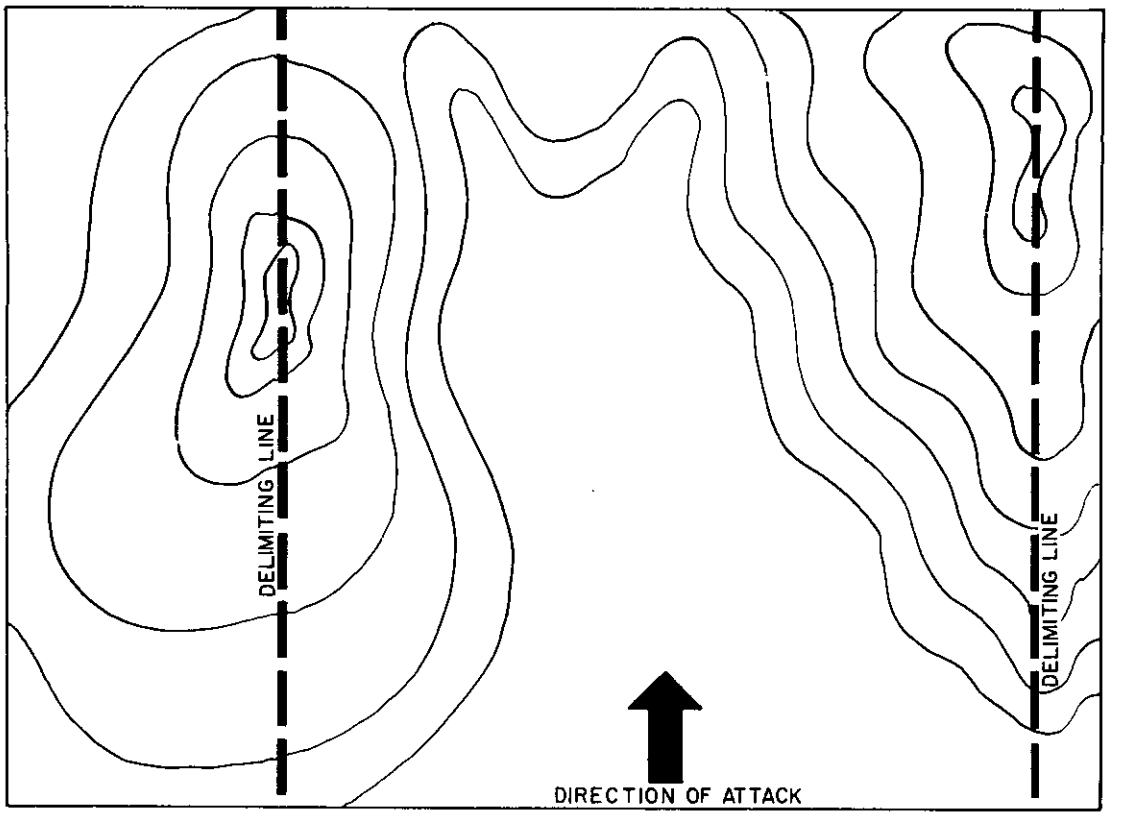

Figure 55. Simple compartment.

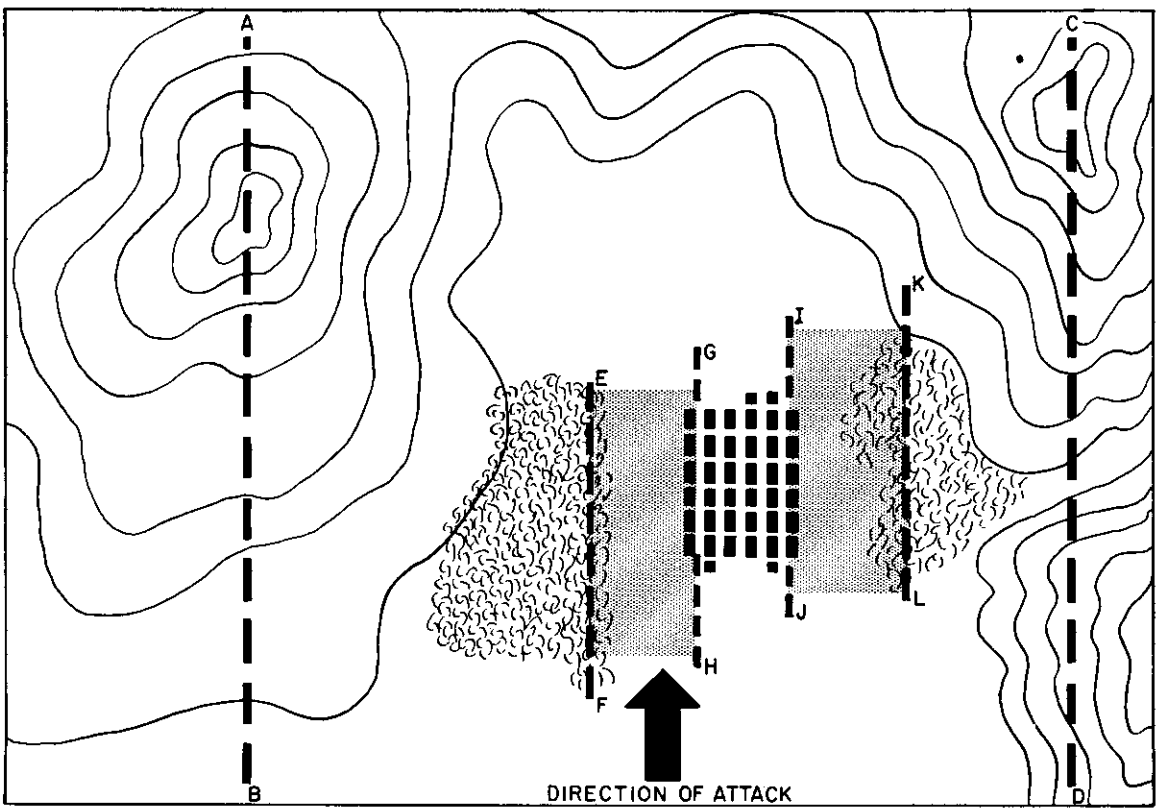

Figure 56. Complex compartments.

servation into the valley, where there are numerous obstacles, and the soils have poor trafficability characteristics.

b. Ridge Approach. The suitability of a ridge for an avenue of approach depends upon its width and shape, the size and frontage of the unit concerned, the distance to adjacent ridges and their elevations, and the capabilities of the enemy weapons. A ridge approach places the axis of advance along dominant observation, but offers little protection from enemy fire directed at the ridge. Usually the best axis of advance in a ridge approach is slightly below the topographical crest, with sufficient forces deployed to control the crest.

c. Cross Compartments. Cross compartments provide the defender with the most favorable terrain for obtaining maximum observation and fields of fire. Mutual support between units, both laterally and in depth, is available and cross compartments also provide the defender with successive defensive or delaying positions. The concealment or cover provided by each limiting feature permits the defender to shift his reserves to meet or to counter threats to his position.

Section II. SPECIAL OPERATIONS

140. Amphibious Operations

a. Detailed Studies. Amphibious operations require detailed studies of hydrography, weather, and terrain. A technical discussion of the requirements and preparation of these studies is beyond the scope of this manual. They are covered in FM 60–30, FM 110–101, and FM 110–115, which also describe the characteristics, tactics, and techniques of amphibious operations. The discussion in this paragraph supplements information in paragraphs 70 through 75.

b. Weather Effects. All phases of an amphibious operation are directly influenced by weather conditions. Weather affects the tides, beaching and unloading conditions, speeds of vessels, air support, and visibility. Poor weather conditions may provide cover for the amphibious force, but favorable weather is essential for the actual landing and during the initial buildup that follows, because excessive sea and swell jeopardize the entire operation.

c. Location. The ideal beach for an amphibious landing is one near a strategic location, with no obstructions seaward; deep water close nearshore; a firm bottom; minimum variation in tides, currents, or surf. The beach terrain should be gently rising, relatively clear, with a firm surface that has adequate drainage. Adequate exits from the beach area should be available. Flat or gently rising terrain, backed by a coastal range high enough to mask the landing area, is the most desirable for landing operations. Ideal conditions are rarely found, and so suitable areas must be evaluated to determine those that come nearest to the optimum requirements.

d. Coastal Plain. A landing on a wide coastal plain provides unrestricted maneuver room usually free from enemy observation and a subsequent advance from the beach can be made in any direction. Boundaries and objectives are hard to locate on this type of terrain, however, and there are few prominent registration points for artillery, naval gunfire, and aerial bombardment. Usually there is no good defensive terrain on the flanks of the beachhead, so that more troops are required to protect the flanks.

e. Coastal Ridge. Terrain which rises evenly to a considerable distance back from the beach gives the defender excellent observation and fields of fire. More commonly, the coastal area remains flat for some distance and then rises abruptly to a coastal ridge.

f. Sand Dunes. Ground that is sharply broken by extensive sand dunes or a low coastal plateau provides the attacker with concealment from enemy observation. The small compartments and corridors limit the range of defensive fires. Direction and control may be extremely difficult.

g. Mountains. Mountains located directly on the sea usually limit the number of beaches large enough to accommodate a landing force of effective size. Where steep ground is lightly defended or neglected by the enemy, a lightly equipped force may seize it and gain surprise. Airborne or airmobile troops may be used to block the movement of enemy reserves to the

landing area, or to secure passes through the mountains and thus prevent the enemy from interfering with the amphibious landing.

141. Airborne-Airmobile Operations

a. Basic Factors. The characteristics, tactics, and techniques of airborne operations are discussed in FM 17–36 and FM 57–10. Airborne forces are capable of crossing such terrain barriers as inland seas, mountains, and jungles that represent serious obstacles to the movement of other troops. Usually airborne assaults are made on terrain that is relatively undefended, to secure initial surprise. Weather has greater restrictive effects upon airborne operations than upon ground operations. Adverse weather may cause postponement or delay in initiating an operation, and prevent adequate reinforcement or supply by air. In addition to terrain studies covering landing and drop-zone areas, special studies may be required to determine the most favorable routes for linkup between airborne forces and friendly ground units.

b. Terrain Requirements. One of the principal factors influencing the selection of a landing area for airborne forces is the terrain. The area chosen must provide adequate space to permit defense in depth; room for maneuver; a safe landing for troops, supplies, and equipment; and protection for critical installations. Airborne troops can land on any terrain that is relatively free from obstacles. Unobstructed areas are required for the landing and recovery of heavy equipment dropped by parachute. Assault aircraft can land on any relatively level and unobstructed terrain that has suitable trafficability. Other fixed-wing transport aircraft require suitable airfields or prepared landing strips. Rotary-wing and other aircraft with vertical takeoff and landing characteristics can land in areas that are otherwise accessible only to parachute units.

c. Drop Areas. The selection of drop areas for the delivery of supplies by parachute requires a consideration of the following:

(1) *Length.* The required length of the area depends upon the type of plane being used. Normally an area 460 meters (500 yards) long is a minimum requirement.

(2) *Width.* A width of 180 meters (200 yards) is minimum. The pilot must have a reasonable amount of room so that he may fly to the right or left of the center of the area, allowing for the drift of his plane under the influence of surface winds.

(3) *Surface conditions.* The type of soil must be considered in relation to the effect that it will have upon the falling loads. A hard surface may cause the bundles to break open upon landing. Soil that is muddy or swampy may cause the dropped loads to bury themselves upon landing, making recovery difficult or impossible.

(4) *Topography.* A clear and level area is desirable. Drop zones on a steep slope or mountainside cause the bundles to scatter, tumble, and break open. A mountain or hill top usually has turbulent winds that reduce drop accuracy and make the drift of bundles unpredictable.

(5) *Access.* A desirable drop zone has an adjacent road, or terrain adjoining the area, that offers good access for vehicles, so that the dropped supplies can be recovered and transported conveniently.

Section III. WATER SUPPLY

142. Importance

An adequate supply of water for drinking, sanitation, construction, and vehicle operation is one of the fundamental needs. In arid and semiarid regions, water supply affects plans and operations. Entire campaigns in desert lands may be conducted solely to secure water sources or to deny them to an enemy. All feasible sources and methods for developing them must be considered when making plans for the water supply of troops and installations. Development data are obtained from reconnaissance, map study, reports or runoff and rainfall average, and geological surveys. Water

sources are located by a study of maps, aerial photographs, water resources data, and intelligence reports, then verified by field reconnaissance if feasible. Detailed information concerning water supply is contained in TM 5–700.

143. Sources

a. Basic Considerations. Water may be obtained from wells, streams, springs, lakes, and municipal or other supplies that are already developed. Water for permanent and semipermanent installations also may be secured from the distillation of sea water or the drainage from building roofs. Investigations to select a water source must consider the quantity and quality of the water, and the conditions at the proposed sites from which the water supply would be secured.

b. Quantity. The quantity of water available in an area depends chiefly upon the climate. In temperate and tropical regions with less than 60 centimeters (25 inches) of annual precipitation, most streams become dry in drought periods. Streams usually flow throughout the year in temperate regions with more than 60 centimeters (25 inches) of annual rainfall and in tropical regions where the rainfall exceeds 90 to 100 centimeters (35 to 40 inches). Seasonal variations may reduce the flow of water below the required amount or result in water points being flooded by seasonal high water periods. The seasonal characteristics of water sources should be obtained from local inhabitants. Terrain studies usually indicate alternate water sources for use in case the primary sources dry up, become flooded, or cannot be used because of enemy action.

c. Quality. Color, turbidity, odor, taste, mineral content, and contamination determine the quality of water. TM 5–700 gives methods for estimating these characteristics and describes the use of standard test kits. The quality of water will vary according to the source and the season, the kind and amount of bacteria present, and the presence of dissolved matter or sediment. Streams in inhabited regions commonly are polluted, with the sediment greatest during flood stages. Streams fed by lakes and springs, with a uniform flow, are usually clear and vary less in the quality of water than do those fed mainly by surface runoff. Water in large lakes generally is of excellent quality, the purity increasing with the distance from shore. Very shallow lakes and small ponds are usually polluted.

d. Site Requirements. The ease with which a water source can be developed, operated, and maintained is determined largely by the location and the routes of communication. The design of the collecting system and the difficulties of development, operations, and maintenance are partially influenced by site conditions, topography, soils and vegetation. A military water point should be located as close as possible to a main route without interfering with traffic. An all-weather access road should lead to the place of storage, with a turnaround or separate exit, and an all-weather off-road parking area for trucks waiting to be filled. In locating the water point, attention is given to concealment and cover, possible nearby targets which may attract enemy fire, drainage, road connections, condition of the banks and the bed if surface water is being drawn, and the means required to develop the source. Existing water supply systems are used when carefully checked by engineers and medical authorities. Purification units may have to be installed. The possibility of contamination by enemy agents also must be considered.

144. Surface Water

a. Regional Variations. Surface water sources are generally more accessible and adequate in plains and plateaus than in mountains. Large amounts of good quality water normally can be obtained in coastal, valley, or alluvial and glacial plains. Although large quantities also can be secured in delta plains, the water may be brackish or salty. Supplies of water are scarce and difficult to obtain on lacustrine, loess, volcanic, and karst plains. In the plains of arid regions, water usually cannot be obtained in the quantities required by a modern army. Much of the water that is available is highly mineralized. In the plains and plateaus of humid tropical regions, surface water is abundant, but it is generally polluted by bacteria and requires treatment. Perennial surface water supplies are difficult to obtain in Arctic regions. In summer, water is abundant but often polluted. In winter it can be obtained

from beneath the ice in the larger lakes and streams, but its quality is poor because of a high organic content.

b. Springs and Seeps. There are two types of springs or seeps: those originating at the base of steep slopes where the topography breaks abruptly, and those caused by faulting. The first type is found along the edges of a valley, and has a perennial flow and fresh, cold water. The second type is caused by the fracture or displacement of confining clay or rock layers above an artesian water-bearing formation (aquifer), thus forcing the water in the artesian zone to the surface. Springs of this type often are thermal, and may contain excessive amounts of minerals. Frequently the depth of a source of water can be estimated by the temperature of the water; the hotter the water, the deeper the source. Spring water is generally clear, cool, and low in organic impurities, but may be hard because of a high dissolved mineral content. In regions where seasonal rainfall varies greatly, the spring flow often decreases during long periods of dry weather. The heavy infiltration of surface water causes some springs to become turbid, and may produce contamination.

c. Streams. Streams are the most common source of surface water supply. Streamflow may vary with precipitation, temperature, and the amount of vegetation. Turbidity and mineral content vary with the flow and with watershed conditions. Since large flows produce high dilution, many such streams may be suitable sources of water supply although they receive raw or partially treated sewage. However, water from such streams must be settled, filtered, and chlorinated before use.

d. Lakes. Ordinarily, lakes are a satisfactory source of water supply. The water level and average yield in small lakes may vary. Many lakes receive sewage flow, have a high content of dissolved minerals, and may have considerable vegetative growth or contain vegetable or animal organisms. These can usually be removed by purification processes.

145. Ground Water

a. Source. Ground water is obtained without difficulty from unconsolidated or poorly consolidated materials in alluvial valleys and plains, streams and coastal terraces, alluvial fans, glacial outwash plains, and alluvial basins in mountainous regions. Areas of sedimentary and permeable igneous rocks also may have fair to excellent aquifers, although they do not usually provide as much ground water as areas composed of unconsolidated materials. Aquifers of this type underlie coastal plains, inland sedimentary plains and basins, karst and volcanic plains and plateaus. Large amounts of good-quality ground water may be obtained at shallow depths from the alluvial plains of valleys and coasts, and in somewhat greater depths in their terraces. Large quantities may also be secured from shallow wells in delta plains, although it is apt to be brackish or salty. Aquifers underlying the surface of inland sedimentary plains and basins also provide adequate amounts of water. Often these formations lie with a few hundred feet of the surface. Those at greater depths yield very hard water which may be too highly mineralized to be drinkable. Abundant quantities of good-quality water generally can be obtained from shallow to deep wells in glacial plains. In loess plains and plateaus, small amounts of water may be secured from shallow wells, but these supplies are apt to fluctuate seasonally. Water from wells usually is clear and low in organic impurity, but it may be high in dissolved mineral content.

b. Plains. Large springs are the best sources of water in karst plains and plateaus. Wells may produce large amounts if they tap underground streams. To estimate the possible yield of proposed wells, information is sought about existing wells that tap similar water-bearing formations in the vicinity. The siting and drilling of wells is difficult because the areas of permeability and the solution cavities in limestone cannot be easily predicted. Shallow wells in low-lying lava plains normally produce large quantities of ground water. In lava uplands, where water is more difficult to find and wells are harder to develop, careful prospecting is necessary to obtain adequate supplies. In wells near the seacoast, excessive withdrawal of fresh water may lower the water table, allowing infiltration of salt water which ruins the well and the surrounding aquifer. Springs and wells near the base of volcanic cones may yield fair quantities of water, but elsewhere in volcanic cones the ground water is too far below

the surface for drilling to be practicable.

c. Climate. Plains and plateaus in arid climates generally yield small, highly mineralized quantities of ground water. In semiarid climates, following a severe drought, there frequently is a flow of subsurface water under an apparently dry streambed that may yield considerable amounts of excellent water. Ground water is abundant in the plains of humid tropical regions, but usually it is polluted by bacteria. In arctic and subarctic plains, wells and springs fed by ground water above the permafrost are dependable only in summer; some of the sources freeze in winter, and subterranean channels and outlets may shift in location during the seasons. Wells that penetrate aquifers within or below the permafrost, however, are good sources of perennial supply.

d. Hills. Adequate supplies of ground water are hard to obtain in hills and mountains composed of gneiss, granite, and granitelike rocks. They may contain springs and shallow wells that will yield water in small amounts.

e. Military Use. Both large- and small-diameter wells are used for military installations. Large-diameter wells usually are dug by hand, in diameters up to 15 meters (50 feet). They may be used as reservoirs, the water level falling during periods of withdrawal and being replenished from subterranean flow during periods of light demand. Small-diameter wells, normally, made by driving, jetting, boring, or drilling, do not provide storage. Deep wells are drilled by percussion rigs or rotary equipment. The amount of water obtained from deep wells will depend upon local conditions. They are less subject than shallow wells to seasonal fluctuation, contamination, and pollution. Information about wells and well-drilling is in TM 5–297.

146. Water Supply Systems

a. Types. There are 3 basic types of water supply and distribution systems—

(1) *Gravity.* The storage reservoirs of gravity distribution systems usually are located high enough to develop the required pressure and flow. Sometimes the storage tanks are filled by gravity from springs located at a higher level, but ordinarily they are filled by pumps.

(2) *Direct pumping.* In direct pumping systems, ordinarily there are no elevated storage tanks. The water is pumped into the distribution system from ground storage reservoirs or wells at a rate depending on demand.

(3) *Combination.* Primary mains are supplied by both gravity and direct pumping in combination systems.

b. Parts. The essential parts of a water supply system are—

(1) *Headworks,* usually a reservoir formed by a dam.

(2) *Conduit,* sometimes an open canal or an aqueduct, but more commonly made of wood, iron, or steel that is watertight to prevent contamination and losses by evaporation, absorption, and changes in temperature.

(3) *Distributing* system, which connects with the plumbing in buildings. Large mains carry the water from the source to service pipes, which take it to individual buildings and other outlets.

147. Information Requirements — Water Supply

Special water supply studies are made by engineers, assisted by geologists and hydrologists. The information required in terrain intelligence studies includes the following—

a. General.

(1) Normal level of water table and variations.

(2) Yield of springs and wells, and variations.

(3) Potability and contaminations.

(4) Underground flow in dry watercourses.

b. Surface Supplies.

(1) Total drainage area.

(2) Rainfall and runoff data.

(3) Sources and kinds of possible contamination, including sewage or industrial wastes.

(4) Chemical and bacteriological analyses.

c. Wells.

(1) Rainfall data.

(2) Reports of available well logs and test data.

(3) Physical, chemical, and bacteriological analyses.

d. Existing Water Supply System.

(1) Source of supply.
(2) Quantity provided; ultimate capacity.
(3) Treatment methods.
(4) Distance from supply to proposed military user point.
(5) Pressures.
(6) Chemical and bacteriological analyses.

CHAPTER 8

TERRAIN STUDIES

Section I. BASIC FEATURES

148. Description

a. Preparation. A terrain study is an intelligence product which presents an analysis and interpretation of the natural and manmade characteristics of an area and their effects on military operations. It is a compilation of only that information which has a direct bearing on some existing requirement. This study is prepared at all echelons to provide the intelligence officer with an analysis of the terrain for use in preparing the analysis of area of operations that forms part of his overall intelligence estimate for the commander, and for use by other staff elements for planning and conduct of operations. The preparation of an analysis of area of operations is discussed in FM 30–5. Above army level, terrain studies are prepared primarily, to assist the commander and his staff. At lower levels, terrain studies are intended chiefly for use in tactical operations and include more details of the terrain and its effects.

b. Topics. Special studies devoted exclusively to certain terrain features or effects may be prepared to meet the requirements of a particular plan or operation. These are produced by technical personnel or teams, and include, but are not limited to, studies concerning—

(1) Construction problems.
(2) Movement.
(3) State of ground.
(4) Water resources.
(5) Lines of communication.
(6) Site selection.
(7) Coast and landing beaches.
(8) Inundation.
(9) Urban areas.
(10) Barriers.
(11) Defenses.
(12) Airborne landing areas.
(13) Soils.
(14) Rock types.
(15) Drainage.
(16) Climate.
(17) Surface configuration.
(18) Inland waterways.
(19) Other military aspects.

149. Prerequisite Information

Before initiating the study, one must know the area to be covered, the mission and type of operation, the specific information required, and the time period to be considered. Terrain intelligence is produced continuously at all echelons. The preparing unit maintains a file of intelligence data, drawing upon it for pertinent matter when he is directed to make a terrain study. Additional information is obtained from the sources and agencies discussed in chapter 3.

150. Format

a. Content. A specific terrain study will not cover every item in outline, but only those items applicable to the operation being planned. Used in this manner, the terrain study form insures uniformity of presentation yet permits the flexibility imposed by terrain analysis.

b. Primary Requirement. The primary requirement for a terrain study at army, corps, or division level is that it must present the intelligence in a form that can be easily utilized by field units. The study must be concise, presenting only pertinent information. Written description should be kept to a minimum. Intelligence should be presented graphically whenever possible.

c. Automation. The intelligence portion of

the Tactical Operations System (TOS) automatic data systems within the Army in the field (ADSAF–75) is an information processing system which uses automatic data processing equipment as a tool for battlefield commanders to help them exercise command and control of their forces and make effective and timely decisions. The computer center accepts information from various sources, including that from forward observers as well as from other computer centers. This information is automatically assembled, sorted, evaluated, and stored by the computer. This computer drives an automatic, constantly up-dated map display which provides the commander with a view of his entire operation. The map includes symbols representing the size, type, and location of all forces, both friendly and enemy, as well as the terrain features, supply dumps, and other intelligence information necessary for the effective evaluation and direction of the operation. This computer center consists of a central processor, memory units, and auxiliary equipment. It also has an automatic communications switching capability which permits contact with all units having an organic intelligence section and a primary intelligence collection mission. In addition, it has operating and monitoring controls for the system.

151. Compilation

a. Format. The format suggested for the terrain study consists of three parts: text, a terrain study map, and a regional description section. A fourth major paragraph, "Analysis of Area of Operations," is prepared by the intelligence officer. The scope of this paragraph is described in FM 30–5. The text follows the sequence of the sample terrain study (app. C). It presents the terrain intelligence called for in the applicable section of the form Tables and charts are used to simplify, amplify, and clarify the presentation. The text should be as concise as possible.

b. Map. Wherever possible, terrain intelligence should be presented on a terrain study map, based on a topographic map of appropriate scale. A map scale of 1:50,000 is usually utilized for brigades and divisions. Corps and army headquarters usually do not require a scale larger than 1:250,000. The terrain intelligence is overprinted on the topographic map (printed in gray monochrome) or is an overlay to the map. Appropriate symbols are used to present items of terrain intelligence. Conditions for movement are portrayed by designated movement colors.

c. Regions. Terrain features exist in certain patterns or combinations, which create distinctive terrain regions. Usually the area of study encompasses several terrain regions. The regional description section of the terrain study gives the user an understanding of the terrain by explaining the combined effect of the terrain features in the regions. This section consists of a sketch map delineating the terrain regions and of brief descriptions summarizing the terrain intelligence for each region. It may be printed on the back of the terrain study map. The information presented in the regional description section enables the user to evaluate the factors influencing movement and to interpret changes in movement which might be caused by changes in weather.

152. Reproduction

Reproduction of terrain studies should be done by the fastest, cheapest, and easiest method. Only as many as necessary for primary users should be made. The engineer topographic battalion assigned to army has the capabilities for map reproduction. The battalion can draft and reproduce in bulk the terrain study map mentioned in paragraph 151. It can also perform the other printing and drafting necessary for the reproduction of terrain studies. The engineer topographic company assigned to corps has basically the same capabilities as the topographic battalion in the type of work it can do, but is limited in volume and equipment. A division has no organic topographic units. Terrain studies are produced by means of duplicators which can produce a map-size paper. The type and quality of terrain studies are limited only by the degree of skill and imagination on the part of the personnel who are responsible for this function.

153. Dissemination

The Engineer or Engineer Terrain Detachment, or G2 Staff Engineer Officer, disseminates the completed terrain study to the G2 and other interested staff elements. The G2 utilizes the terrain study according to the tac-

tical situation and presents the resulting terrain estimate to the commander. If necessary, the terrain study is disseminated to subordinate and adjacent units. The terrain study is also disseminated through engineer channels. Copies are sent to lower echelons to assist them in planning and preparing their own terrain studies. A copy is sent to higher engineer headquarters, and another is sent through enginner channels to the Office of the Chief of Engineers.

Section II. TERRAIN AND CLIMATE

154. Basic Factors Affecting Terrain

The basic factors for a terrain analysis are discussed under item 2 of the terrain study (app C). The factors discussed are climate, topography, and when applicable, coastal hydrography. Although climate and oceanographic aspects of coastal hydrography are not elements of terrain, they have a direct influence on the usefulness of an area for military activities. Appendix C compiles the terrain intelligence that is pertinent to the area of the planned operation. The extent of the area will vary with the echelon performing the compilation. Terrain studies at higher echelons may present fairly extensive descriptions for planning purposes, but terrain studies at lower echelons, having a more definite direction and limit as to area, time, and purpose, restrict their descriptions to the intelligence applicable to the operation planned.

155. Climate

a. Elements. The elements of the climate discussed in a terrain study include visibility, temperature, precipitation, humidity, winds, clouds, and electrical disturbances. Not all must be discussed in every terrain study, because the factors selected depend on the area, time, and type of operation planned. The area of operations influences the description of the climate. The climate of a large area may be described in general terms, whereas a description of a small area will be quite specific. The importance of certain elements of climate depends upon the area. The time that an operation commences determines the type of intelligence presented. Climatic data must be used if the starting date is more than a week or two in the future. (Weather forecasts will be used in the terrain estimate for 5 days or less.) The type of operations planned determines the pertinent elements of climatic information to be furnished. Planning of airborne operations, amphibious operations, and other special operations requires knowledge of weather elements not usually required in normal ground operations. These considerations are discussed in greater detail in manuals pertaining to airborne and amphibious operations.

b. Factors. The methods of describing various factors of climate are discussed below.

(1) *Visibility.* Certain fixed data are best presented graphically. Times of sunrise, sunset, moonrise, moonset, BMNT, EENT, and phases of the moon are best presented on a chart to indicate periods of degree of visibility. Such a chart is included in the sample terrain study. Where pertinent, tide movements can also be presented on this chart. Other deterring influences on visibility, such as fog, smoke, dust, or snowstorms, are discussed in the text.

(2) *Temperature.* This information is generally presented in tabular form. Temperature predictions based solely on climatic studies cannot forecast the expected temperatures, but can describe the range of temperatures that can be expected in a particular location by either of two methods. By the first method, the mean temperature, the mean maximum and mean minimum, and the absolute maximum and absolute minimum temperatures which can be expected for the period can be indicated. The mean temperature alone has little significance since it gives no indication of the range of the temperature variation. The second method is to tabulate the number of days of the period that the temperature can be expected to exceed or

fall below stated temperatures. Temperature effects on other terrain features should be described adequately when significant, such as effect on soil trafficability and freezing or thawing of water bodies.

(3) *Precipitation.* This information, based on climatic studies, can state the type and amount of precipitation encountered during a particular period; the number of days within that period on which certain amounts of precipitation can be expected; and the variability of precipitation from year to year. A statement of the total amount of precipitation that can be expected over a period of time has little significance in itself, since a 3-inch rainfall means one thing when spread over 30 days and a totally different thing when concentrated in 1 day during the 30-day period. The effect of precipitation on other terrain features, particularly water bodies and the trafficability of soils, should be described.

(4) *Winds.* Wind data based on climatic research present the direction, intensities, and duration that can be expected over a period of time. These facts are best expressed graphically by means of a wind rose or may be referenced to the Weather Map Scale of Wind Velocity. Wind rose data may be secured from AWS when specifically required by a commander. The effect of wind on surface materials and on waves is described when pertinent.

(5) *Humidity.* Exact descriptions of humidity are not usually necessary, but the effects of humidity on operations is described when significant. The description should consider fog conditions and the effect of humidity in reducing the efficiency of personnel or in creating problems of storage and maintenance of supplies and equipment.

(6) *Clouds.* Data based on climatic records signify the approximate number of days during a specific period that a certain degree of cloud cover can be expected. There is also a statement as to what time of the day or night certain cloud coverage can be expected. Related conditions such as storms and fog are also described when applicable.

(7) *Electrical disturbances.* This subject is discussed only when it has an important effect on proposed operations. The type of disturbance, its period of occurrence and duration, and its effect on planned operations are described in the text when pertinent.

156. Natural and Manmade Features

a. Relief. Relief is described in the text and symbolized on the map to highlight significant relief features, but not to repeat the detail of a topographic map. The general picture of the relief of an area may be indicated by ridge and stream lining, which accentuates the major ridges and drainage patterns. This consists of emphasizing the streams by drawing over them with a blue pencil and emphasizing ridges with brown pencil. Ridge lining or stream lining can be used separately, if desired, but the combination of the two is more effective. Ridge and stream lining emphasizes the compartmentation of an area, but does not show relative elevations or slope (fig. 57). Another method is to emphasize the principal contours of an area. This is done by tracing over certain critical contour lines with a heavy black pencil or by using different colored pencils to indicate different elevations. This method has the advantage of not obscuring details on the map (fig. 58). Sharp slopes, such as embankments, steep riverbanks, and cliffs are indicated by a red movement symbol when traverse appears to be impracticable. In certain cases, an area may be cut by numerous draws and gullies which are significant but are not shown on topographic maps because their depths are less than the contour interval. These draws and gullies are symbolized on the map. The effect on movement is discussed under "movement" and illustrated graphically by movement symbols.

b. Drainage and Hydrography. Since drain-

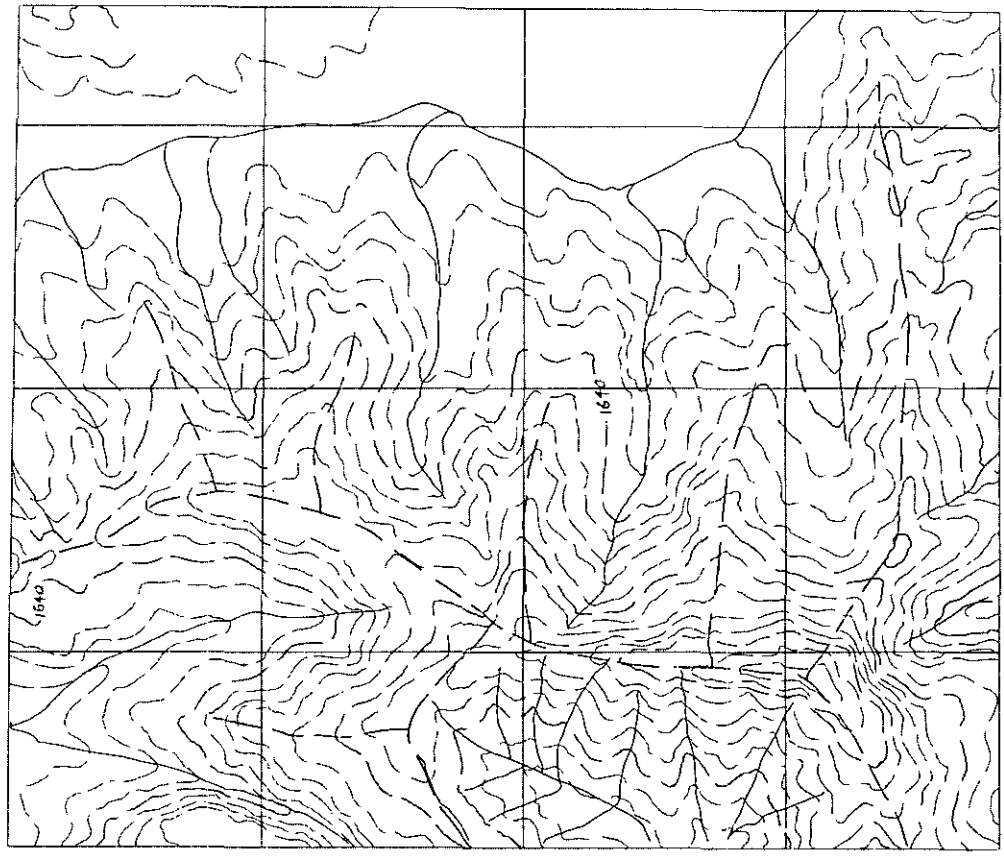

Figure 57. Ridge and stream lining.

age features are subject to change at least seasonally, it is important that the terrain study describe the present condition of the drainage features. The degree of detail in the description is usually determined by the echelon at which the study is prepared and the primary purpose of the study itself. A higher echelon indicates only the major features on the terrain study map, but lower echelon study covering a smaller area can indicate the minor drainage features and give detailed descriptions of them.

c. Vegetation. Forests are indicated graphically. The type of trees, deciduous and evergreen, the density of the forest, and the range of trunk diameters are noted on the map. The text describes other significant vegetation in the area and the effect of weather on the vegetation. Vegetation may be discussed under concealment, fields of fire, obstacles, and any other pertinent aspects of the terrain.

d. Surface Materials. Higher echelon terrain studies usually include a soils map. At army and lower headquarters, this will not usually be feasible. A description of the types of surface materials is included in the surface material section of the study. The effect of surface materials on cross-country movement is an important factor of the terrain study and is described graphically in that section. Surface materials are also discussed in the sections on construction sites and construction materials.

e. Manmade Features. The terrain study describes those manmade terrain features which have particular significance or which require more detailed description to be of value. The more common manmade features are discussed below.

(1) The road-bridge-bypass system is described because of its influence on vehicular movement. A higher echelon study may describe graphically only the primary roads whereas a division study usually describes the secondary

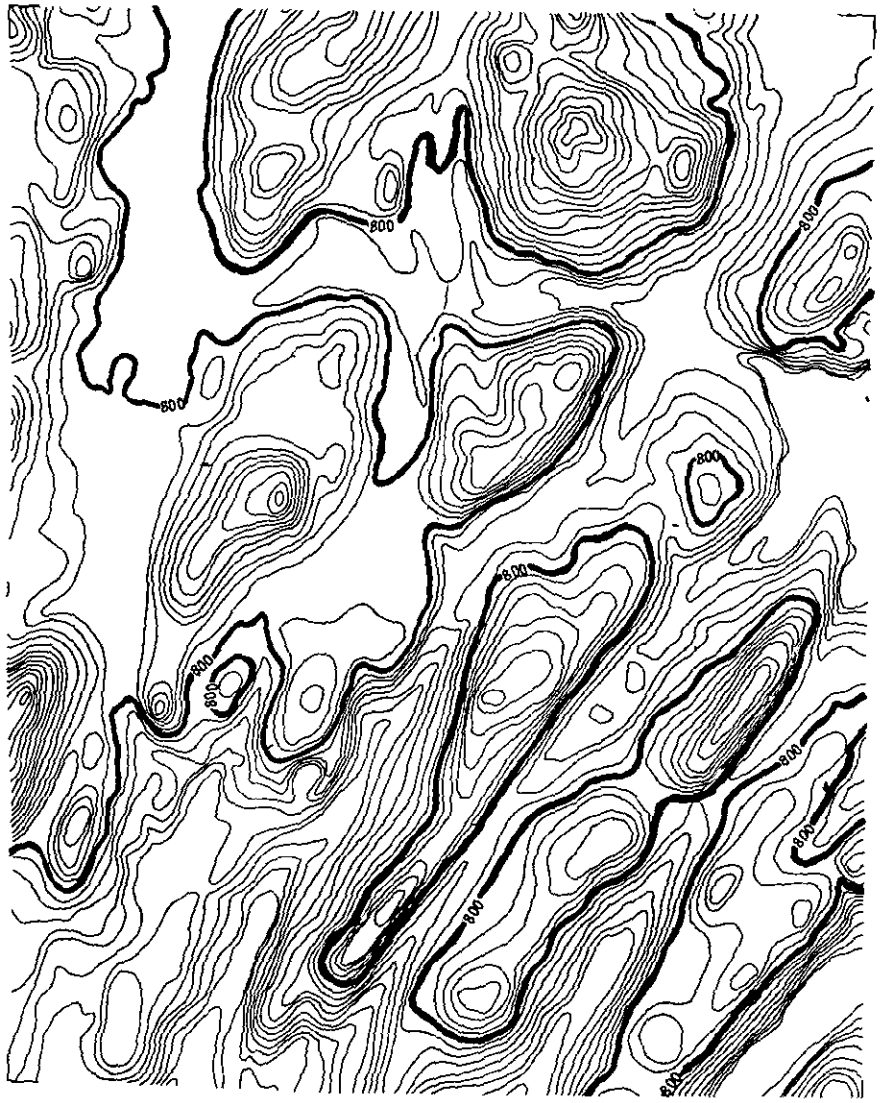

Figure 58. Contour emphasis.

and tertiary systems as well. Important bridges and bypass sites are indicated. (See DIA, AP-1-335-3-1-65 -ADMIN and DIAM 57-5 for route classification symbols.)

(2) Airfields of all types are described. Their locations are shown on the map by standard topographic symbols and an indication is given as to their size and condition. Further details are given in a table.

(3) Principal cities and towns are indicated on the terrain study map, and are listed further in a table.

(4) Railroads are shown on the terrain study map, with detailed information in a table.

(5) Hydrologic structures of all types are described, with detailed information in a table.

Section III. MILITARY ASPECTS

157. Operations

Determining the military aspects of the terrain for an operation requires a knowledge of the terrain and of the operation planned.

Not having complete knowledge of any specific military operation, the person preparing the terrain study should describe the military aspects in terms of generalized operations. The intelligence officer using the study will interpret them in terms of the operation being planned. This is particularly true of key terrain features and avenues of approach. Descriptions of the aspects of terrain vary with the echelon. At army level, descriptions are general; at division level they are more detailed and specific.

158. Key Terrain Features

The determination of key terrain features requires a knowledge of the terrain, the objective, and the plan of operations. As a rule the person making this study may not have a complete knowledge of the plan of operations, and therefore, he must determine those features that have a controlling effect on the surrounding terrain and list them as probable key terrain features for consideration by the user. The description of these features includes a discussion of their significance.

159. Observation and Fields of Fire

a. Observation. The description of observation includes an evaluation of the ground and air observation in the area, and a brief discussion of the terrain features in that area that affect observation. Periods of visibility are described by a visibility chart in the weather and climate section. The effect of the terrain on observation by special devices such as radar, infared equipment, and sound-ranging devices is described when applicable. The description of observation is generally included in the text. A lower echelon study map may indicate the location of individual observation points.

b. Fields of Fire. The description of fields of fire in the terrain study is included in the text, and is primarily concerned with flat-trajectory fire. The description includes a general evaluation and a discussion of the terrain features that affect fields of fire. Features which limit or restrict fields of fire are described in detail. Terrain features that create special problems in the use of high-trajectory weapons are described when they exist. (Areas of marsh or volcanic ash that smother explosive shells are examples of such features.) The possible effect of terrain on nuclear actions is described when pertinent.

160. Cover and Concealment

This includes a discussion of the problem of constructing installations to provide cover, such as foxholes, bunkers, and underground installations. The means available for providing cover from nuclear action is discussed when applicable. Concealment is described in the text with reference to pertinent terrain features such as forests which are portrayed graphically. The amount of concealment and to what extent various type units can utilize it are discussed.

161. Obstacles

The description of obstacles includes a description of the general hindering characteristics of the terrain and a description of specific obstacles. The explanation of the general obstructive elements of the terrain is an overall description and includes terrain features which are unimportant singly, but which constitute obstacles cumulatively, such as systems of irrigation or drainage ditches, terraces, and hedgerows. These are described in the text and indicated graphically by movement symbols. Specific obstacles, such as rivers or escarpments, are described individually. Obstacles that are known to be impracticable for crossing by personnel or equipment are outlined by red hachuring.

162. Avenues of Approach

The determination of avenues of approach involves a summation of all other military aspects as they affect the mission of a particular force. Fixing the avenue of approach involves a tactical decision which is beyond the scope of the engineer intelligence officer. His role in the preparation of a terrain study is to present information on the available avenues of approach for consideration by the G2 and the commander. This information is included in the text. It includes a description of the avenues of approach and a brief discussion of their advantages and disadvantages.

163. Movement

The description of cross-country movement

conditions is the most important and detailed of the descriptions of military aspects of the terrain. The description of movement in the text is devoted to a general evaluation of conditions for movement in the area and a discussion of the terrain features and weather conditions which affect movement. Movement is shown graphically on the terrain study map by color symbols which represent an evaluation of movement conditions. The effect of all terrain features is considered in the text on movement evaluation. The specific meaning of symbols as applied to the area of study is explained in the margin of appropriate classification symbols. A more complete discussion of areas of poor or doubtful movement than is possible on the terrain study map is contained in the regional description section, to enable the commander to determine conditions under which movement is possible through the area.

164. Construction Materials

The description of construction materials presents information on the availability of construction materials in the area of operations. It includes data on the presence of developed and undeveloped sources of rock, sand, gravel, and aggregate, and of stocks of lumber, steel, and other construction materials. It is not a detailed report, but presents general data on the availability of materials for construction in the area. Availability of building materials is discussed generally under military aspects of the terrain. Detailed reports on the sources of construction materials are prepared separately as required by engineer units.

165. Suitability of Sites for Construction

The description of construction sites includes a discussion of sites for roads, airfields, and other surface and underground installations. This description should be suited to the needs of the echelon for which the study is prepared. The description does not indicate specific sites, but describes the general suitability of the area for various types of construction. Building sites are discussed generally in the text. Detailed reports on appropriate sites for specific construction projects are prepared separately as required.

166. Water Supply

The description of water supply enumerates the sources of water available in the area and evaluates their suitability for use by the troops. It includes a discussion of natural water sources and water supply systems. When pertinent, the water requirements of the civilian population are discussed. Water supply is discussed in the text.

Section IV. COASTAL HYDROGRAPHY

167. Describing Coastal Hydrography

a. Presentation. Descriptions of coastal hydrography are of interest primarily for amphibious operations. They differ from overland operations only in the method of transportation and types of routes by which they arrive at the area of operations. The terrain study for an amphibious operation includes: text, terrain study map, and tables. These are the same elements which are in the land-operation study, but the terrain study for an amphibious operation must also include a means for presenting detailed intelligence about the landing area. This is done by extending the three elements of presentation mentioned above to include descriptions of the landing area, and by use of a fourth element, the beach profile diagram. Application of this method of description to coastal hydrography is discussed below.

b. Text. The text describes the features of coastal hydrography, such as sea approaches, beach area, sea and surf, and tides. The description is coordinated with the graphic presentation. The effect of other terrain features on coastal hydrographic conditions is also described, and includes the effect of inland surface materials on beach composition.

c. Terrain Study Map. The terrain study map shows potential amphibious landing areas. Since the terrain study map may be of too small a scale to be of value as a description of the landing area, it is generally used to depict the configuration of the coast line, location and length of the beaches, and location of exits from the beaches.

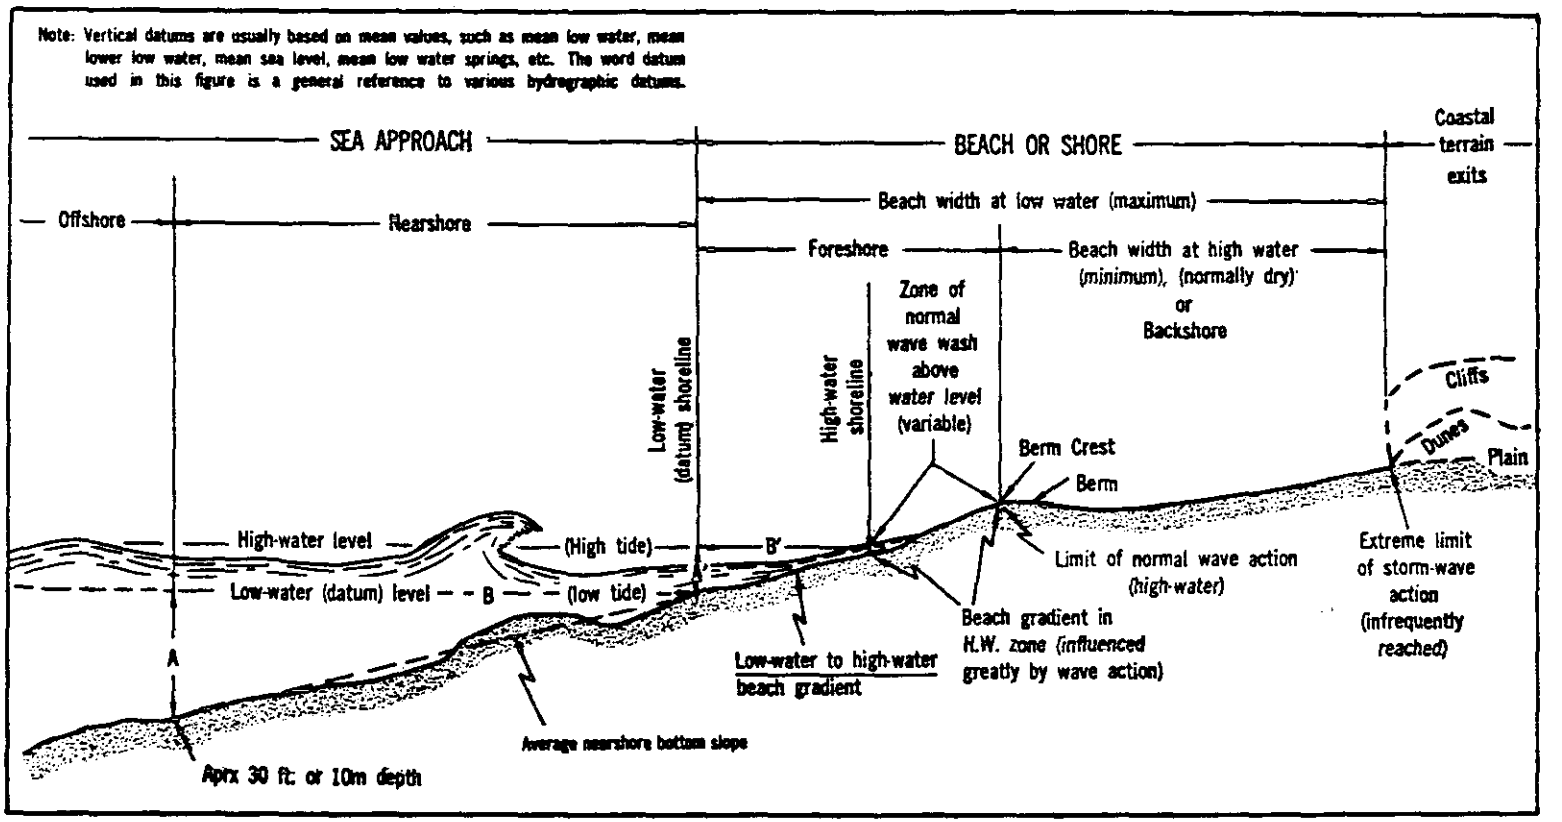

Figure 59. General beach profile diagram (tidal sea).

d. Description. A description of both the hydrographic and terrain conditions for each landing area is included in a table.

e. Beach Profile Diagram. The beach profile diagram (fig. 59) is a large scale sketch of the offshore and nearshore area, the shore, and the coastal terrain (hinterland). The water levels at high tide and low tide are shown in the offshore, nearshore, and foreshore areas. In addition, the beach widths at high water level and low water level and some of the coastal terrain are shown. A profile of the area to the rear of the beach, showing landmarks visible from the sea, is included if deemed necessary as a navigation aid for landing craft. Other data may be included if it is pertinent to the operation.

168. Sea Approaches

a. Offshore Approaches. The offshore approaches are usually of interest only to naval forces and therefore are not described in the terrain study. When description is necessary, a hydrographic chart may be utilized.

b. Nearshore Approaches. The nearshore approaches are of primary interest to landing forces and, as such, require a detailed description. The description should present a general evaluation of the nearshore area, and describe bottom conditions and the effect of sea, swell, breakers, surf, tides and currents. Also described are any special phenomena such as sea vegetation thick enough to be classed as an obstacle, ice conditions, unusual or tricky currents. The landing area map presents a graphic description of the nearshore area. The general relief of the area is described by contours based on the hydrographic chart datum plane. Obstacles are located on the map and any special features are identified by special symbols. Representative profiles, as necessary, describe the gradient of the nearshore area.

c. Beaches and Beach Exits. The text presents a general description of the beach area, covering such items as the capacity of the beach, its composition and trafficability, and the capacity of beach exits. The terrain study map describes the general configuration of the coast, the location and length of the beaches, and the beach exits. The regional description deals with the beaches as part of topographic regions. The landing-area map presents a detailed graphic description of the beaches. It portrays the dimensions of the beaches and the location of obstacles areas, and describes the beach exits. The colors used in the landing-area map conform to the color key used in all movement maps. The water tint usually extends to the high water shoreline, or at time to mean sea level, depending upon the mapping agency. One or more profiles are used to describe the beach gradient. If necessary, the area to the rear of the beach is included to indicate the position of landmarks as seen from seaward.

d. Sea and Swell. Sea is defined as waves caused by local winds, whereas swell refers to wind-generated waves that have advanced beyond the region of generation. The direction of sea is that of the local wind, whereas the direction of swell is independent of, but may coincide with the local wind. Both sea and swell may be present at the same time. Sea and swell must be described in the text, with roses that show the frequency of various height categories by direction.

e. Breakers and Surf. Surf is the disturbed water area extending from the outer breaker line to the limit of uprush on the beach. Breakers are waves that shoal over a reef or on a shore. Hazards to landing increase with increasing breaker height, and vary with period of waves, type of breakers, and the direction of breaker approach onto the beach. Breakers and surf are described by the text, and breaker roses show frequency by direction of specified breaker height ranges.

f. Tides. Tide information is presented graphically. Curves portray times of high and low tides, and can be incorporated into the visibility chart. A chart showing the tides during the period of the study is included in the margin of the landing-area map for predicting the heights of the water at any given time. Special tidal conditions and tidal currents are described in the study text.

CHAPTER 9

TRAFFICABILITY

169. Estimating Soils Trafficability

The purpose of this chapter is to assist intelligence and reconnaissance personnel to determine the trafficability of soils to support cross-country movement of military vehicles. Increased emphasis on the military concept of dispersion, which requires cross-country movement has increased the requirement for information on soil trafficability. Most information on trafficability pertains to military vehicles operating on various unfrozen soils in the temperate zones. The procedures for measurement of soil trafficability can also be applied to unfrozen soils that have been subjected to freeze-thaw cycles. An estimate of trafficability can be made with the aid of this chapter if something is known of the general weather conditions, the topography and the soils of the area.

170. Weather and Climate

Information about the weather and climate is available from meteorological records, and climatology textbooks, and by interrogation of prisoners. Only two general conditions of weather apply to trafficability estimates, the dry period and the wet period.

a. Trafficability During Dry Period. During a dry period all soils usually are passable unless the area is low-lying and poorly drained or is kept wet by underground springs. Sand in a dry state is less trafficable than in a wetter condition (with the exception of quicksand).

b. Trafficability During Wet Period. When moisture is added to a soil its strength is changed. Different soils are affected differently by moisture. During a wet period, all soils with the exception of clean sands and gravels provide poor trafficability. The relative trafficability ratings of soil types under set conditions are given in figure 60. This figure is explained in paragraph 178.

171. Topography

The effects of slopes on soil requirements for vehicle performance can be shown in quantitative units when actual measurements of the cone index (para 174*d*) can be made, but in estimates of trafficability only general statements concerning slopes are feasible. Slopes require better soil traction conditions for vehicle movement than does level terrain of a similar soil type. Other factors pertaining to trafficability that must be kept in mind are that ridges are generally more trafficable than the adjacent valley, that downhill travel is easier than uphill travel, and that low tire pressure increases traction. During the dry season, sand slopes of approximately 30 percent are impassable. Fine-grained soils and sands with fines which are poorly drained may be trafficable up to a 45 percent slope. During the wet season a 30 percent slope is the maximum that should be tried on any type soil.

172. Soils Maps

Two types of soils maps exist. One type classifies the soils according to the Unified Soil Classification System (USCS), as used in determining trafficability. The second type of soils map employs the agricultural system of soil classification (ASSC). This type is not used by the military. It is mentioned here to avoid confusing it with the USCS. Soils are formed by the action of the following factors: parent material, climate, age, chemical action, topography, and vegetation. A trained analyst can estimate the soil types by using a geologic map, providing he has a general knowledge of the climate, the topography, and the vegetation of the area.

173. Aerial Photographs

The full utilization of aerial photos in estimating trafficability is presently being studied. At present the following information pertaining to trafficability is obtained from aerial photographs.

a. Topography. Aerial photographs are a good source of topographic information. Estimates of elevations and slopes can be made from stereopairs by properly instructed personnel. Accurate elevations and slopes can be obtained by trained operators using mechanical equipment such as Multiplex and Kelch plotters.

b. Soils and Moisture Conditions. In the present stage of development, the techniques for identifying soils from airphotos are so complex that only well-trained technicians can employ them to their fullest extent. However, certain general facts may be used to advantage by personnel with a minimum of training. For instance, orchards usually are planted in well-drained, sandy soils; vertical cuts are an evidence of deep loessial (silty) soils; tile drains in agricultural areas indicate the presence of poorly drained soils, probably silts and clays. On a given photo, light color tones generally signify higher elevations, sandier soils, and lower moisture contents than do dark color tones. The same color tone does not always indicate the same soil conditions even on the same photo. Color tone may have entirely different significance on two separate photos. Also, natural tones are apt to be obscured and modified by tones created by vegetation (natural and cultivated), plowed fields, and shadows of clouds.

c. Vegetation. Dense grass, especially if wet, will cause slipperiness. Tall grass will often restrict visibility. Heavier vegetation such as brush and trees will decrease trafficability if the vehicles must push aside this vegetation as they advance. The presence of vegetation in sands usually stabilizes the soil, thus increasing its trafficability. Decaying vegetation including the roots, found especially in the northern latitudes, adds to the support of the soil if the soil is weak. The limited testing that has been done shows that if the mat of partially decayed vegetation is 6 or more inches thick it will support 40 to 50 passes of very light vehicles such as the M29 amphibious cargo carrier. Heavier vehicles will break through after 2 or 3 passes.

d. Obstacles. A complete assessment of the trafficability of a given area must include an evaluation of obstacles such as forests, rivers, boulders, ditches, hedgerows, steep slopes and cliffs, and embankments. Aerial photographs are valuable in identifying these features.

174. Trafficability Terms

a. Trafficability. The capacity of a soil to withstand traffic of military vehicles.

b. Bearing Capacity. The ability of a soil to support a vehicle without excessive settlement of the vehicle. California Bearing Ratio is used in denoting design values.

c. Traction Capacity. Ability of a soil to resist the vehicle tread thrust required for steering and propulsion.

d. Cone Index. A numerical indication of the carrying ability (resistance to penetration by wheels and tracks of vehicles) of a soil. An index of the shearing resistance of soil obtained with the cone penetrometer; a dimensionless number representing resistance to penetration into the soil of a 30° cone with a ½-sq in. base area (actually load in pounds on cone base area in square inches). TM 5–530 discusses this in detail.

e. Remolding. The changing or working of a soil by traffic, or by a remolding test. Remolding may have a beneficial, neutral, or detrimental effect on soil strength.

f. Remolding Index. The ratio of remolded soil strength to original strength, determined in accordance with procedures described in TM 5–530.

g. Rating Cone Index. The measured cone index multiplied by the remolding index; it expresses the soil-strength rating of an area.

h. Critical Layer. The soil layer in which the rating cone index is considered a significant measure of trafficability, or the layer of soil which is regarded as being most pertinent to establishing relationship between soil strength and vehicle performance. Its depth varies with the weight and type of vehicle and the soil

profile, but it is normally the layer lying 6 or 12 inches below the surface.

i. Vehicle Cone Index. The index assigned to a given vehicle that indicates the minimum soil strength in terms of rating cone index required to permit 50 passes of the vehicle.

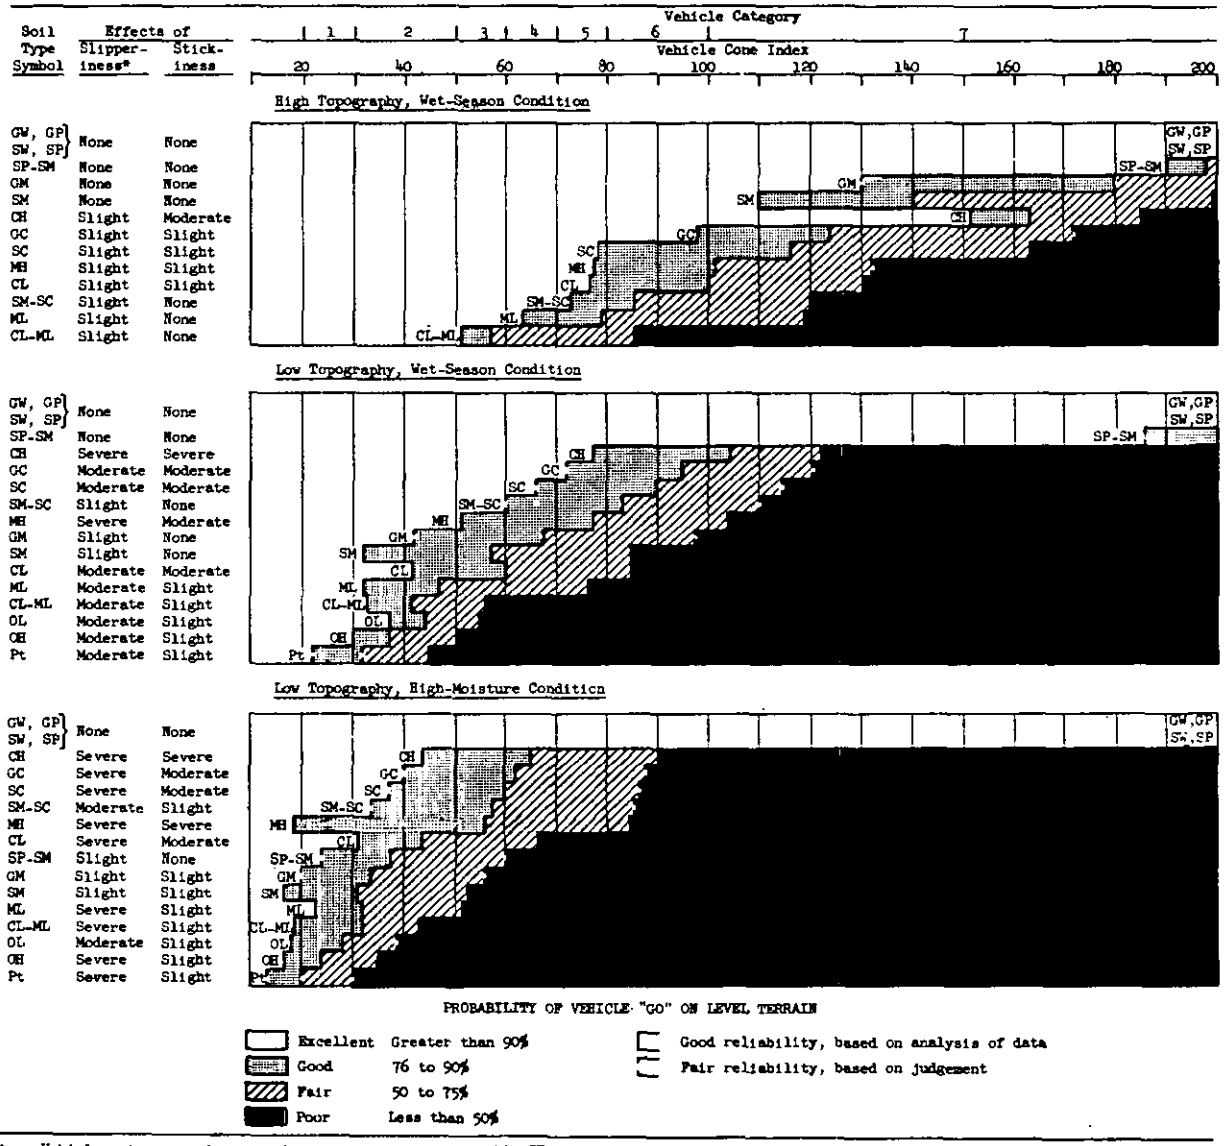
j. Stickiness. The ability of a soil to adhere to vehicles, wheels, and tracks.

k. Slipperiness. Low traction capacity of a soil's surface due to its lubrication by water or mud.

l. Mobility Index. A dimensionless number which results from a consideration of certain vehicle characteristics.

m. Maximum Tractive Effort. The maximum continuous towing force or pull a vehicle can exert expressed as a ratio or percentage of its own weight.

n. Fine-Grained Soil. A soil of which more than 50 percent of the grains, by weight, will pass a No. 200 sieve (Unified Soils Classification System (USCS)).



Note: Vehicle category and cone index range are given on table II.

* Applies only to wheeled vehicles without traction devices.

Figure 60. Soil trafficability classification (USCS).

o. Coarse-Grained Soil. A soil of which 50 percent or more of the grains, by weight, will be retained on a No. 200 sieve.

p. Sand with Fines, Poorly Drained. A sand in which water content greatly influences the trafficability characteristics. These soils react to traffic in a manner similar to fine-grained soils. They usually contain 7 percent or more of material passing the No. 200 sieve, and little or no gravel.

175. Soil Trafficability Table

a. Soil Type Symbols. The soil type symbols used on figure 60 are those employed in the Unified Soil Classification System (USCS). The symbols are given on the extreme left of the figure and also in the graphic portion. The duplication aids in the reading of the graphs. These letter symbols are explained in table 2. Hyphenated letters indicate a mixture of types of soils.

Table 2. Soils Symbols

Symbols	
GW	gravel-sand mixtures, little or no fines.
GP	gravel-sand mixtures, little or no fines.
SW	gravelly sands, little or no fines.
SP	gravelly sands, little or no fines.
CH	inorganic clays of high plasticity, fat clays.
GC	gravel-sand-clay mixtures.
SC	sand-clay mixtures.
CL	gravelly clays, sandy clays, inorganic clays of low to medium plasticity, lean clays, and silty clays.
GM	gravel-sand-silt mixtures.
SM	sand-silt mixtures.
ML	low plasticity silts.
MH	inorganic silts, micaceous or diatomaceous fine sandy or silty soils and elastic silts.
OL	organic silts and organic silty clays of low plasticity.
OH	organic clays of medium to high plasticity and organic silts.

Peat, muck, and swamp soils are not classified in the above list because such soils are almost always impassible except for light amphibious-type vehicles.

b. Strength Measurements. The probable ranges of the cone index (CI), the remolding index (RI), the rating cone index (RCI), and the mean rating cone index are given on figure 60 for those desiring this technical information. For most trafficability purposes this information may be folded out of view to simplify the reading of the remainder of the trafficability chart. Information on the strength measurements is given in TM 5–530.

176. Slipperiness and Stickiness

The information on figure 60 pertaining to stickiness and slipperiness is self-explanatory. The following is general information on each of these two factors.

a. Stickiness. No instrument for measuring the effects of stickiness on the performance of vehicles has been devised. Stickiness will occur in all fine-grained soils when they are comparatively wet. The greater the plasticity of soil, the more severe are the effects of stickiness. In general, stickiness will have adverse effect on the speed and facility of travel and steering of all vehicles. It will immobilize small tracked vehicles like the M29 weasel, but will not stop the larger and more powerful military vehicles. Removal of fenders will reduce stickiness effects on some vehicles.

b. Slipperiness. Like stickiness, the effects of slipperiness cannot be measured quantitatively. Soils which are covered with water or a layer of soft plastic soil usually are slippery and often cause steering difficulty, especially to rubber-tired vehicles. They can often immobilize vehicles, especially when slipperiness is associated with low bearing capacity. Slipperiness effects assume greater significance on slopes. Sometimes slopes whose soil strength is adequate may not be passable because of slipperiness. The use of chains on rubber-tired vehicles usually will be of benefit in slippery conditions.

177. Vehicle Categories

Military vehicles are divided into seven categories according to a cone index range as shown in table 3. These vehicle categories, 1 through 7, are shown at the top of figure 60.

a. Vehicle Cone Index. This index is shown directly below the vehicle category range on figure 60. It is helpful in showing the trafficability of vehicles below category 1 and subdivides each of the seven vehicle categories, especially category 7.

Table 3. Vehicle Categories

Category	Vehicle cone index range	Vehicles
1	20–29	The M29 weasel, M76 Otter, and Canadian snowmobile are the only known standard vehicles in this category.
2	30–49	Engineer and high-speed tractors with comparatively wide tracks and low contact pressures.
3	50–59	The tractors with average contact pressures, the tanks with comparatively low contact pressures and some trailed vehicles with very low contact pressures.
4	60–69	Most medium tanks, tractors with high contact pressures, and all wheel-drive trucks and trailed vehicles with low contact pressures.
5	70–79	Most all-wheel-drive trucks, a great number of trailed vehicles, and heavy tanks.
6	80–99	A great number of all-wheel-drive and rear-wheel-drive trucks, and trailed vehicles intended primarily for highway use.
7	100 or greater	Rear-wheel-drive vehicles and others that generally are not expected to operate off roads, especially in wet soils.

b. Graphic Portion of Figure 60. The legend for the shading of the three graphic portions of figure 60 is given at the bottom part of the figure. The white indicates excellent trafficability, the stippled good, the striped fair, and the black indicates poor to intrafficable soil. The topography and soil conditions are shown in the following three graphs in figure 60.

(1) High topography, (higher areas of the terrain) wet-season condition.
(2) Low topography, (low areas of the terrain) wet-season condition (saturated).
(3) Low topography, high-moisture condition (wet, but below saturation point).

178. Use of Figure 60

a. Mission. You have a rear-wheel drive truck with which to deliver supplies cross country to another area. You have the following information:

(1) Vehicle cone index: 85
(2) Topography: level high topography
(3) Type of soil: clayey sands (SC)

b. Question. Is this trip feasible from the standpoint of trafficability?

c. Procedure in Determining Trafficability.

(1) You know that the vehicle cone index of the truck is 85. Table 3 shows the vehicle to be in category 6. The vehicle cone index range (80–99) to the right of the category in table 3 and the written description under *vehicles* verify the category of your truck.
(2) Locate vehicle category 6 at the top of figure 60.
(3) Find the vehicle cone index 85. The number 85 must be interpolated on the vehicle cone index line in the space between 80 to 100.
(4) Find the soil type SC. This is given under *Soil type symbol* in the left column of the figure, and more conveniently on the graphic portion of the figure.
(5) From the 85 (interpolated) on the vehicle cone index, move downward on the high topography, wet-season condition graphic rectangle to the area marked SC. This area is stippled. Your legend at the bottom of figure shows that the trafficability for your vehicle is *good* in this area. Therefore, the trip is feasible from the standpoint of trafficability. The marking around the soil type area on the figure indicates that the trafficability interpretation on the chart has good reliability, as you may note in the legend. (Good reliability, based on analysis of data.)

d. Trafficability for Same Truck and Soil Type on Low Topography, Wet-Season Condition. From the 85 (interpolated) on the vehicle cone index, move downward into the *low topography, wet-season condition* graphic rectangle to soil type SC. Note that the trafficability is *good*, as indicated by the stippling. Reliability of this trafficability interpretation is fair, based on judgment.

e. Trafficability for the Same Truck and

Same Soil Type on Low Topography, High Moisture Condition. From the 85 (interpolated) on the vehicle cone index, move downward into the *low topography, high-moisture condition* graphic rectangle to soil type SC. Note that the trafficability is only *fair*. Had the vehicle cone index been a few points higher, the trafficability would have been *poor*. The black on this graphic chart indicates poor trafficability and is a warning to "stay off."

APPENDIX B

OUTLINE FOR TERRAIN STUDIES

1. Purpose and Limiting Considerations

State the purpose and limiting considerations under which the study is being prepared. This statement should include the scope of the study in area, time, and subject matter, and any information on the tactical situation, mission, or method of operations that is pertinent to the study.

2. General Description of the Terrain

a. Synopsis. State briefly the impact of the terrain on military operations.

b. Climatic Conditions. Describe predicted meteorological conditions for the period, based on climatic data. Present climatic data graphically whenever possible. The requirements of the study will determine the exact information presented and the manner of presentation.

(1) *Temperature.* Climatic data—give frequency of occurrence of temperatures during period.

(2) *Precipitation.* Climatic data—state frequency of occurrence of precipitation by type and amount.

(3) *Winds.* Climatic data—give frequency of occurrence of winds of certain velocities and direction. Use wind rose.

(4) *Visibility.* Present graphically data on times of sunrise, sunset, twilight, moonrise, and moonset. Describe effect of fogs, mist, haze, and other influences on visibility. State expected visibility by distance when applicable.

(5) *Cloudiness.* Describe when applicable and separate from precipitation and visibility. Climatic data—give data of frequency of occurrence and time of occurrence of various cloud conditions.

(6) *Humidity.* Describe only when significant. Describe effect when combined with other weather elements, such as oppressive heat or wind chill.

(7) *Electrical disturbances.* Describe only when significant.

c. Topography. If pertinent, describe the following characteristics by written or graphic means. Recommend the use of a topographic map overprint to emphasize particular characteristics.

(1) *Relief and drainage systems.* Use ridge and stream lining, contour emphasis, hilltopping, or relief shading to outline the ridge and valley systems. Use numbers, words, or standard symbols to indicate critical relief or drainage conditions.

(2) *Vegetation.* Indicate location, type, and size of trees, density of planting, existence of undergrowth, and the location, type, and density of other significant vegetation.

(3) *Surface materials.* Indicate the type and distribution of soils, subsoils, and bare rock in the area. Indicate their trafficability under various weather conditions.

(4) *Manmade features.* Describe fully the significant manmade features. Include roads, railroads, bridges, tunnels, towns, important buildings, fortifications, or airfields when pertinent.

(5) *Special features.* Describe significant special features such as earthquake zones or active volcanoes.

d. Coastal Hydrography. Describe when applicable. Use graphic means whenever possible.

(1) *Sea approaches.* Describe nature of approaches, bottom conditions, ob-

stacles, gradients, and coastal structures. Use landing-area map to present information graphically.

(2) *Beaches.* Describe dimensions, trafficability, and beach exits. Use land-area map to present information graphically.

(3) *Tides and currents.* Describe expected time of occurrence and stage of tides. Present graphically. Describe currents by direction, velocity and duration.

(4) *Sea and surf.* Describe height of sea. Describe type of surf, width of surf band, height of surf, and expected duration.

3. Military Aspects of the Terrain

From an analysis of the factors of climate, topography, and coastal hydrography, determine the following military aspects and describe them by written or graphic means. Use of an overlay to the basic topographic map is recommended.

a. Tactical Aspects of the Terrain. The following aspects are those basic to all tactical operations.

(1) *Observation.* Determine the effect of the terrain factors on observation from the ground, from the air, and by means of electric or sonic devices when applicable.

(2) *Fields of fire.* Determine the effect of the terrain factors on the ability of flat- and high-trajectory weapons to deliver projectiles to a target. Consider nuclear weapons when applicable.

(3) *Concealment.* Determine the capability of the terrain to provide concealment for men, equipment, and installations. Consider the effect of terrain on concealment by artificial means.

(4) *Cover.* Determine the capability of the terrain to provide cover for men, equipment, and installations. Consider the problem of cover from flat-trajectory, high-trajectory, and nuclear weapons when applicable.

(5) *Obstacles.* Determine the capability of the terrain to delay the advance of military forces or impede military operations. Consider both natural and manmade obstacles.

(6) *Movement.* From an analysis of soils trafficability, natural and manmade obstacles, and existing routes of movement, determine the ability of troops and equipment to move through an area. Use standard color code to describe movement conditions. Use specific terms of movement whenever possible; i.e.—vehicular, cross-country, and foot.

(7) *Key terrain features.* From an analysis of the terrain and of friendly and enemy methods of operations, indicate those terrain features which appear to be critical, such as a dominant height, a highway, a communication center, or an airfield.

(8) *Avenues of approach.* From an analysis of all terrain factors affecting capabilities to move men and materiel, determine the avenues of approach to the objective. Consider existing routes of movement, possibilities of cross-country movement, and amphibious or airborne or airmobile operations when applicable.

b. Engineering Aspects of the Terrain. Determination of the following military aspects is essential to planning the engineer phase of operations. Include these items in written or graphic form as overprints or overlays.

(1) *Construction sites.* From an analysis of surface material and other terrain factors, determine areas suitable for construction of roads, airfields, buildings, underground installations, surface defensive installations, or others.

(2) *Construction materials.* From an analysis of surface materials and other terrain factors, determine the probable location of rock, gravel, sand, or other natural construction material.

(3) *Water supply.* From an analysis of the drainage system and subsurface formations, determine the probable location of potable water and water suitable for construction use.

4. Maps and Charts (as appropriate)

a. Topographic.

b. Trafficability.

c. Landing (where applicable).

d. Special maps (when needed).

(1) *Geological.*
(2) *Soils.*
(3) *Hydrographic charts.*
(4) *Town plans.*
(5) *Road.*
(6) *Joint operations graphic.*

APPENDIX C

SAMPLE TERRAIN STUDY

Headquarters 15th Army
Western Germany
January 1945

1. PURPOSE AND LIMITING CONSIDERATIONS

a. Purpose. This terrain study considers the area to the south and east of COLOGNE, Germany, for February and March. General boundaries for the zone are the towns of JULICH on the ROER RIVER (3145) and ZULPICH (3418), and the RHINE RIVER north and south of COLOGNE as shown on inclosure 1 (fig. 61). Elements of Fifteenth Army, consisting of armored and infantry units, are located west of the ROER RIVER and presumably will operate in the area with the general mission of advancing northeastward to the RHINE RIVER.

b. Limiting Consideration. Information presented is based on data obtained from maps, intelligence documents, climatic study, and interrogation. Ground reconnaissance has not been made, nor have the effects of bombing been considered.

2. GENERAL DESCRIPTION OF THE TERRAIN

a. Synopsis. The area during this period of the year provides favorable conditions for military operations. It is highly populated mixed farm and industrial region. Construction sites and materials are available and the communication system is excellent. Movement across the RHINE RIVER is canalized at BONN and COLOGNE. Obstacles are the ROER and ERFT RIVERS and the VILLE RIDGE. Conditions influencing movement are sensitive to precipitation.

b. Climate Conditions. See inclosures 2, 3, and 4 (figs. 61-64).

(1) *Temperatures* will present problems to the effective operation of troops in the field. Inclosures 2, 3, and 4 give compiled temperature data.

(2) *Precipitation* in some form normally occurs every second day. Wet soils are common. Snowfalls ordinarily do not exceed 9 to 11 centimeters (6 or 7 inches). Ice, if present, is thin and will not support a man.

(3) *Wind* direction and velocity are given by the wind roses in inclosures 3 and 4. Winds from the east are usually accompanied by severe temperature drops.

(4) *Visibility* factors are listed in inclosures 2, 3, 4 and 5. Fog occurs rarely at this time of year, despite the high relative humidity. The high frequency of moderate to fresh winds favors the formation of low clouds rather than fog.

c. *Topography.*

(1) *Relief* is low and gently rolling with only two exceptions: the southwestern portion of the map (HOHE VENN) has steep wooded hills and highlands dissected by deep valleys; and a low hilly ridge, hereafter known as the VILLE RIDGE, exists between the ERFT RIVER and the RHINE RIVER. This area is discussed in detail on the back of the map and later in this study.

(2) *Drainage.* Streams cross the region generally from southeast to northwest. The ROER RIVER is approximately 80 feet wide, with no fords, and *can be flooded by release of water impounded in dams to the south.* The ERFT RIVER, or canal, meanders through several channels in its flood plain. These channels average 6 to 9 meters (20 to 30 feet) in width and .6 to 1.5 meters (2 to 5 feet) in depth. In many places, the river channels are flanked by marshy flats which are drained through numerous deep ditches.

(3) *Vegetation.* The area is largely devoted to agriculture and pasture but scattered forests do exist, and these are delineated on the map with notes as to density, type, and approximate boll size. Trails and unimproved roads allow restricted passage even through the dense forests. At this period of the year, the ground will be fallow or in low cover crop which will increase its trafficability. Trees are scattered throughout the numerous mine pits in the area.

(4) *Surface materials.* The region is generally covered by a loamy soil tending toward sandy soil in the south. In the VILLE RIDGE area, the original soils have been stripped off during mining, exposing sandstone and shale. Stream valleys are composed of fine grained silts in the northern reaches and change to sandy material upstream to the south. The soil immediately west of the RHINE RIVER is composed of sandy well-drained material. Surface materials are discussed further on the back of the movement map.

(5) *Manmade features.* The manmade features studied include roads, railways, bridges, airfields, towns, and strip mines.

(*a*) An excellent network of roads exists. Only the primary system, that with a route classification (FM 5–36) of X is shown on the map. In addition, secondary roads of general route classification connect many of the villages. Free egress from roads for cross-country movement is possible in most places.

(*b*) Rail communication, as shown on the map, is very good. As a a supplement to the standard-gage system, considerable narrow-gage lines exist, particularly in the VILLE RIDGE region. Marshalling yards are located at DUREN, BONN, and COLOGNE. The tunnel on the double-tracked route between DUREN and COLOGNE is a vulnerable point, but may be bypassed through alternate routes.

(*c*) The classification of bridges along the primary-road system is 65. Important bridges are indicated on the map with the classification noted if lower than the general class. Bridges on the secondary-road system have a general classification of 55.

(*d*) This area contains a large municipal airfield capable of handling heavy-cargo aircraft. These have been marked on the map. Also shown are three landing strips which can be used by assault aircraft. Sections of primary roads and autobahns may be utilized for light Army aircraft strips.

(*e*) Most urban areas are well built-up with stone and masonry buildings. Streets, except for boulevards or freeways, are narrow, and may permit only one-way traffic to trucks and tanks. All but the larger cities may be bypassed easily.

3. MILITARY ASPECTS OF THE TERRAIN

a. Tactical Aspects.

(1) *Observation.* Observation throughout the area is generally good, although there are small areas of defilade. The VILLE RIDGE affords excellent observation of the lowlands to the east and west. The HOHE VENN area provides good points for observation of the ROER RIVER valley. Small hills afford tactical observation in the plains section. Aerial observation will be excellent, except where woods obscure the ground.

(2) *Fields of fire.* The area provides generally good fields of fire for all weapons with two exceptions. The broken terrain of the VILLE RIDGE and the HOHE VENN limits fields of fire for flat-trajectory weapons within the ridge masses themselves. However, flat-trajectory weapons situated on these ridges can command their lowland approaches very effectively.

(3) *Concealment.* The mixed forested areas give good concealment from both air and ground observation. The broadleaf forests are bare of leaves during February and March and offer only limited concealment. Farming practices in this part of Germany are such that little concealment is possible in the winter cover crops, but the many farm buildings and small villages afford good concealment for small units.

(4) *Cover.* Principal cover is offered by the stone structures that make up the cities and farm communities. In the VILLE RIDGE area, some cover can be found in the mine tunnels.

(5) *Obstacles.*

(*a*) The ROER RIVER under normal conditions will offer only minor problems to an assault crossing. Opening or destroying the ROER DAM will flood the ROER VALLEY. If this is done, it will take at least a week for the ROER RIVER to recede, and 2 to 3 weeks for soils trafficability to return to normal.

(*b*) The ERFT VALLEY, with its drained swamps and many canals, will restrict movement to roads in most areas. The river channels themselves are not a serious obstacle to infantry; however, a long thaw, which is quite possible in March, or an unseasonal rain can make them unfordable to foot troops. There are also lignite pits west of Koln along Erft River.

(*c*) Wooded areas may restrict vehicular movement to narrow unimproved roads but are passable for infantry under normal conditions.

(*d*) The VILLE RIDGE forms an obstacle of major importance to vehicular and foot movement. It may be easily defended against

a superior force, affording the defender excellent observation and concealment in its woods and extensive mine workings.

(6) *Movement.* This is indicated on the movement map (fig. 61). The area as a whole provides very good movement during dry weather, and fair to doubtful movement during periods of heavy precipitation.

(7) *Key terrain features.*

(*a*) The VILLE RIDGE dominates the lowlands to the east and west of the hill mass. Routes crossing the VILLE RIDGE are restricted to the roads because of the extensive pits, quarries, and spoil heaps left by coal-mining operations.

(*b*) The HOHE VENN highlands southwest of DUREN overlook the adjacent ROER RIVER valley. In this region heavy forests and steep slopes restrict vehicular traffic to the roads.

(8) *Avenues of approach.* The main highways from the ROER RIVER toward COLOGNE offer good avenues af approach from the southwest, and represent the bet routes for breaching the VILLE RIDGE. The *best* avenues of approach would be to the north of JULICH-COLOGNE highway where the VILLE RIDGE may be flanked and cut off. The secondary road and rail net is adequate for support of an armored attack. The VILLE RIDGE may be flanked from the south in the vicinity of BONN, but here armored operations will be somewhat restricted and canalized by dense forests, and by the constriction of the corridor between the VILLE RIDGE and the RHINE RIVER.

b. Engineering Aspects of the Terrain.

(1) *Construction sites.* With the exception of the mining dumps, the southwestern highlands, and the river flood plains, the area is well suited for the construction of roads, airfields, cantonments, depots, and other military surface structures. The land is level and open, the communication net is excellent, and the soil has good stability and bearing capacity. The HOHE VENN highland is better suited for underground facilities than the plains area. Solid sandstone layers are useful as floors and roofs here, and ground water will not be as troublesome as in the flatlands.

(2) *Construction materials.*

(*a*) *Natural materials.* Quarries and gravel banks are available for stone and aggregate at many places. The terraces along the RHINE and ROER RIVERS are good sources of gravel and sand, while sandstone suitable for construction purposes can be quarried west of ZULPICH. Broken rock consisting of sandstone, shale, and soil is piled in the VILLE RIDGE dumps, and west of DUREN. Forests supply adequate quantities of standing timber to cover any foreseeable needs. Small local sawmills may be useful in cutting the timber for use.

(*b*) *Manufactured materials.* The heavy industrial buildings in the VILLE RIDGE and COLOGNE areas are good sources of construction steel, lumber, and similar materials needed by engineers. In addition, a large network of mine railroads exists throughout the pits and may be utilized for material.

(3) *Water supply.* An adequate field water supply may be obtained from the streams and wells of the area. Civilian water supply on farms is obtained from wells, and in cities through municipal distribution plants and systems which draw water from the major rivers. Emergency water supplies may be drawn from these sources.

5 Inclosures:

APPENDIX D

SAMPLE CLIMATIC STUDY

General

This study is divided into four parts, each having a different operational aspect: amphibious, airborne, airmobile, and overland in two differing climatic regions. The studies and accompanying data do not refer to any exact geographic locations, but are offered only as a guide for format and content.

a. Information Sources. Source material for such studies is usually drawn from climatic summaries on file at the Climatic Center, Headquarters Air Weather Service, from the National Intelligence Survey (NIS) sources, and from weather summaries on file at the U.S. Weather Bureau or Congressional Libraries. In the field, information of a climatic nature may be obtained from local Air Weather Service detachments or a national meteorological service office. The climatic study is designed to provide a first estimate of weather factors affecting military operations and should not be regarded as an operational forecast which normally is supplied by other Air Weather Service detachments.

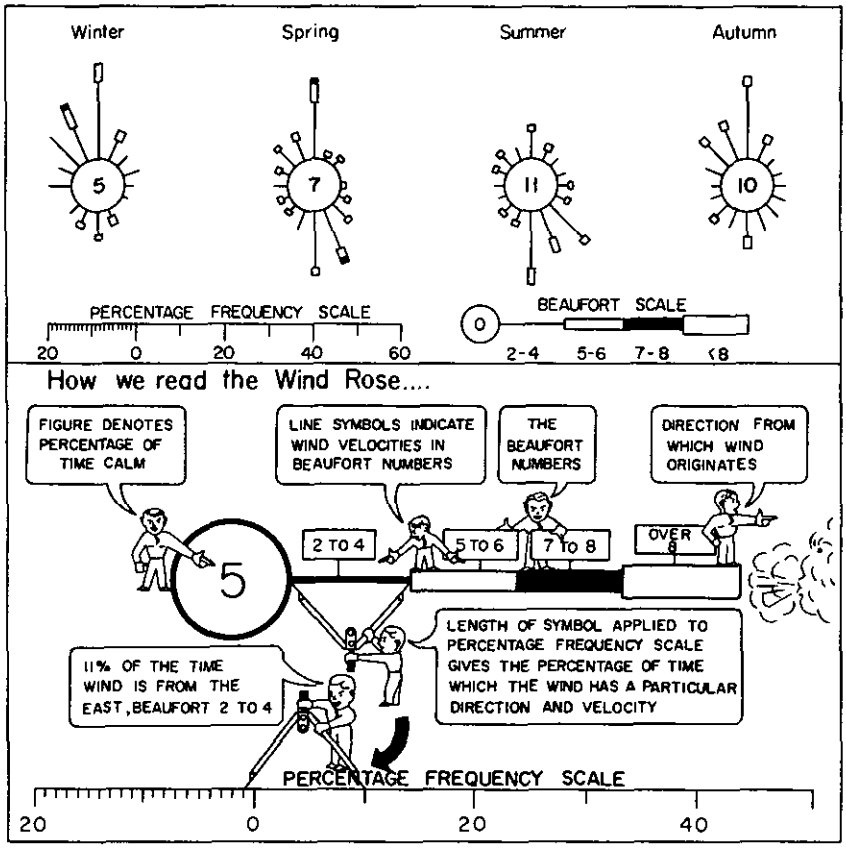

Figure 65. How to read a wind rose.

b. Wind Rose. The agency requesting climatic data from Air Weather Service should specify whether the wind speed data is desired in kilometers, miles, or knots per hour. Wind speed data is shown in compact form by means of a wind rose. The method used to read a wind rose is shown in figure 65. The wind rose makes use of the Beaufort scale, which is a wind scale in which the force of the wind is indicated by numbers with corresponding descriptive terms. These terms are commonly used by the U.S. Weather Bureau (table 1, chap. 4).

Part I

Climatic Factors Affecting an Overland Operation in the Region Surrounding OBJECTIVE ONE During May

In terms of general climate, OBJECTIVE ONE area has a maritime-type climate, characterized by cool, humid winters and mild, comparatively dry summers. The month of May represents a portion of the transition period between these two characteristic seasons.

In the absence of meteorological information for the exact location involved, combined data from adjacent areas, both north and south, were considered to be representative of the climate of OBJECTIVE ONE area and are presented as appendix material in tabular (table D–1) and graphical (fig. 66) form.

Table D–1. Overland Operation OBJECTIVE ONE—May

Temperature (°F.):	
Mean Maximum	62
Mean	50
Mean minimum	38
Recorded Extremes	77 to 31
Mean Number of Days with:	
Fog	1
Thunderstorms	0
Rain	8

Temperature during May is usually conducive to moderate to strenuous activity. Normally, temperature averages approximately 50° F., with a moderate diurnal and monthly range. Minimum temperatures, especially during the first portion of the month, in valley areas or close to the ground surface are frequently in the mid 30's during early morning hours.

Rainfall is light, averaging 5 to 6 centimeters (2 to 2½ inches) for the month. This amount, well distributed in time (the maximum reported for any 24-hour period is 2.5 centimeters (1½ inches)), should not create problems associated with soil moisture and would be sufficient to minimize dust conditions. Snow accumulations on the mountains and passes east of the area melt at this time and provide a source of fresh water for the local streams. Flooding of these streams is unusual.

Relative Humidity is high throughout the day, averaging 80 percent to 85 percent. Diurnally, the variation is relatively small, 10 percent to 20 percent. Although relative humidities average quite high, the incidence of fog and other forms of restricted visibilities is quite low; about 5 percent of the time the visibility is less than 4 kilometers (2½ miles).

Cloud cover and visibilities are well suited for tactical air support.*

Winds are primarily from a westerly direction, southwest through northwest, with an average speed of 7 to 10 knots. Approximately 25 percent of the time the winds are less than 3 knots.

* Minimum ceiling and visibility requirements depend upon the type of support and the equipment involved, and upon the type of terrain over which this support must operate.

CLIMATIC DATA FOR OBJECTIVE ONE

MAY

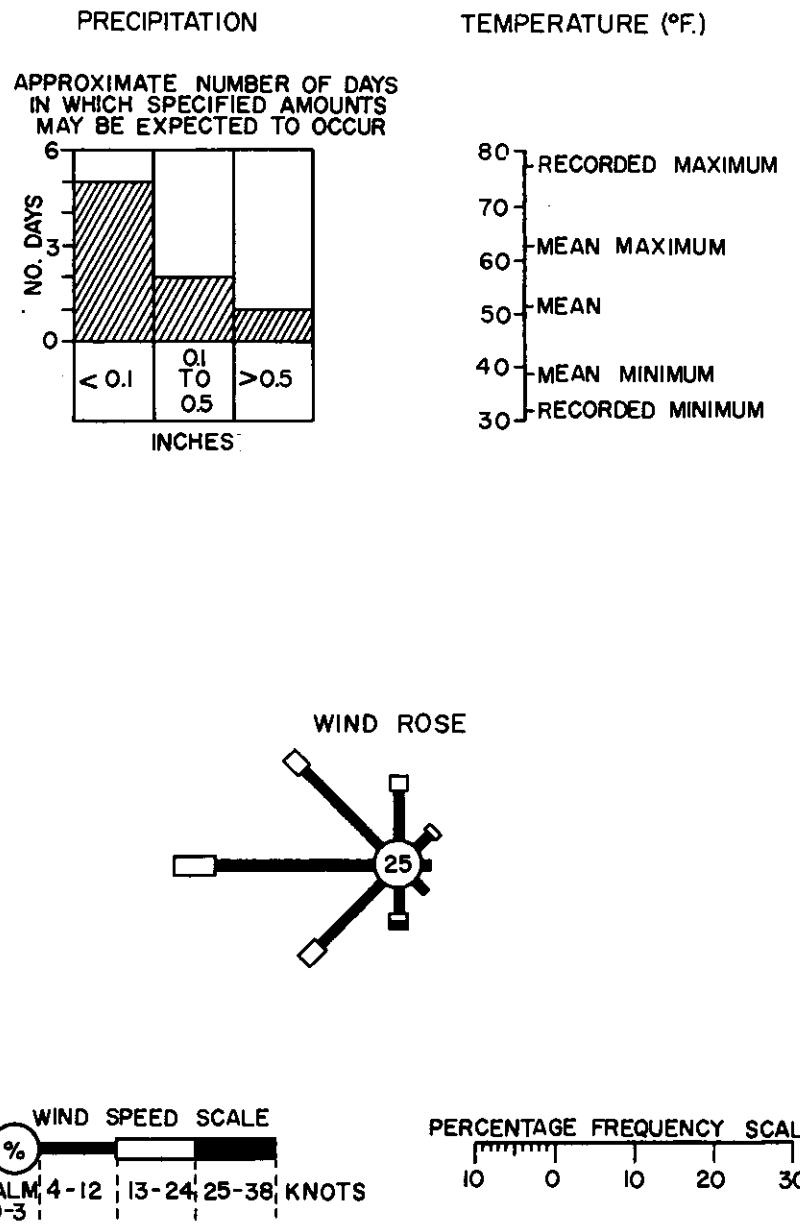

Figure 66. Climatic data for OBJECTIVE ONE—May.

Part II

Climatic Factors Affecting an Amphibious Landing on OBJECTIVE TWO During May or June

Complete meteorological observations on the island were made only during a brief period during World War II. Plantation records for longer periods of record have been used in arriving at precipitation estimates. Climatic data are presented as appendix material (table D–2 and figs. 67 and 68).

Table D–2. Amphibious Operations OBJECTIVE TWO Island—May and June

	May	June
Temperature (°F.):		
Mean Maximum	88	90
Mean	81	82
Mean Minimum	75	76
Recorded Extremes	93 to 73	95 to 74
Mean Number of Days with:		
Thunderstorms	8	6
Precipitation	17	12
1.3 centimeters— 0.5 inch	12	9
4.8 centimeters— 0.6 to 1.9 inches	4	2
5 centimeters— 2.0 inches	1	1

Climatically, OBJECTIVE TWO Island has all the typical tropical characteristics with heavy, shower-type rainfall and a small diurnal and seasonal temperature range. Since the island is affected by the monsoon wind, the May-June period is one of transition, during which winds are normally light and variable.

Temperature conditions are not conducive to human activity, and the daily range of temperatures is insufficient to alleviate this human discomfort at night. The mean temperature is approximately 80° F., with a maximum daily range of about 20 Fahrenheit degrees.

Humidity is constantly high and coupled with the warm temperatures creates problems of material storage and supply, in addition to adding to human discomfort. Mean relative humidity is approximately 80 percent, with only slight variation diurnally.

Visibility is seldom restricted by weather factors except during brief periods of heavy shower activity; however, dense vegetation limits ground visibility severely unless some form of clearing has taken place.

Precipitation is of the brief, heavy shower-type that usually occurs during the afternoon on an average of 1 out of 2 days. Thunderstorms are quite frequent, with an average of 8 storms per month. Although total precipitation is highly variable from year to year, it is more than adequate to keep soils moist, support heavy vegetation, and present vehicular transport problems. Maximum precipitation in 24 hours reported for the island during this period was 18 centimeters (7.2 inches) during May.

Winds are light and variable, except during heavy showers; however, during June the southeast monsoon is being established and southeast winds become more predominant. In the forested areas, winds are usually very light or calm, but along coastal strips they average about 5 knots. Typhoon winds are not considered a threat to operations this early in the season.

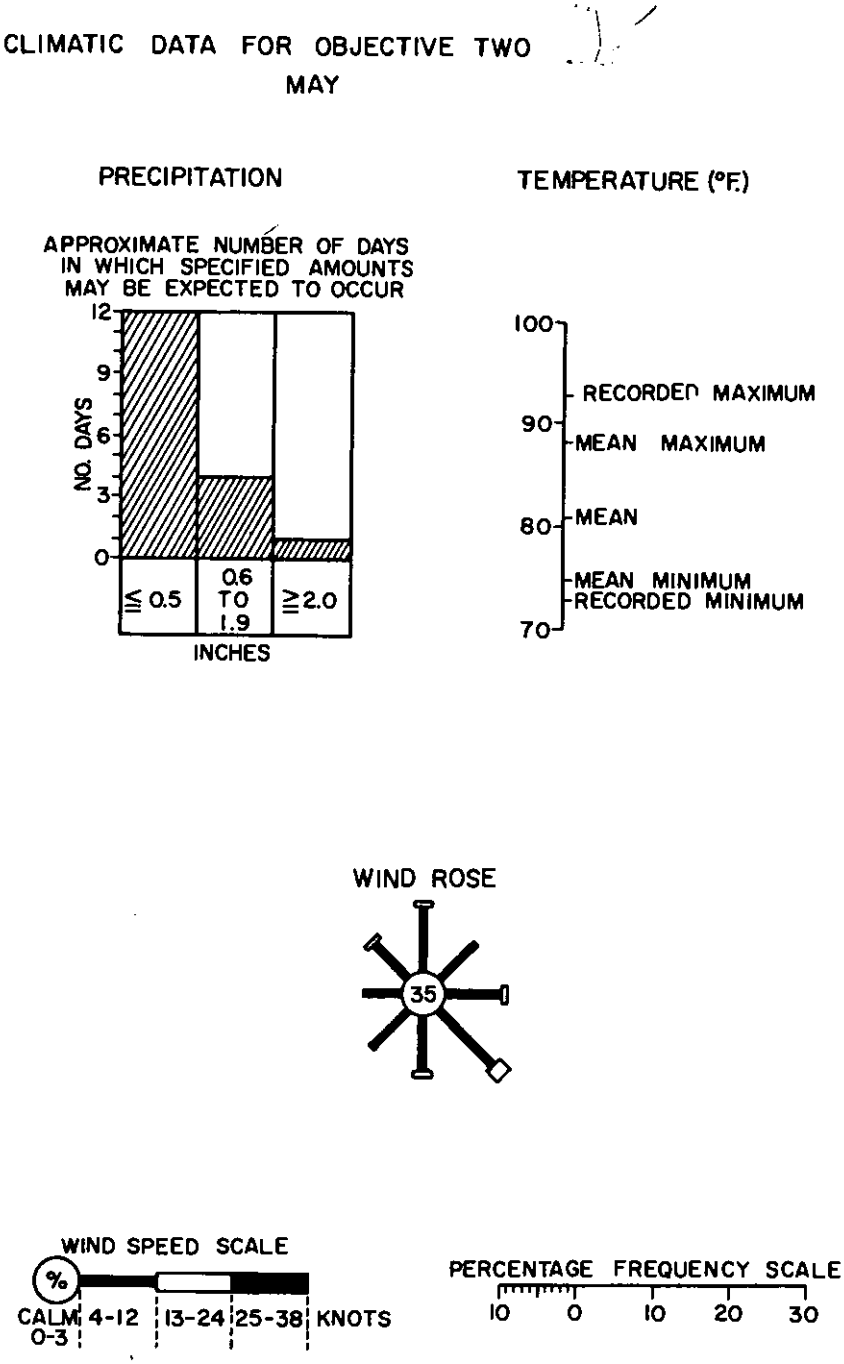

Figure 67. Climatic data for OBJECTIVE TWO—May.

Part III

Climatic Factors Affecting an Airborne-Airmobile Operation in the Vicinity of OBJECTIVE THREE During September

For the purposes of this report, it was assumed that paratroop operations would be carried out only with a ceiling value equal to or greater than 305 meters (1,000 feet), visibility equal to or greater than 4 kilometers (2½ miles), and wind speed less than 13 knots. On this basis, favorable weather occurs most frequently during the midafternoon. Unfavorable

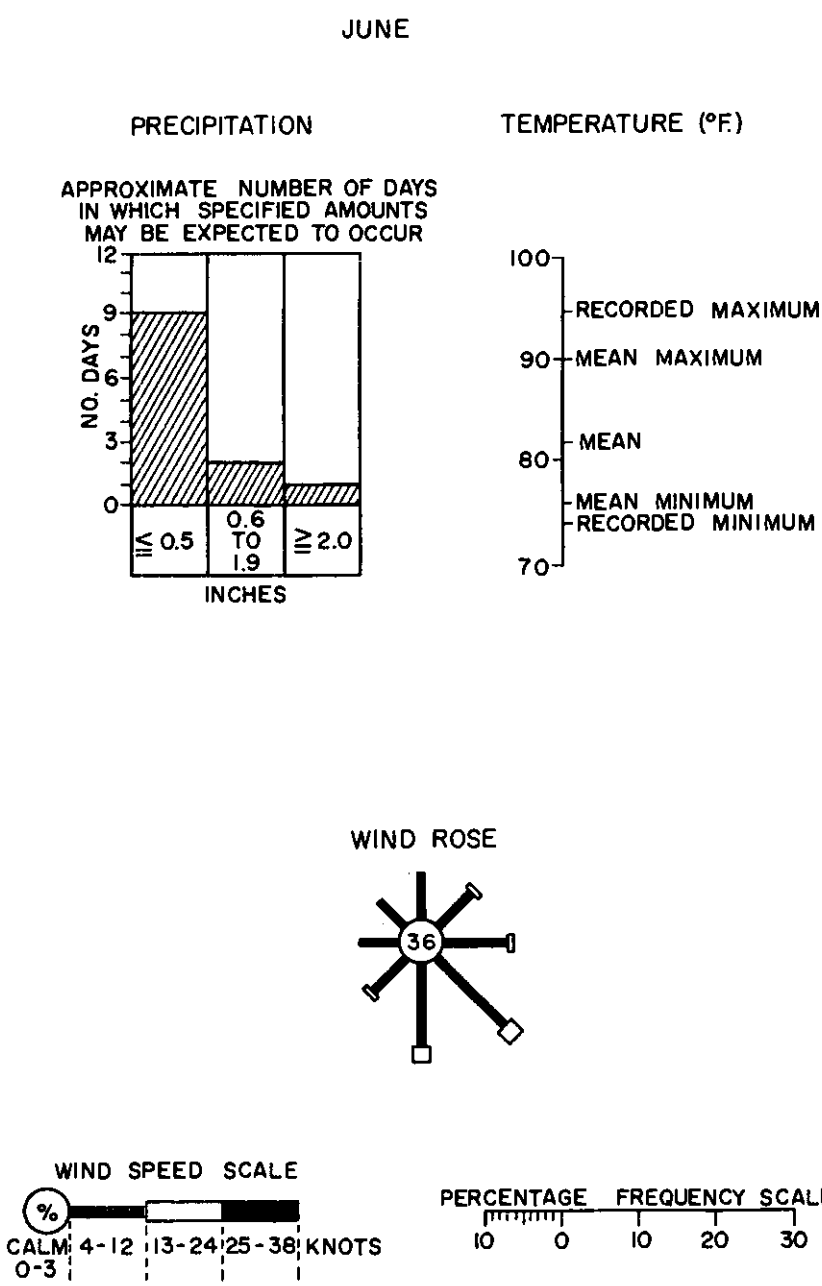

Figure 68. Climatic data for OBJECTIVE TWO—June.

conditions increase gradually until early morning hours when adverse weather occurs approximately 25 percent of the time. Tactical air support, depending upon the type needed and equipment utilized, should be able to operate 70 percent to 80 percent of the daylight hours (table D–3 and fig. 69) .

Table D–3. Airborne Operation OBJECTIVE THREE—September

	September
Temperature (°F.):	
Mean Maximum	67
Mean	58
Mean Minimum	50
Recorded Extremes	87 to 38
Mean Number of Days with:	
Thunderstorms	3
Precipitation	19
2.54 millimeters (0.1 inch)	9
2.54 to 12.70 millimeters (0.1 to 0.5 inch)	6
12.70 millimeters (0.5 inch)	4
Precentage Frequency, by Hour, of Weather Favorable for Paradrop Operations (Ceiling 305 meters (1,000 ft.)), Visibility 4 kilometers (2½ miles, Wind 13 ft.)	
0800 LST 74%	
1400 LST 96%	
1900 LST 91%	

Temperatures are not extreme during this period and should not present problems of human comfort. The extreme range of temperature is large, but normal temperatures are quite moderate with mean maximum of 67° F. and a mean minimum of 50° F.

Precipitation, in the form of drizzle, light rain, or showers, occurs on the average of 2 days out of 3, giving an average September rainfall amount of approximately 6.35 centimeters (2½ inches). Heavy rainfall is infrequent, but when it occurs, poorly drained areas become flooded and trafficability problems are intensified.

Fog restricts visibility to less than 800 meters (one-half mile) on 1 day of 10, most often during the early morning hours. During the afternoon and early evening the possibility of restricted vision caused by air pollutant is even less.

Winds are most frequently from the northwest (see wind rose), with about 10 percent of the observations showing wind speeds greater than 13 knots. Diurnal variations in wind strength or direction appear negligible in this particular area.

Part IV

Climatic Factors Affecting an Overland Operation in the Vicinity of OBJECTIVE FOUR During February

Climatically, the objective area has a marine climate, which implies mild, cloudy, and humid weather (table D–4 and fig. 70).

Table D–4. Overland Operation OBJECTIVE FOUR —February

	February
Temperature (°F.):	
Mean Maximum	45
Mean	38
Mean Minimum	32
Recorded Extremes	64 to 10
Mean Number of Days with:	
Precipitation	16
2.54 millimeters (0.1 inch)	8
2.54 to 12.70 millimeters (0.1 to 0.5 inch)	5
12.70 millimeters (0.5 inch)	3
Snowfall	5
Snow on ground	5
Mean Relative Humidity (%)	
0700 LST	85
1400 LST	71
1900 LST	80

Temperatures usually are not severe, as a result of the moderating effect of the water on the migratory air masses. However, alternate freezing and thawing of the normally water-soaked soil surface is common, creating problems of vehicular movement due to rapid deterioration of natural surfaces.

Precipitation in the form of rain, drizzle, and/or snow occurs on approximately one-half of the days during the month. Snowfall is usually small in amount, but is apt to be wet, heavy, and clinging; possibly resulting in destruction of overhead wires and some vegetation. Snow cover is usually shortlived, being destroyed by the frequent warmer rains. Soils are usually water soaked; only during exceptionally cold winters does the ground freeze to any depth.

Fog occurs on 4 to 5 days during the month and is usually quite dense, persistent, and widespread, restricting visibility to several hundred meters and precluding any tactical air support. Cloud cover is usually present, but

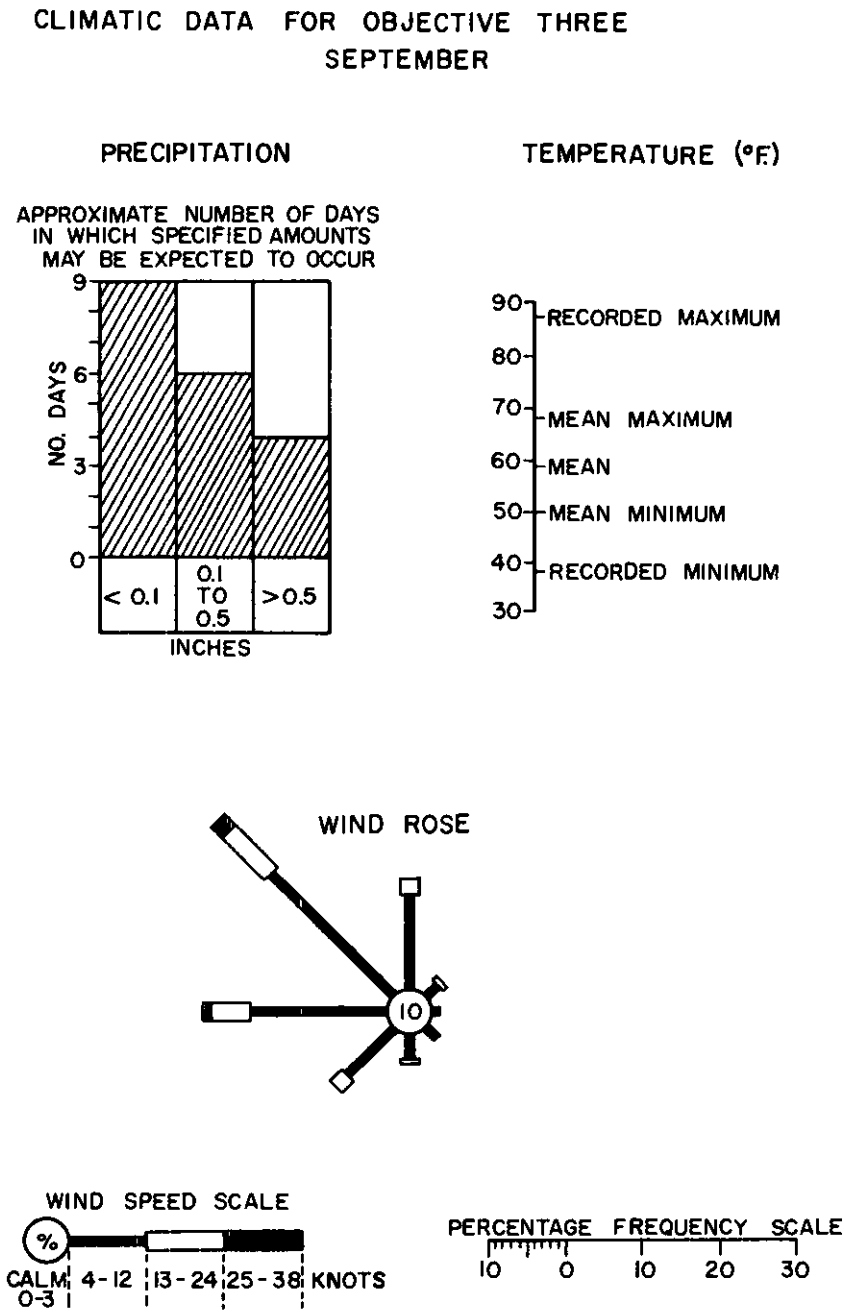

Figure 69. Climatic data Objective Three—September.

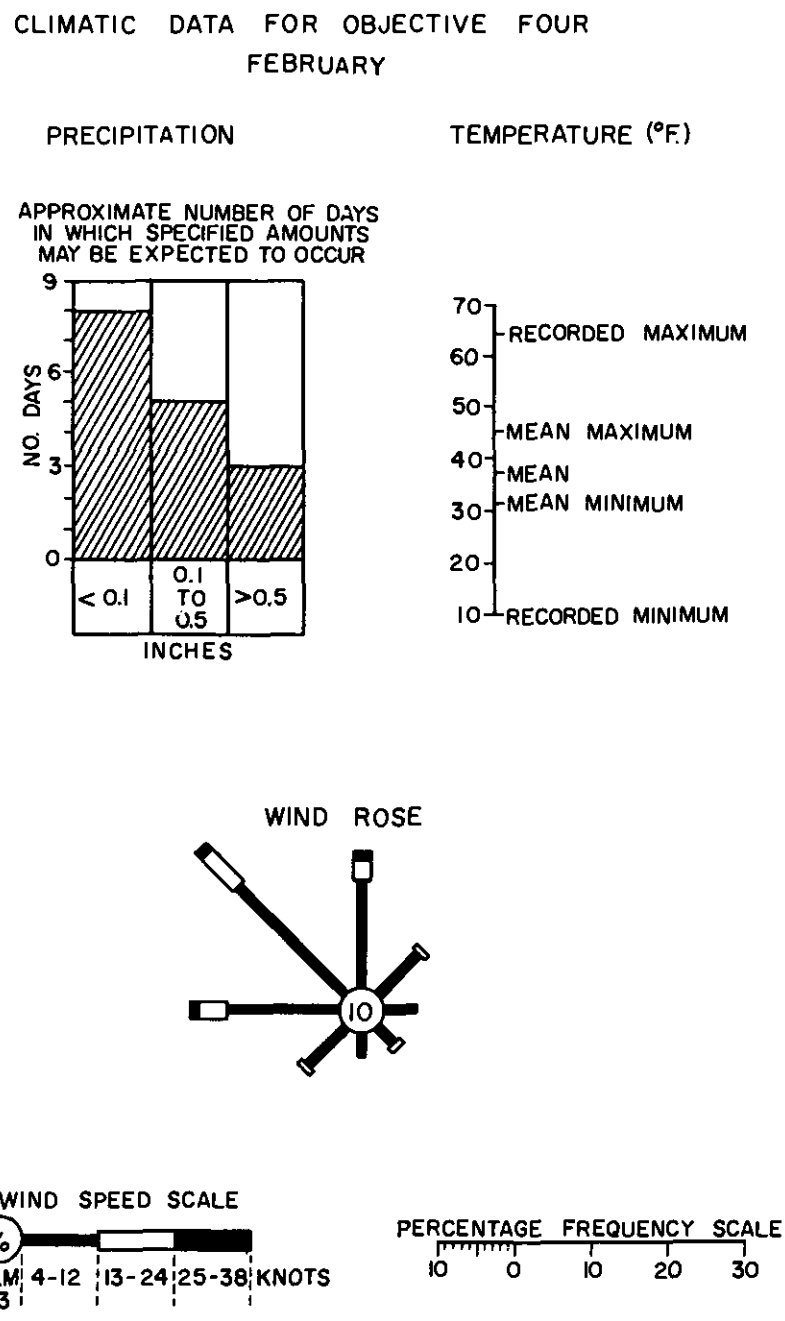

Figure 70. Climatic data for OBJECTIVE FOUR—February.

normally the effective ceiling is about 610 meters (2,000 feet).

Winds are predominately from a northwestern direction, light to moderate in force with infrequent gale-force winds associated with strong frontal passages.

APPENDIX E

NATURAL TERRAIN FEATURES

The natural terrain features shown in A, B, and C, figure 71 will serve as a guide to producers and users of terrain studies. A few of the terrain features identified on the figure may be known in some regions under different names because of local usage.

APPENDIX F

DEPARTMENT OF DEFENSE INTELLIGENCE INFORMATION REPORT FORMS 1396 AND 1396C

Department of Defense intelligence information will be reported on DD Form 1396 and DD Form 1396c. These forms are available through regular supply channels.

By Order of the Secretary of the Army:

HAROLD K. JOHNSON,
General, United States Army,
Chief of Staff.

Official:

KENNETH G. WICKHAM,
Major General, United States Army,
The Adjutant General.

Distribution:

To be distributed in accordance with DA Form 12–11 requirements for terrain intelligence.

☆ U.S. GOVERNMENT PRINTING OFFICE: 1967–0 273–544

MOVEMENT MAP COLOGNE AREA

This sample movement map is not to scale

Sample Movement Color Key

- Good movement under all conditions.
- Good movement in dry weather, fair during wet weather.
- air movement under ll conditions.
- Fair movement in dry weather; poor to doubtful in wet weather
- Poor movement under all conditions.
- Extremely poor movement under all conditions.
- Green hachures indicate passable routes through areas of poor movement.
- Red hachures indicate impracticable obstacles.

Specific Movement Key

- Mountains and steep hills generally wooded. Travel restricted to the few existing roads. — 1
- Gently sloping and level land; slopes less than 10% sandy or gravelly soil; good movement in all but worst weather. — 2A
- Gently sloping and level land; slopes less than 10% loamy or clayey soil; good movement in dry weather, hampered by mud in wet weather. — 2B
- Gently sloping and level land, urban area. Traffic restricted to streets. — 2C
- Wooded areas. Density, type and thickness of trees given on map and these factors determine practicability of passage. — 3
- Drained swamps and flood plains; many canals and ditches. Disruption of canal drainage causes flooding. Generally untrafficable. — 4A
- Mine pits and spoil heaps. Untrafficable because of steep slopes and holes. — 4B
- Swamps. Impracticable. — 5

LEGEND

- Woods
- Railway, multiple track (with tunnel)
- Railway, single track
- Landing strip, light aircraft
- Highway, autobahn, route class 40 ft. × 65 T
- Highway, primary, route class 20 ft. × 55 T
- Highway, state, route class 20 ft. × 55 T
- Bridge, railroad or highway
- Stream, canal, and river
- Airfield, large municipal
- Escarpment and mining pits

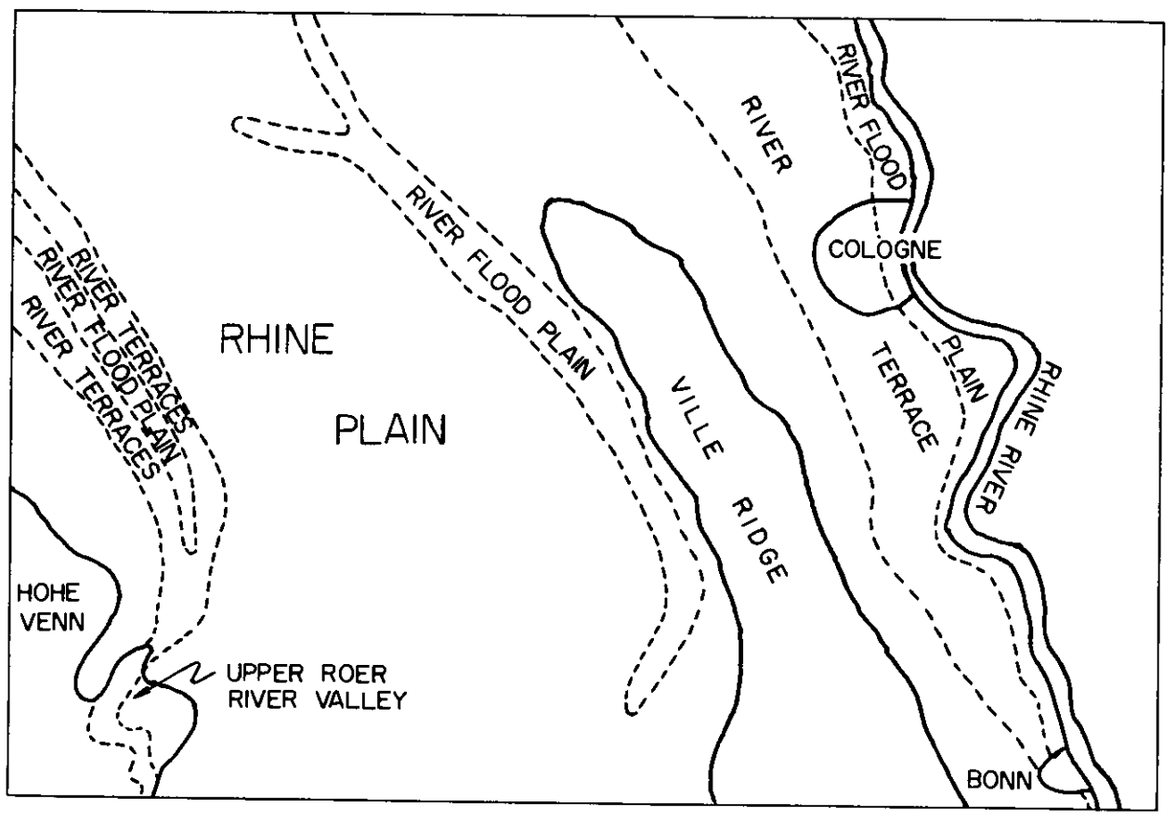
Prepared by The Engineer School, Fort Belvoir, 1959. Map keyed to Germany 1:100,000 AMS, S-1 and R-1, 1952, to which reference is made for marginal information. Comments concerning field usability are requested by The Department of Training Publications, The Engineer School, Fort Belvoir, Virginia. For illustrative purposes, bridge classification information has been purposely omitted from this map. Route classification information has been added to the legend under "roads".

Figure 61. Movement Map of Cologne area.



HOHE VENN HIGHLAND

The HOHE VENN HIGHLAND shown on the map is the northern tip of a much larger forested plateau to the southwest. It has two principal landforms . . . a dissected upland and the upper ROER RIVER valley system.

Upland

This upland is made up of flattened sandstone hills 300–500 feet high with steep wooded slopes usually above 25 percent. Bluffs are common. Some of the flattened hilltops are open and are used for farming and pasturage. Principal soil type is loam. Cross-country movement is good in the open areas, but steep sandstone-shouldered ravines are frequent barriers. Trails and roads provide occasional passage from the open hilltops through defiles to the lowland valleys. In this area, sandstone may be quarried. Towns are small and scattered, and construction sites for facilities are limited. Road and rail communication is poor as compared to the lowland plains.

Upper ROER RIVER Valley

This valley system is rather narrow with steep wooded sides and occasional escarpments. The valley floor does not exceed one-half mile in width but is made up of sandy gravel; cross-country movement is good under most conditions. The ROER RIVER is approximately 80 feet wide in this vicinity, with a stream velocity of 4-8 ft/sec. Two large dams several miles upstream control its flow and much of the valley floor may be flooded by release of the impounded water. Traffic into and out of the valley is restricted to roads, but a railroad follows the river route into the city of DUREN.

VILLE RIDGE

The VILLE RIDGE is a long (25 miles), narrow (3-5 miles), southward rising promontory with summits 100 to 250 feet above the surrounding countryside. Surface soil type is clay loam with sand loam along the flanks of the ridge, but the overburden is rarely in sight due to extensive surface coal mining. The mine pits, dumps, and spoil heaps, and the great number of industrial buildings effectively limit vehicular movement to roads. Scattered mixed and broadleaf forests are found throughout the ridge and are indicated on the map. Crushed rock is available in the mine dumps. Several coal-driven power generating stations are located here. The ridge area is unfit for airfield sites because of mines, industrial towers, buildings, woods, and so on.

RHINE PLAIN

The RHINE PLAIN consists of three related areas; (1) flood plains of the lower ROER, ERFT, and RHINE RIVERS; (2) the terraces along these rivers; (3) the prairie lands between the rivers.

Flood Plains

The flood plains of the ROER and ERFT RIVERS are quite flat and are dissected by many ditches and drainage channels. They have complex soils of silts and very fine sands; a high water table makes them difficult to traverse during wet periods. Portions of the flood plains are drained swamps with considerable organic material in the soil. Traffic is restricted to the road system by these factors, but foot troops will encounter only minor difficulty. The flood plain of the RHINE RIVER is quite narrow, as the river terraces closely approach the river on the west bank between BONN and COLOGNE. The RHINE RIVER here is 900-1400 feet wide, has a 2-4 ft/sec. velocity and is 20-40 feet in depth.

River Terraces

River terraces are poorly developed along the ROER and ERFT RIVERS, but reach a grand scale along the RHINE RIVER where four or five terraces can be found. They are composed of sandy or occasionally loamy soil, and are up to four miles wide along the west bank. Cross-country movement is good to excellent in most weather. Slopes between terraces are usually less than 10 percent, while the terraces themselves are practically level. One boggy spot (5) is shown between COLOGNE and BONN, but others, all of very small size, may be present on the southwestern outskirts of COLOGNE. Terrace slopes along the ROER and RHINE RIVERS are good sources for gravel aggregate.

Prairie Lands

These are extensive areas of very gently rolling topography mostly taken up with farmland. The land between the ROER and ERFT RIVERS, and that north of the JULICH-COLOGNE highway are examples of prairie lands. Soils are sand loam to clay loam, rather thick, and are the weathered product of loess deposits. Sandy areas are found, and are due partly to glacial outwash, and partly to the lithology of the underlying rock. Cross-country movement over prairie land is good in fair weather, but hampered by mud to a degree dependent upon the sand content of the soil. Scattered wooded areas which usually possess soils of the same loamy nature are delineated on the map. Prairie lands are well suited for most types of military surface construction.

GENERAL WEATHER-MOVEMENT RELATIONS

Although February and March are months low in total precipitation, weather conditions cause soil to retain a high moisture content. Alternate freezing at night and thawing during the day prevents normal drainage. Freezing is seldom intense enough or of such a duration to facilitate movement. The snow cover normally does not exceed six or seven inches at any one time, which will not hinder tracked vehicles but may necessitate the use of chains on wheeled vehicles. Good cross-country movement may be counted on for no more than eight or nine days per month in the prairie lands during this period of the year.

PART ONE
ELEMENTARY MILITARY CRYPTOGRAPHY
CHAPTER 1
INTRODUCTION

Section I. GENERAL

1. Scope

This manual consists of two parts as follows:

a. Part one is an introduction to the elementary principles of military cryptography. In this part a few typical examples of cipher systems and code systems are presented; the procedure in cryptographing and decryptographing by means of the systems is shown in detail; methods of preparing keys suitable for use in connection with them are illustrated; errors and their correction are discussed; and finally, a few of the most important precautions to be observed in safeguarding systems and cryptograms from enemy cryptanalysts are set forth. Only such considerations as apply to military cryptography are included.

b. Part two develops the principles established in part one and treats of the more advanced systems. Following the presentation sequence of part one, transposition systems are discussed first, then substitution systems. Considerable attention is devoted to combined substitution and transposition methods. Following this is a description of a limited number of cipher devices and machines, together with a discussion of their present-day limitations. Finally, code systems are discussed briefly with special emphasis upon enciphered code systems.

2. Developments in Cryptography

a. Cryptography is by no means a static art or science and viewpoints are always undergoing change; what is regarded as wholly impracticable today may, through some unforeseen improvement in technique, become feasible tomorrow, and it is unwise to condemn a system too hastily. For example, before World War I, and indeed for the first 2 years of that conflict, the use of codebooks in the theater of operations was

REF ID:A56932

regarded as wholly impracticable.[1] Colonel Hitt in his *Manual for the Solution of Military Ciphers,* published in 1916, stated:

> The necessity for exact expression of ideas practically excludes the use of cod. for military work, although it is possible that a special tactical code might be useful for preparation of tactical orders.

Also, in an official British Army *Manual of Cryptography* prepared in 1914 is found the following statement:

> Codes will first be considered, but as they do not fulfill the conditions required of a means of secret communication in the field, they need not be dealt with here at length.

In the 1935 edition of this text the foregoing quotations were immediately succeeded by the following comment:

> It need only be pointed out in this connection that today code methods predominate in the secret communication systems of the military, naval, and diplomatic services of practically all the large nations of the world. Nevertheless, it is likely that within the next decade or two the pendulum may once more swing over to the other position and cipher methods may again come to the fore, especially if mechanical and electrical cipher machines are perfected so that their operation becomes practicable for general use. It is for this reason, if for no other, that the cryptographer who desires to keep abreast of progress must devote considerable attention to the more complicated cipher methods of the past and present time, for with the introduction of mechanical and electrical devices the complexities and difficulties of these hand-operated methods may be eliminated.

In preparing the revision of this text in 1943, the author found it necessary to say that the forecast he made in 1935 in regard to the rebirth of cipher methods had been fully justified by the present trend, which is in a direction away from code and toward cipher methods, because of important advances made in the field of mechanical and electrical cryptographic mechanisms.

b. Modern electrical communication methods and instrumentalities are finding an increasing need for applications of cryptographic theory and practice to their efficient operation. For example, in very recent years there has developed a distinct need for secure methods and means for distorting voice communications by telephone or radiophone, and for distorting facsimile transmissions by wire or radiotelegraphy. Teleprinter services permitting direct cryptographic intercommunication by machines operated from a typewriter keyboard make it desirable to have means whereby, although the keyboard is operated to correspond to plaintext characters, the latter are instantaneously and automatically enciphered in transmission and the received signals are instantaneously and automatically deciphered upon reception at the receiving end. Thus the printing mechanism at the receiving station records the original

[1] See, in this connection, Friedman, William F., *American Army Field Codes in the American Expeditionary Forces During the First World War,* Signal Security Service Publication, OCSigO, War Department, Washington, 1942.

REF ID:A56932

plain-text characters set up on the keyboard at the sending station but interception of the signals passing over the line or by radio would yield only cipher text.

c. It is difficult to foresee the specific cryptographic methods which might some day be useful in connection with developments of the foregoing nature. Progress in the electrical and electronic fields exercises an important effect upon developments in the cryptographic field. Methods which today appear to yield a high degree of cryptographic security but which are impractical for hand operation a few years from now, may be readily mechanized and become highly practical. On the other hand, methods which today do provide a high degree of security may, a few years from now, become obsolete because high-speed electrical analytical machines have been devised for their rapid solution. Consequently, if among the many and more or less complex methods set forth herein certain ones appear to fall outside the realm of what is today considered practicable, it should be remembered that the purpose in describing them is to present various basic cryptographic principles, and not to set forth methods that may with a high degree of probability be encountered in military cryptography in the immediate future.

Section II. TERMINOLOGY

3. Basic Definitions

In a study of military cryptography as employed in the U. S. Army, the following definitions will be useful:

a. SIGNAL COMMUNICATIONS. Any means of transmitting messages in plain or encrypted text other than by direct conversation or mail. A commander uses signal communications to receive reports of hostile dispositions and activities, to receive reports of the progress and needs of subordinate and neighboring friendly units, to send orders to subordinate units, to receive orders from superior units, and to send to higher and adjacent units information necessary for the coordinated action of the whole command.

b. AGENCY OF SIGNAL COMMUNICATION. The organization, teams, and personnel necessary to perform operational duties pertaining to signal communications.

c. MESSAGE. Used in its broadest sense in Department of the Army and other official publications, the term "message" includes all instructions, reports, orders, documents, photographs, maps, or other information, transmitted by means of signal communication. In this manual, however, the term "message" implies instructions, reports, orders, and similar communications usually transmitted by electrical means.

d. MEANS OF SIGNAL COMMUNICATION. A medium (including equipment) used by an agency for transmitting messages. There are two

REF ID:A56932

dozen or more different means; the most important, so far as this manua is concerned, are—

(1) *Wire:*
Telephone.
Telegraph.
Teletypewriter.
Facsimile (picture or photo transmission).

(2) *Radio:*
Radiotelephone.
Radiotelegraph.
Radio teletypewriter.
Radio facsimile.

e. WRITER. The person who actually prepares and signs the message blank. The writer may be the originator or his officially designated representative.

f. ORIGINATOR. The authority who orders the message written and sent. The commander may delegate this authority to one or more subordinates. Officers assigned as members of a unit's general staff are assumed to have been so designated.

g. TIME OF ORIGIN. The time shown on a message by the writer to indicate the hour and minute when he completed its writing.

h. ADDRESSEE. The authority (organization, office, or person) to whom a message is directed by the originator.

i. MESSAGE CENTER. That signal communication agency of a headquarters, or echelon thereof, which is charged with the receipt, routing and delivery of all official messages except: those which are transmitted directly from the originator to the addressee by means of a personal agent, or telephone or teletypewriter provided for his personal use; mail handled by military or civil postal services, and purely local messages.

j. COMMUNICATIONS CENTER. One or more agencies of signal communication equipped to receive, route, and transmit official messages. A communications center may be established at a point fixed or mobile.

4. Cryptology and Secret Communication

a. Secrecy of intercommunication in military operations is of the utmost importance. Need for it has been recognized from the earliest days of organized warfare. That branch of knowledge which treats the production, use and solution of the means and methods of secret[2] communications is called *cryptology.*

[2] Throughout this manual the term "secret" will be used in its ordinary sense as given in the dictionary. Whenever the designation is used in the more restricted sense of the security classification as defined in AR 380–5, it will be so indicated. There are in current use the classifications, *Restricted, Confidential, Secret,* and *Top Secret,* listed in ascending order of degree.

REF ID:A56932

b. Intercommunication may be conducted by any means susceptible of ultimate interpretation by one of the five senses, but those most commonly used are visual or auditory. Aside from the use of simple visual and auditory signals for intercommunication over relatively short distances, the usual method of intercommunication involves, at one stage or another, the act of *writing, speaking* over a telephone, or of *drawing* or *taking a picture.*

c. To preserve secrecy of intercommunication by telephone, there are means and methods of disguising the electrical currents in telephony so that the messages or conversations can be understood only by persons provided with the proper equipment. The same thing is true of secrecy in the electrical transmission of pictures, drawings, maps, etc. However, this manual is concerned only with secrecy of intercommunication by means of messages conveying in written words the thoughts, orders, reports, etc., of the originator to the addressee.

d. Writing may be either *visible* or *invisible.* In the former, the characters are inscribed with ordinary writing materials and can be seen with the naked eye; in the latter, the characters are inscribed by means or methods which make the writing invisible to the naked eye. Invisible writing is done with certain chemicals called *invisible, sympathetic,* or *secret inks* which have the property of either being initially invisible to the naked eye or becoming so after a short time. In order to make writing done with secret inks visible, special processes must usually be applied. There are also methods of producing writings which is invisible because the characters are of microscopic size. These methods usually require either special photographic apparatus or very delicate mechanical instruments called micropantographs, by means of which ordinary writing may be copied in extremely reduced size. Magnifying lenses must be used to make such writing visible to the naked eye.

e. Invisible writing and visible writing prepared in a form unintelligible in the language in which it is written, constitute *secret writing.* Both of these forms of secret writing have their uses in military communications, but this manual deals only with visible secret writing.

5. Plain Text and Encrypted Text

a. A visible message which conveys an intelligible meaning in the language in which it is written, with no hidden meaning, is said to be in *plain text.* A message in plain text is called a *plain-text message,* a *clear-text message,* or a *message in clear.*

b. A visible message which conveys no intelligible meaning in any language is said to be in *encrypted text.* Such a message is termed a *cryptogram.*

c. A visible message may convey an intelligible meaning which may not be the real meaning intended. To quote a simple example of a mes-

REF ID:A56932

sage containing a secret or hidden meaning, prepared with the intention of escaping suppression by censors in war time, the sentence "Son born today" may mean "Three transports left today." Messages of this type are in encrypted text and are said to be in *open code.* Although occasionally useful in espionage and counter-espionage, secret communication systems of this sort are impractical for field military use, and will not be dealt with further in this manual.

d. The term "correspondents" is used in this manual to designate persons who exchange messages with each other. Between the originator and the addressee there may be persons who actually write and handle the messages, who convert the plain texts into cryptograms, or who reconvert the cryptograms into plain texts. The originator and the addressee may also do this work but in the U. S. Army such work is usually done by special personnel who act as agents of the correspondents.

e. The term "enemy" is used in this manual to designate all persons who obtain messages or copies of messages not intended for them.

6. Cryptography, Cryptographing, and Decryptographing

a. Cryptography is that branch of cryptology which treats of various means and methods for rendering plain text unintelligible and reconverting unintelligible text into plain text or the application thereof.

b. To *cryptograph*[3] (*encrypt*) is to convert a plain-text message into a cryptogram by following certain rules agreed upon in advance by correspondents, or furnished them or their agents by higher authority. The process of *cryptographing* a message produces a *cryptogram.*

c. To *decryptograph* (*decrypt*) is to reconvert a cryptogram into the equivalent plain-text message *by a direct reversal of the cryptographing process;* that is, by applying to the cryptogram the key used in cryptographing the plain text.

d. A person skilled in the art of cryptographing and decryptographing, or one who has a part in making a cryptographic system is called a *cryptographer;* a clerk who cryptographs and decryptographs, or who assists in such work, is called a cryptographic clerk.

7. Codes, Ciphers, and Enciphered Code

a. Cryptographing and decryptographing are accomplished by means collectively designated as *codes* and *ciphers.* Such means are used for either or both of two purposes: (1) secrecy, and (2) economy or brevity. Secrecy usually is far more important in military cryptography than economy or brevity. In ciphers or *cipher systems* cryptograms are produced by applying the cryptographic treatment to *individual letters* of the plain-text messages, whereas in codes or *code systems* cryptograms are produced by applying the cryptographic treatment to entire words,

[3] Compare the terms *"cryptography," "cryptogram,"* and *"cryptograph"* with the terms *"telegraphy," "telegram,"* and *"telegraph."*

REF ID:A56932

phrases, and sentences of the plain-text messages. The specialized meanings of the terms *code* and *cipher* are explained in detail later.

b. A cryptogram produced by means of a cipher system is said to be *in cipher* and is called a *cipher message,* or sometimes simply a *cipher.* Such act or operation of cryptographing is called *enciphering,* and the enciphered version of the plain text, as well as the act or process itself, is often referred to as the *encipherment.* The cryptographic clerk who performs the process serves as an *encipherer.* The corresponding terms applicable to the decryptographing of cipher messages are *deciphering, decipherment,* and *decipherer.* A clerk who serves both as an encipherer and decipherer of messages is called a *cipher clerk.*

c. A *cipher device* is an apparatus or a simple mechanism for literal encipherment and decipherment, usually manually powered; a *cipher machine* is an apparatus or complex mechanism for literal encipherment and decipherment, usually requiring an external power source.

d. A cryptogram produced by means of a code system is said to be *in code* and is called a *code message,* or sometimes simply a *code.* The text of the cryptogram is referred to as *code text.* This act or operation of cryptographing is called *encoding,* and the encoded version of the plain text, as well as the act or process itself is referred to as the *encodement.* The clerk who performs the process serves as an *encoder.* The corresponding terms applicable to the decryptographing of code messages are *decoding, decodement,* and *decoder.* A cryptographic clerk who serves both as an encoder and decoder of messages is called a *code clerk.*

e. Sometimes, for special purposes, the code text of a cryptogram undergoes a further step in concealment involving an enciphering process, thus producing what is called a cryptogram in *enciphered code,* or an *enciphered-code message. Encoded cipher,* the cipher text of a cryptogram which subsequently undergoes encodement, is also possible but rare.

f. In U. S. Army tables of organization and other publications, cipher clerks and code clerks are cryptographic technicians. They are specifically trained to encipher, decipher, encode, and decode messages, using authorized means, equipment, and procedures.

8. General System and Specific Key

a. The total of all the basic, invariable rules followed in cryptographing a message according to a given method, together with all the agreements, conventions or private understandings drawn up between the correspondents or their authorized agents or furnished them by higher authority, constitute the *general cryptographic system.*

b. In the general cryptographic system usually a number, a group of letters selected at random, a word, a phrase, or a sentence, is used as a key. The element selected governs the manner in which a cipher device or a cipher machine is prepared for the encipherment or decipherment

REF ID:A56932

of a specific message, or it controls the steps followed in cryptographing a specific message. This element—usually of a variable nature and changeable at the will of the correspondents, or prearranged for them or for their agents by higher authority—is the *specific key*. The specific key may also involve the use of a set of specially prepared tables, a special document, or even a book.

c. Hereafter, the general cryptographic system will be referred to as the *system,* and the specific key, as the *key.*

9. Cryptanalytics and Cryptanalysis

a. In theory, any cryptographic system except one can be broken down if enough time and skill are devoted to it, and if the volume of traffic is large enough. This can be done even if the general cryptographic system and the specific key are unknown at the start. The exception is the "one time" system in which the key is used only once and in itself must have no systematic construction, derivation, or meaning. In military operations theoretical rules must usually give way to practical considerations. How the theoretical rule in this case is affected by practical considerations will be taken up in subsequent portions of this manual.

b. That branch of cryptology which deals with the principles, methods, and means employed in the solution or *analysis* of cryptograms is called *cryptanalytics.*

c. The steps and operations performed in applying the principles of cryptanalytics constitute *cryptanalysis.* To cryptanalyze a cryptogram is to *solve* it by cryptanalysis.

d. A person skilled in the art of cryptanalysis is called a *cryptanalyst,* and a clerk who assists in such works is called a *cryptanalytic technician.*

Section III. TWO CLASSES OF CRYPTOGRAPHIC SYSTEMS

10. Transposition and Substitution

a. Technically there are only two distinct types of treatment which may be applied to plain text to convert it into secret text, yielding two different *classes* of cryptograms. In the first, called *transposition,* the *elements* or *units* of the plain text, whether one is dealing with individual letters or groups of letters, syllables, whole words, phrases and sentences, retain their original identities and merely undergo some change in their relative positions or sequences so that the message becomes unintelligible. In the second, called *substitution,* the elements of the plain text retain their original positions or sequences but are replaced by other elements with different values or meanings.

b. It is possible to cryptograph a message by a substitution method and then to apply a transposition method to the substitution text, or vice

REF ID:A56932

versa. Such combined transposition-substitution methods do not form a third category of methods. They are occasionally encountered in military cryptography, but the types of combinations that are sufficiently simple to be practicable for field use are very restricted.

11. Letter, Syllable, and Word Methods

Under each of the two principal classes of cryptograms as outlined in the preceding paragraph, a further classification can be made with respect to the nature of the *textual elements* or *units* with which the cryptographic process deals. These textual units are (1) individual letters, or groups of letters in regular sets, and (2) complete words. Methods which deal with the first type of units are called *letter methods,* including, when such is the case, *syllable methods;* those which deal with the second type of units are called *word methods.*

12. Cipher Systems and Code Systems

It is necessary to indicate that the classification into letter, syllable, and word methods is more or less arbitrary or artificial in nature, and is established for purpose of convenience only. No sharp line of demarcation can be drawn in every case, for occasionally a given system may combine methods of treating single letters, groups of letters, syllables, whole words, phrases and sentences. When in a single system the cryptographic treatment is applied to textual units of regular length, usually single letters or pairs, and is only exceptionally applied to textual units of irregular length, the system is called a *cipher system.* Likewise, when in a single system the cryptographic treatment is applied to textual units of irregular length, usually whole words, phrases, and sentences, and is only exceptionally applied to single letters, pairs, or groups of letters and syllables, the method is called a *code system* because it generally involves the use of a code book.

Section IV. SECURITY AND TIME ELEMENTS IN CRYPTOGRAPHIC SYSTEMS

13. Interception, Radio Direction Finding, and Radio Position Finding

a. Messages transmitted by electrical means can be heard and copied by persons who are not the correspondents or their authorized agents. Messages transmitted by radio can be manually copied or automatically recorded by suitably adjusted radio apparatus located within range of the transmitter. Some messages transmitted over wire lines can likewise be

REF ID:A56932

manually copied or automatically recorded by special apparatus suited for the purpose. Correspondents have no way of knowing whether or not radio transmissions are being copied by the enemy, since the unauthorized copying does not interfere in the slightest degree with signals being transmitted. Interception of wire traffic is much more difficult than of radio, mainly because the equipment must be located very near the wire line, or connected directly to it. The act of listening-in and copying or recording electrically-transmitted messages by persons other than the correspondents or their authorized agents is called *interception.* The purpose of interception is to obtain copies of messages transmitted and, by studying them, to obtain information. In time of war, it must be assumed that the enemy will intercept all messages transmitted by any signal communication agency susceptible of interception.

b. It is also possible to determine, with a fair degree of accuracy, the direction of a radio transmitter from a given location and, by establishing the direction from two or more locations, it is possible to determine the geographical location of the transmitter. The science which deals with the means and methods of determining the direction in which a radio transmitter lies is called *radio direction finding;* the method of determining the geographical location of a radio transmitter, by the use of two or more direction-finding installations, is called *radio position finding.*

c. Messages may be transmitted by signals with special apparatus which distort, disguise, or completely hide the signals themselves, so that the processes of interception and recording the signals are very difficult, and intercept personnel may not even be aware of the existence of such signals. All such methods of transmitting messages fall in the class designated in this manual as *systems of secret signaling.* Signaling by means of so-called "black light," that is, invisible or infra-red light waves, falls into this category. Methods of disguising or distorting voice or picture transmissions (par. 2*c*) require more or less highly-specialized apparatus for the interception of the signals and their interpretation or recording in recognizable form. As a rule, the signals of practically all systems of secret signaling can be intercepted and recorded in a form suitable to making the signals understood by one of the senses, usually visual or auditory. Ordinarily, this requires special apparatus but can sometimes be done without the specific apparatus used in forming or sending the signals, or the "key" used in their distortion, or disguise.

14. Traffic Analysis and Cryptanalysis

a. A great deal of information of military value can be obtained by studying signal communications without solving the crytographed messages constituting the traffic. The procedure and the methods used have yielded results of sufficient importance to warrant the application of a

REF ID:A56932

special term to this field of study; namely, *traffic analysis*[4], which is the study of signal communications and intercepted or monitored traffic for the purpose of gathering military information without recourse to cryptanalysis.

b. In general terms, traffic analysis is the careful inspection and study of signal communications for the purpose of penetrating camouflage superimposed upon the communication network for purposes of security. Specifically, traffic analysis reconstructs radio communication networks by: (1) noting volume, direction, and routing of messages; (2) correlating transmission frequencies and schedules used among and within the various networks; (3) determining directions in which transmitters lie, by means of radio direction finding; (4) locating transmitters geographically, by radio position finding; (5) developing the system of assigning and changing radio call signs; (6) studying all items that constitute "conversations" or "chat" exchanged among operators on radio channel.

c. From a correlation of general and specific information derived from these procedures, traffic analysis is able not only to ascertain the geographic location and disposition of troops and military units (technically called "order of battle") and important troop movements, but also to predict with a fair degree of reliability the areas and extent of immediately pending or future activities. Traffic analysis procedures are followed to obtain information of value concerning the enemy, and to determine what information concerning our own forces is made available to the enemy through our own signal communications.

d. These very important results are obtained without actually reading the texts of the intercepted messages; the solution and translation of messages are the functions of cryptanalysis and not traffic analysis. However, the cryptanalyst is frequently able to make good use of bits of information disclosed by traffic analysis such as faults noted in message routing and errors in cryptography causing messages to be duplicated or canceled. Cryptanalysis can provide important information for traffic analysis, since the solution of messages often yields data on impending changes in signal communication plans, operating frequencies and schedules, etc. It also yields data on specific channels, networks, or circuits which are most productive of intelligence, so that effective control and direction of intercept agencies for maximum results can be achieved.

e. In addition to (1) traffic analysis and (2) cryptanalysis as means of obtaining information relating to communications, further data may be obtained (3) by the use of secret agents for espionage, (4) by the capture and interrogation of prisoners, (5) by the capture of headquarters or command posts with records more or less intact, and (6) by treason or carelessness on the part of personnel who handle communications. Of

[4] Which may be abbreviated *tranalysis.*

REF ID:A56932

these six main sources, traffic analysis and cryptanalysis are the most valuable. The amount of vital information they furnish cannot be accurately estimated as it fluctuates with time, place, circumstances, equipment, and personnel. For most effective operation, the results of both cryptanalysis and traffic analysis can be fitted together to yield a unified picture of the communications scheme. Therefore, if all transmitting stations can be located quickly and if all communications can be intercepted and solved, extremely valuable information concerning strength, disposition of forces, and proposed moves will be continually available.

f. The facts set forth above are applicable to our own forces as well as the enemy's.

g. The process of intercepting and copying our own or friendly radio and wire transmissions for the purpose of detecting and correcting violations of regulations is called *monitoring;* it provides increased protection of our own signal communications.

15. Communication Intelligence and Communication Security

a. Communication intelligence is evaluated information concerning the enemy, derived principally from a study of his signal communications. The main components of communication intelligence are as follows:

(1) Interception of signals or messages and forwarding raw traffic to communication intelligence centers for study.

(2) Traffic analysis, including radio direction finding and radio position finding. (Evaluated information from this source is often called *traffic intelligence.*)

(3) Cryptanalysis or solution (and translation, when necessary) of the texts of the messages.

(4) Evaluation of data, that is, analysis of results obtained from the preceding steps and their correlation, collation, and comparison with results obtained from other sources of information.

b. Communication security is the protection resulting from all measures designed to deny to unauthorized persons information of value which may be derived from communications. The main components of communication are as follows:

(1) *Physical security,* that component of communication security which results from all measures necessary to safeguard classified communication equipment, and material from access thereto by unauthorized persons.

(2) *Cryptosecurity,* that component of communication security which results from the provision of technically sound *cryptosystems*[5] and their proper use.

[5] *Cryptosystems* may be categorized as literal and nonliteral. This manual is concerned solely with *literal* or *cryptographic* systems.

REF ID:A56932

(3) *Transmission security,* that component of communication security which results from all measures designed to protect transmissions from interception and traffic analysis.

c. Further details on the subject of communication security will be found in JANAP 122(A) Joint Communications Instructions.

16. Time Needed for Cryptanalysis and its Dependent Factors

a. In military operations time is a vital element. The influence or effect that analysis of military cryptograms may have on the tactical situation depends on various time factors.

b. Of these factors, the following are the most important:

(1) The length of time necessary to transmit intercepted enemy cryptograms to solving headquarters. This factor is negligible only when signal communication agencies are properly and specifically organized to perform this function.

(2) The length of time required to organize raw materials, to make traffic analysis studies and to solve the cryptograms, and the time required to make copies, tabulate, and record data.

(3) The nature of information disclosed by traffic analysis studies and solved cryptograms; whether it is of immediate or operational importance in impending action, or whether it is of historical interest only in connection with past action.

(4) The length of time necessary to transmit information to the organization or bureau responsible for evaluating the information. Only after information has been evaluated does it become *military intelligence.*

(5) The length of time necessary to transmit resulting military intelligence to the agency or agencies responsible for tactical operations, and the length of time necessary for the agency to prepare orders for the action determined by the intelligence and to transmit them to the combat units concerned. The last sentence under (1) above applies here also.

c. Of the factors mentioned in *b* above, the only one of direct interest in this manual is the length of time required to solve the cryptograms. This is subject to great variation, dependent upon other factors, of which the following are the most important:

(1) *The degree of cryptographic security* in the system. The degree of security depends upon the technical soundness of the system itself. Technical soundness, in turn, determines the resistance to analysis which the system offers. Cryptographic systems vary widely in technical soundness, but this manual does not attempt to demonstrate such variation.

REF ID:A56932

(2) The adequacy and technical soundness of regulations drawn up by designers of the cryptographic system for the guidance of cryptographic technicians who are its actual users.

(3) The extent to which cryptographic technicians follow these regulations and procedures. Security of a good cryptographic system can be almost completely destroyed by a few cryptographic technicians who fail to observe the regulations, are careless in their observance, in sheer ignorance commit serious violations of cryptographic security, *or adopt bad technical habits.* As a result, these technicians jeopardize not only their own lives but the lives of thousands of their comrades.

(4) The volume of cryptographic text available for study. As a rule, the greater the volume of text, the more easily and speedily it can be solved. A single cryptogram in a given system may present an almost hopeless task for the cryptanalyst, but if many cryptograms of the same system or in the same or closely related specific keys are available for study, the solution may be reached in a very short time.

(5) The number, skill, and efficiency of organization and cooperation of signal intelligence units assigned to the work. Cryptanalytic headquarters are organized in units of ascending size, ranging from a few persons in the forward echelons to many persons in the rear echelons. Such organization avoids duplication of effort and, especially in forward areas where spot intelligence is most useful, makes possible the quick interpretation of cryptograms in already solved systems. In all these units, proper organization of highly skilled workers is essential for efficient operation.

(6) The amount and character of information and intelligence available to the cryptanalytic headquarters. Isolated cryptograms exchanged between a restricted, small group of correspondents, about whom and whose business no information is available, may resist the efforts of even a highly organized, skilled cryptanalytic office indefinitely. If, however, a certain amount of such information is obtained, the situation may be entirely changed. In military operations usually a great deal of collateral information is available, from sources indicated in paragraph 14*e*. As a rule, a fair amount of more or less definite information concerning specific cryptograms is at hand, such as proper names of persons and places, and events in the immediate past or future. Although the exchange of information between intelligence and cryptanalytic staffs is very important, the collection of information derived from an intensive study of already solved traffic is equally as important because it yields extremely

REF ID:A56932

valuable *cryptanalytic intelligence* which greatly facilitates the solution of new cryptograms from the same sources.

17. Degree of Crytographic Security Required of a System for Military Use

The ideal cryptographic system for military purposes would be a *single, all-purpose* system which would be practicable for use not only by the largest fixed headquarters but also by the smallest troop unit in the combat area, and which would also present such a great degree of cryptographic security that, no matter how much traffic became available, all in the same key, the cryptograms composing this traffic would resist solution indefinitely. Such an ideal system however, is beyond the realm of possibility so far as present methods of cryptographic communication are concerned; in fact, a multiplicity of systems must be employed, each more or less specifically designed for a particular purpose. Of each such system, *the best that can be expected is that the degree of security be great enough to delay solution by the enemy for such a length of time that when the solution is finally reached the information thus obtained has lost all its "short term," immediate, or operational value, and much of its "long term," research, or historical value.*

18. Fundamental Practical Requirements of a Cryptographic System for Military Use

a. Military cryptograms must meet certain fundamental requirements of a practical nature because of definite limiting conditions in present military signal communication means and methods.

b. These requirements are (1) reliability, (2) security, (3) rapidity, (4) flexibility, and (5) economy. Their relative importance is in the order named.

c. Reliability is of first importance. Reliability, as applied to a cryptographic system or device, means that the cryptograms produced by the sending or originating office will be decryptographed promptly, accurately, and without ambiguity by the receiving office; that the cryptographic system, whether a book, machine, or device, will be on hand and in good working order, available for instant use; and that when used it can be expected to be operative as long as needed. Simplicity is implied in reliability; usually, the more simple the system, the more reliable it is. Security is the protection afforded by a sound cryptographic system; rapidity, the speed with which messages can be cryptographed and decryptographed, usually expressed in words or 5-letter groups per minute. The conflicting requirements of *security* and *rapidity* vary according to circumstances. Signal communication personnel must be governed by general principles, subject to existing circumstances, rather than by rigid

REF ID:A56932

regulations. Maximum security at all times should be the goal, but in messages exchanged among the higher headquarters some speed may be sacrificed to meet greater security requirements, while in messages exchanged among the lower headquarters security must often give way to greater speed requirements. For this reason various cryptographic systems must be available to meet varying types of situations. As to flexibility, a cryptographic system specifically adapted for a particular usage cannot serve as an all-purpose system. A codebook designed for front-line use can hardly serve the needs of a high headquarters in the rear; nor can a cryptographic system designed for use by a high headquarters serve the needs of a small combat unit. As to economy, the simpler the operations involved, the shorter will be the texts produced, the amount of time required to produce the cryptographic material, use it, and transmit the messages; and the greater will be the economy.

d. Specific requirements which should be met by a cryptographic system for general military use are set forth below.

(1) Cryptograms must be in a form suitable for transmission by standard telegraphic equipment and methods. This requirement generally eliminates all systems except those which produce cryptograms composed of characters readily transmitted by a telegraphic system employing either the Morse or the teleprinter alphabet. Cryptographic systems using Arabic numerals are not so desirable as those using letters because the Morse signals for numbers are longer, except when "cut" numbers are used, and are more difficult for the average American telegraph or radio operator to handle. Systems which produce cryptograms composed of mixtures of letters and figures, or of letters, figures, and punctuation signs, and which must be transmitted by Morse telegraphy are unsuited for practical usage. However, where such intermixtures are produced automatically by the cryptographic mechanism and are transmitted, received, and deciphered automatically, as certain teleprinter enciphering systems, their use is permissible. In order to be suitable for economical Morse telegraphic transmission, the cryptographic text must be capable of being arranged in regular sets of characters for these reasons: first, it promotes accuracy in telegraphic transmission (since an operator knows he must receive a definite number of characters in each group, no more and no less); and secondly, cryptanalysis is usually made more difficult when the length of the words, phrases, and sentences of the plain text is not apparent. The usual grouping is in sets of five characters, although occasionally other groupings may be made in special circumstances. Such grouping is not necessary in teleprinter encipherment systems.

REF ID: A56932

(2) Regular channels of signal communication can carry only a limited volume of traffic. Their most efficient operation demands that the smallest number of characters actually necessary to convey a given message be transmitted. Therefore, the cryptographic text should be no longer than its equivalent clear text. In an exceptional case, the cryptographic text may be longer than the equivalent clear text, but a system in which the cryptographic text is twice the length of the equivalent clear text is useful only if it is of outstanding merit and suitable for certain restricted or special use. No system in which the cryptographic text is more than twice the length of the equivalent clear text is practicable for military usage. Most of the cryptographic systems in current use produce cryptograms which correspond in length with that of the original plain-text message or are somewhat shorter.

(3) General requirements of reliability and speed are that the operations of cryptographing and decryptographing be relatively simple and rapid. For use in the combat zone, operations must be capable of being performed under difficult field conditions and must not require the remembering and application of a long series of steps or rules. They must be such as to reduce the mental strain on the operator to a minimum. Complex processes requiring several distinct steps are not suited to use in the combat zone, but occasionally systems involving only two steps, if each step is simple and rapid, may be practicable for military usage.

(4) Cipher devices or machines for field use must be light in weight, rugged in construction, and simple in operations, requiring the services of only one operator. Requirements to be met by high-speed cipher machines are too complex to be described in this manual.

(5) The system must be such that errors, which invariably occur in cryptographic communications, can be corrected easily and rapidly by cryptographic technicians. A system is impractical if frequently it is necessary to call for a repetition of the whole transmission, or for a rechecking of the original cryptographing.

e. Only a few of the systems which fulfill at least several of the foregoing practical requirements are included in this manual.

REF ID:A56932

CHAPTER 2
ELEMENTARY TRANSPOSITION SYSTEMS

Section 1. SIMPLE MONOLITERAL TRANSPOSITION METHODS

19. Transposition Ciphers in General

Transposition ciphers are like "jig-saw puzzles" in that all the pieces of which the whole original is composed are present but are merely disarranged. The pieces into which the picture forming the basis of a jig-saw puzzle may be divided are irregular in size and shape, but the pieces into which the plain text forming the basis of a transposition cipher may be divided must be much more regular, for the sake of practicability. They must be either single letters or pairs of letters, or sets of letters in regular groupings, or, in an exceptional case, whole words. Most transposition methods however, deal with individual letters and are therefore termed "monoliteral methods." The other methods are termed "polyliteral methods."

20. Geometric Designs

a. Practically all monoliteral or polyliteral transposition ciphers involve the use of a design or geometric figure, such as a square, rectangle, triangle, trapezoid, etc., in which the letters of the plain text are first *inscribed* or written according to a previously agreed-upon direction of writing and then *transcribed* or rewritten according to another and different, previously agreed-upon direction to form the text of the cryptogram. In nearly all cases the specific key consists in (1) using designs of a specific nature and dimensions, and (2) varying the direction or manner of inscription or transcription, or both.

b. In working with transposition ciphers or, for that matter, most types of ciphers, cross-section paper will be found very convenient. Cross-section paper with ¼-inch squares is most suitable. For brevity in reference, the individual small squares of such cross-section paper will hereafter be called *cells.*

21. Route Transpositions

a. Suppose the correspondents agree to use the method of monoliteral transposition known as *route transposition.* The message is inscribed

REF ID:A56932

within a rectangle in the usual manner of writing, that is, from left to right and in consecutive lines from top to bottom. If one or more cells are vacant at the end, *nulls* or *dummy* letters—letters having no significance—are inserted as "fillers" to complete the rectangle. Then, to form the cipher text, the letters in the design are taken out of the design and rewritten or transcribed by following or tracing one of many different routes. It is possible for each route to have a different starting point, and normally it is one of the four corners of the rectangle. A few typical routes are illustrated in figure 1 where, for the sake of ease in following the route, the plain-text message is assumed to be merely the sequence of letters A B C ... X.

Figure 1—Continued.

REF ID:A56932

b. It is apparent that instead of following the normal direction of writing, that is, from left to right and from the top downwards, the letters of the plain text may be inscribed according to any one of the routes agreed upon, and then transcribed to form the cipher text by taking the letters from the rectangle in the normal manner, that is, in this case from left to right, and from the top downwards, or *by following any other route of transposition.*

22. Example of Encipherment and Decipherment by Monoliteral Route Transposition

a. Now take a special example of encipherment by monoliteral route transposition. Use the message ATTACK HAS BEEN POSTPONED UNTIL TOMORROW TWO AM, and employ a relatively complicated method. Suppose that the general system agreed upon is the one being described, and that the specific key consists of the following elements:

(1) Using a completely filled rectangle of seven columns;
(2) Inscribing the letters of the plain text within the rectangle by following route (F) (3) of figure 1;
(3) Transcribing the thus inscribed letters (to form the cipher text) by following route (E) (6) of figure 1.

Since the message contains a total of 40 letters, and it has been agreed to use a completely filled rectangle of seven columns, it is necessary to add two nulls to make the total number of letters a multiple of seven. A rectangle of seven columns of cells and six lines of cells is therefore prepared. The design is then filled in as shown in figure 2.

b. To decryptograph such a cryptogram the process is merely reversed. First, the total number of letters in the cipher text must be found. Since

S	L	T	T	W	L	T
O	T	I	O	W	O	M
H	P	P	T	M	O	A
K	A	N	O	N	O	R
T	C	S	E	N	U	R
A	T	A	B	E	E	D

Cryptogram:

TMLAO WROWT ROMOT DUNTI LENOP
TSEEN POBSA HACKT TA

Figure 2

REF ID:A56932

it is 42, and since a completely filled rectangle of seven columns has been agreed upon, a design consisting of seven columns and six rows is outlined on cross-section paper. The cipher text is then inscribed according to route (E) (6) of figure 1, and after this has been completed the plaintext letters are read according to route (F) (3), figure 1. It is apparent that it is necessary to remember a relatively long series of rules, and even when the cryptographing has been accomplished correctly the degree of security is very low. Note how obviously the whole word UNTIL manifests itself in the cipher text. Parts of other words can also be seen. The degree of security remains very low despite the variability afforded by the dimensions of the rectangle, the method of inscription and transcription and their starting points.

23. Use of Nulls in Transposition

a. It will be noted that the two nulls selected as fillers to complete the rectangle in the preceding example were the letters L and T. These were chosen rather than such letters as J, K, Q, X, or Z, for a reason which is important to note. Since transposition ciphers of this type involve merely a rearrangement of the letters, without any change whatever in their identities, it follows that the natural or normal frequencies of letters of plain text remain unchanged. Now, the letters of every alphabetic language have characteristic frequencies, as a result of which certain clues are afforded in cryptanalysis. The presence, in transposition ciphers, of letters of very low frequency (in English), such as J, K, Q, X, or Z, is very unusual and therefore if these are employed merely as fillers they may afford clues as to the real number of letters in the plain text, the starting or finishing points of the real text, etc. For this reason it is best to insert as fillers in transposition ciphers letters of medium or high frequency, such as E, T, R, I, N, O, A, S, D, L, or C, for these will not afford any clues to solution. Nulls, when employed for the purpose of making cryptanalysis more difficult, may also be inserted in specific positions as prearranged, or they may be inserted at random if the system permits. This is true of other cryptographic systems, but as a general rule the use of nulls, especially in cipher systems, is to be discouraged. Very often they add little if any security, and thus merely increase the length of the cryptographic text without any compensating advantages.

b. Whenever it is necessary to add nulls in order to complete a transposition message in any respect, or for any reason whatsoever, they must be added *before* the transposition process is applied and not afterward; otherwise it will be difficult or even impossible for the decryptographing clerk to read the message. This is especially true when the service regulations require that the final group in a cryptogram be a complete group, containing exactly as many letters as all other groups in the message.

REF ID:A56932

24. Special Cases of Route Transposition

a. The oldest and simplest transposition method known, that called reversed writing, is a special case of one of the routes shown in figure 1. Here the text is written in the opposite direction from the normal; for example, BRIDGE DESTROYED is written EGDIRB DEYORTSED. The variability of the scheme, that is, the *specific key,* consists of the fact that the reversal may be applied to groups of fixed length, to whole words, to sentences, or to the whole text. The security of simple reversed writing may be somewhat increased by disguising the original word lengths, by which is meant a destruction of the normal, or natural word limits by combining a part of one word with a part of the next to form either *false words* or groups of regular length.

b. Some examples of reversed writing follow. Let the message be: BRIDGE DESTROYED AT ELEVEN PM.

(1) Reversing only the words and retaining original word lengths:
Cipher: **EGDIRB DEYORTSED TA NEVELE MP**

(2) Reversing only the words and regrouping into false word lengths:
Cipher: **EG DIRB DEYORT SEDTA NEVE LEMP**

(3) Reversing the whole text and regrouping into fives:
Cipher: **MPNEV ELETA DEYOR TSEDE GDIRB**

(4) Reversing the whole text, regrouping into fives, and inserting a null in every fifth position:
Cipher: **MPNER VELEO TADEB YORTH SEDEA GDIRB**

c. A second very simple type of transposition, that known as *vertical writing,* is a special case of another of the routes shown in figure 1.

The message BRIDGE DESTROYED is written in two vertical columns, and the cipher text is taken from the horizontal pairs thus formed. The message becomes:

BSRTI RDOGY EEDDE

BS
RT
IR
DO
GY
EE
DD
E

Figure 3.

When the plain text is inscribed in pairs of letters in vertical writing and then the cipher text is taken by transcribing the columns, a slightly different result is obtained. Using the plain text message BRIDGE DESTROYED, the cipher becomes:

BIGDS RYDRD EETOE

BR
ID
GE
DE
ST
RO
YE
D

Figure 4.

REF ID:A56932

This type of transposition is sometimes called the *rail-fence* cipher because it can be produced by writing the message in the following form:

B I G D S R Y D
R D E E T O E

which yields the same cipher result as before.

25. Remarks on Monoliteral Route Transposition

Reversed writing and vertical writing of the types indicated yield extremely simple cryptograms. In practice they are sometimes used in connection with other more or less simple cryptographing methods to increase their security. The cryptographic security of the other methods thus far indicated is also very low, despite the apparently large degree of variability they afford. The reason is that the route to be followed in the inscription or transcription process is definitely fixed under each type of route. In other types of transposition soon to be discussed, a much wider latitude for variation in the route is afforded by the use of key words to control or to guide these processes. Geometric designs are also used in these types of transposition, and key words determine the dimensions of the design, or else, if only one key word is used, it determines one dimension, the other being determined by the length of the text. Examples given in their proper place will serve to illustrate the processes.

26. Key Words and Numerical Keys

a. It is often necessary, in performing certain cryptographic operations, to employ a *numerical key,* which may consist of a relatively long sequence of numbers difficult or impossible for the average cipher clerk to memorize. To avoid making it necessary that such sequences of numbers be carried on the person in written form, a dangerous procedure, cryptographers have devised very simple methods of deriving such sequences from words, phrases, or sentences, which can usually be remembered much more easily than can unintelligible, relatively long sequences of numbers. One of the simplest methods is to assign numerical values to the letters of the key in accordance with their relative positions in the ordinary alphabet. Such a key is called a *derived numerical key.* This method of assigning the numbers is very flexible and varies with different uses to which numerical keys are put. For purposes of transposition, the method shown below is very satisfactory.

b. Let the prearranged key word be the word CARBUNCLE. Since the word contains the letter A, which comes first in the alphabet, the number 1 is written under this letter in the key word. Thus:

C A R B U N C L E
1

REF ID:A56932

The next letter of the normal alphabet that occurs in the key word is B, which is assigned the number 2. The letter C, which occurs twice in the key word, is assigned the number 3 for its first occurrence, the number 4 for its second occurrence, and so on. The final result is:

Basic key word: C-A-R-B-U-N-C-L-E
Derived numerical key: 3-1-8-2-9-7-4-6-5

c. The method may, of course, be applied to phrases or to sentences, so that a very long numerical key, impossible ordinarily to remember, may be so derived at will from an easily remembered *key text.*

d. It is advisable to make note of a few points valuable in connection with the choice of key text:

(1) It should be such as can be easily remembered. Often a key composed of two or more short words is better than one consisting of a single long word. Thus, the whole sentence WHEN DO WE EAT would be better than the single word EXTRAORDINARY.

(2) It should consist of one or more *simple,* familiar words admitting of but *one* spelling. A word such as REINFORCEMENT is inadvisable because the spelling REENFORCEMENT is also admissible. It goes almost without saying the use of words suitable for "spelling bees," even though they may be familiar, everyday words as DEFINITELY, SEPARATELY, REPETITION, etc., is likewise inadvisable.

(3) It should contain as many different letters as possible, in no systematic sequence. Words with several repeated letters, such as ELEMENT, BANANA, MISSISSIPPI, etc., form poor key words.

(4) It should present no associations with the special situation in which it is used, so as not to be easily guessed by the enemy. For example, to use personal or geographic names associated with a region in the theater of operations is bad practice. The key word GETTYSBURG employed in a cryptogram originating in the vicinity of Gettysburg would be bad practice. Or to use for this purpose words of common military usage, such as BATTALION, REGIMENT, ARTILLERY, SIGNAL CORPS, MACHINE GUN, etc., is likewise bad practice.

e. It is convenient to designate key text in letters as a *literal key.* As noted, a literal key may consist of a single letter, a single word, a phrase, a sentence, whole paragraph, or even a book. The method of deriving a numerical key from a literal key given in *b* above is only one of a number of methods, but it is the most commonly employed. It is also subject to variation in detail. But, so far as the cryptanalyst is concerned, just how the numerical key is derived from a specific literal key is usually of interest to him only if this knowledge will assist in subsequent solutions

REF ID:A56932

of cryptograms prepared according to the same basic system. Often the cryptanalyst is wholly unconcerned as to whether a literal or a numerical key has been used in connection with cryptographing of the messages, and he may frequently be unaware of the fact that a literal key has been used as the basis for deriving a numerical key.

Section II. COLUMNAR TRANSPOSITION METHODS

27. Columnar Transposition with Completely Filled Rectangles

a. One of the most common types of transposition involving the use of a key word or a derived numerical key is that known as *keyed* or *variable-key columnar transposition.* In this type the letters are usually written in a geometric design, most often a rectangle, by inscribing them in the ordinary manner, that is, in horizontal lines from left to right and from the top downwards, and then the letters are transcribed by "reading" the columns in the sequence determined by the numerical key. If the text does not contain a sufficient number of letters to fill the last line completely, as many nulls as are necessary to do so are added at the end. Figure 5 is an example of cryptographing by this method.

Key word: L - I - B - E - R - T - Y
Numerical key: 4 - 3 - 1 - 2 - 5 - 6 - 7

R	E	P	O	R	T	L
O	C	A	T	I	O	N
O	F	S	E	C	O	N
D	B	A	T	T	A	L
I	O	N	C	O	M	M
A	N	D	P	O	S	T
T	O	D	A	Y	D	N

Note. The letters D and N in the final two cells are nulls, inserted to complete the rectangle.

Cryptogram:

PASAN DDOTE TCPAE CFBON OROOD IATRI CTOOY
TOOAM SDLNN LMTN

Figure 5.

REF ID:A56932

b. To decryptograph such a cryptogram, a rectangle with the proper number of cells, determined by the length of the message and the length of the key, must first be prepared. In the foregoing example, since the cipher text consists of 49 letters and the key consists of 7 letters or num-

Cryptogram:

(c)

*The letters D and N are recognized as nulls.

Figure 6.

REF ID:A56932

bers, the rectangle shown in (a) of figure 6 is prepared and then the columns (of cells) are filled in numerical order. An early stage in the decryptographing is represented in (b) of figure 6. It is only after the process has been finished that the complete message reappears, as shown in (c) of figure 6.

c. The method indicated above may vary considerably by changing (1) the key word, (2) the route followed in inscribing the letters of the plain text, and (3) the route followed in transcribing them to form the cipher text. A change in key daily, or oftener, is possible; or, by drawing up a whole list of daily keys for a given period, automatic change in key can be provided for without indicating in the cryptograms the applicable key. It is also possible to prepare a long list of suitable keys and to designate each key by an *indicator* inserted in the cryptogram in a prearranged position. Indicators may be words, numbers, groups of letters, or single letters. For example, each key in a list of 500 may be indicated by a single pair of letters inserted at the beginning, at the end, or at any prearranged position of the cryptogram. This procedure has a disadvantage, however: if an error occurs at the particular position of the cryptogram containing the indicator, the decryptographing is made difficult if not impossible. For this reason indicators, if used, are often inserted in at least two positions in the cryptogram, usually at or near the beginning and end.

d. The letters of the plain text may be inscribed in the rectangle according to any one of the routes indicated in figure 1. If the transcribing process is accomplished by reading whole columns or whole rows, according to a prearranged plan which follows a route perpendicular to the inscribing route (except in the case of spiral inscription), the decryptographing process is simple. Only certain of the simpler combinations of inscription and transcription are suitable for military use, the most practicable being those illustrated in figures 5 and 6.

28. Columnar Transposition with Incompletely Filled Rectangles

a. The degree of cryptographic security of columnar transposition is much increased if the rectangle is *not completely filled.* It is impossible to go into the reasons for this increased security without demonstrating solutions; suffice it to say that the solution will be more difficult than would be suspected if one or more cells are vacant in the last row of the rectangle. An example of cryptographing and decryptographing is shown in figure 7.

b. To decryptograph such a cryptogram one must first count the number of letters in the text and then outline on cross-section paper a rectangle which will exactly contain the message, crossing off the cells which must remain vacant. In the foregoing example, the text contains 30 letters and, since the key contains 7 letters, the outlined rectangle is as

REF ID:A56932

shown in figure 8 of (a). From the complete rectangle $7 \times 5 = 35$ cells, 5 cells must remain vacant at the end.

c. The cipher text is then inserted in key-number order, the result of inserting the first two groups of the text being shown in (b), figure 8. It is only after the process has been finished that the complete message becomes apparent.

Message:

REQUEST IMMEDIATE REENFORCEMENTS

Key word: P – R – O – D – U – C – T
Numerical key: 4 – 5 – 3 – 2 – 7 – 1 – 6

R	E	Q	U	E	S	T
I	M	M	E	D	I	A
T	E	R	E	E	N	F
O	R	C	E	M	E	N
T	S					

Cryptogram:

SINEU EEEQM RCRIT OTEME RSTAF NEDEM

Figure 7.

Cryptogram:

SINEU EEEQM RCRIT OTEME RSTAF NEDEM

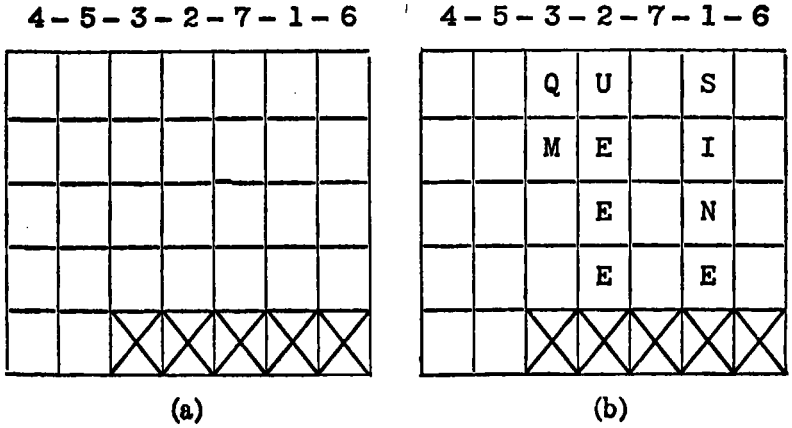

Figure 8.

REF ID:A56932

29. Modification of Columnar Method

A variation of the columnar procedure, but one that produces exactly the same results, may be found useful. First, write the message in groups corresponding to the length of the key. Thus, using the same key and message as in paragraph 28, the following is obtained:

```
4-5-3-2-7-1-6 | 4-5-3-2-7-1-6 | 4-5-3-2-7-1-6 | 4-5-3-2-7-1
R E Q U E S T | I M M E D I A | T E R E E N F | O R C E M E
4-5
T S
```

The letters are then taken from the groups and are transcribed in groups of five, all letters marked 1 being taken first, then all those marked 2, and so on. Thus, the first two cipher text groups are SINEU EEEQM, and the complete text is identical with that produced in figure 7.

30. Addition of Nulls to Complete a Final Group

The example given in the preceding case happened to contain 30 letters, a number that is an exact multiple of five. Thus, the final group in the cryptogram automatically became a complete group. For accuracy, the final group of every message should be complete; therefore, if the number of letters in the text of a message is not a multiple of five, it should be made so by the addition of nulls, *before* the transposition process is applied (see par. 23*b*).

Section III. MISCELLANEOUS TRANSPOSITION METHODS

31. Transposition Systems Employing Special Designs

a. Triangles, trapezoids, and other polygons are among the many designs used to produce transposition ciphers. Most of them, however, are impractical for wide military use but are used occasionally by secret agents.

b. A grille is a common transposition device of some practical importance. There are several types and one of the most common is that known as the *rotating* grille. It is usually made of a square sheet of cross-section paper from which cells have been cut in definite but apparently irregular positions. The grille is superimposed on another sheet of cross-section paper of the same dimensions and the letters of the message are written in the cells exposed by the perforations. Usually the grille is then given a 90° turn clockwise or counterclockwise, as agreed, and the fresh cells exposed by the perforations are filled with the next few letters of the text. If the grille has been prepared properly it is possible to give it four turns of 90° each, at the end of which all the cells on the under sheet of cross-section paper are occupied by letters. The grille is then removed and the letters of the sheet underneath it are transcribed in accordance with some prearranged route to form the cipher text. Natur-

REF ID:A56932

ally, the correspondents must have identical grilles and every step must be definitely prearranged. Although it is possible to construct grilles with many different arrangements of perforations, the necessity for carrying the device on the person, and the many agreements and understandings necessary for its successful operation make the method hardly suitable for field military use. Furthermore, practical difficulties connected with the preparation and distribution of many grilles would make it almost inevitable that several messages would be enciphered by the same grille. The degree of cryptographic security afforded by them is not so great as may be suspected; sometimes single messages of fair length may be solved.

32. Polyliteral and Word Transposition

a. Thus far only individual letters, as units for the transposition process have been discussed. It is possible to use pairs of letters, sets of three or more letters, or entire words as units; procedures are the same in monoliteral and polyliteral transpositions. Sometimes more complicated routes may be followed in transposition; for example, a route may be a prearranged succession of moves made by a knight in chess. It is usually necessary to have at hand a printed form showing the complete route, and this makes these methods impractical for field use. They may, however, be used in special cases.

b. The cipher system used by the Federal Army in the Civil War represents a good example of word transposition. In the earliest form in which this cipher was used by the Federals only one route was used, which consisted in writing the text in six columns, going up the sixth, down the first, up the fifth, down the second, up the fourth, and down the third. Arbitrary words were substituted for proper names, nulls were introduced at regular positions, and words even often misspelled for further obscurity. For example, the word "operation" was often spelled as two words: "opera," and "shun." Later, many additional routes were provided, relatively long lists of arbitrary equivalents for names, numbers, dates, common military terms, etc., were added, and the whole system was made considerably more complicated. While the security afforded by this system was probably ample for those days, it would hardly be sufficient today to permit its use even in cases where a delay of only a few hours is required. Furthermore, if long lists of arbitrary equivalents must be handled, the system presents all the disadvantages of a poor cipher system with but few of the advantages offered by a good code system.

33. Single and Double Transposition Methods

In single transposition methods the letters go through only one transposition from plain text to cipher text. It is possible to take the letters

REF ID:A56932

resulting from a first transposition and apply a second transposition to them; cryptograms so prepared often present a very great degree of security. Triple and quadruple transposition is possible but wholly impracticable for common use. Only a very limited number of double transposition methods are practicable for military use, but the degree of security afforded by certain of them is much greater than that afforded by certain much more complicated substitution methods.

34. Factors Concerning Use of Transposition Systems

a. The transposition methods described above provide a wide range of cryptographic security; in some there is very little security, in others there is a great deal. All transposition systems usually present important advantages in speed and simplicity. These advantages have led to attempts to increase security in some manner or other; double transposition schemes, rotating grilles, and other more complicated methods have consequently been developed. In only certain types are written memoranda or devices required. Very often the entire cryptographing process in even very complex methods may be easily memorized by persons of very good intelligence, such as secret agents. For these reasons transposition systems are often useful in espionage and counterespionage activities.

b. But transposition ciphers for military usage present three very serious disadvantages. In the first place, the methods are such that they do not allow any latitude for errors in handling. Often if a single letter is omitted or added, as not infrequently happens in telegraphic transmission, the whole message becomes difficult if not impossible to decryptograph. In the second place, if two or more messages prepared in the same key and *containing exactly the same number of letters* are available for study, no matter how complicated the method employed, the cryptograms can be solved, and the key recovered, and applied to other cryptograms in the same key but with different numbers of letters. In military cryptography it is not unusual, in cases of heavy traffic, to have as many as 100 or 200 messages transmitted on the same day, all in the same key. Control from a central headquarters of the exact message length would obviously be impossible. The chances, therefore, that the enemy may actually intercept and find several messages of identical length are not negligible. Thus, a transposition method presenting an extremely high degree of cryptographic security when only a few messages are to be cryptographed fails seriously when employed for heavy traffic. Finally, in certain cases, where the double transposition produces a great degree of security, it is almost inevitable that a poorly trained or careless cryptographic clerk will fail to perform both steps correctly. Not only messages prepared by one poor or careless operator, but all other messages, even though correctly prepared, are thus laid open to solution.

REF ID:A56932

CHAPTER 3
ELEMENTARY SUBSTITUTION SYSTEMS

Section I. GENERAL

35. Fundamental Nature of Substitution Methods, Cipher Systems and Code Systems

Methods now to be described differ from those above in that elements or textual units composing the original plain text retain their relative positions, but not their identities, and are replaced by other elements or textual units so that the external form of the writing is cryptographic in nature. For this reason these methods are called *substitution methods.* They may deal with individual letters, pairs of letters, sets of letters in regular groups, syllables, whole words, phrases, and sentences. Substitution methods may accordingly be subdivided into *letter methods, syllable methods,* and *word methods,* as in the case of transposition methods; but such a classification is a rather arbitrary one and is not based on the nature, form, or external appearance of the cryptographic text. For example, a substitution method dealing with single letters of the plain text may not involve their replacement by other single letters. In some cases whole words may be used to replace single letters. Outwardly, such a cryptogram gives the appearance of dealing with words, but its internal nature is quite clear: single-letter substitution has been effected. The classification indicated is, nevertheless, a useful one. When the cryptographic process involves the treatment of individual letters or pairs of letters, and only exceptionally the treatment of syllables or whole words, the method is known as a *substitution cipher system;* and when the process involves the treatment of whole words, phrases, or sentences, and only exceptionally the treatment of individual letters, groups of letters, or syllables, the method is known as a *code system,* because it usually necessitates the use of a *code book.*

36. Nature of Alphabets

a. The simplest kind of substitution cipher is that which is known in literature as Julius Caesar's Cipher, but which, as a matter of fact, was a favorite long before his day. In this cipher each letter of the text of a message is replaced by the letter standing the third to the right of it in the ordinary alphabet; the letter A is replaced by D, the letter B by E, and so on. The word CAB becomes converted into FDE which is cipher.

REF ID:A56932

b. The English language is written by means of 26 simple characters called *letters* which, taken together and considered as a *sequence of symbols,* constitute the *alphabet* of the language. Not all systems of writing are of this nature. Chinese writing is composed of about 44,000 complex characters, each representing one sense of a word. Whereas English words are composite or polysyllabic and may consist of one to eight or more syllables, Chinese words are all monosyllables and each monosyllable is a word. Written languages of the majority of other civilized peoples of today are, however, alphabetic and polysyllabic in construction, so that principles discussed here apply to all of them.

c. The letters composing the English alphabet used today are the results of a long period of evolution, the complete history of which may never fully be known. They are conventional symbols representing *elementary sounds,* and any other simple symbols, so long as the sounds which they represent are agreed upon by those concerned, will serve the purpose equally well. If taught from early childhood that the symbols $, *, and @ represent the sounds "Ay," "Bee," and "See," respectively, the combination @$* would still be pronounced CAB, and would, of course, have exactly the same meaning as before; or suppose that two persons have agreed to change the sound values of the letters, F, G, and H, and after long practice have become accustomed to pronouncing them as "Ay," "Bee," and "See," respectively. They would then write the "word" HFG, pronounce it CAB, and see nothing strange whatever in the matter. But to others not party to their arrangements HFG constitutes cipher. The combination of sounds called for by this combination of symbols is perfectly intelligible to the two who have adopted the new sound values for those symbols and therefore pronounce HFG as CAB, but HFG is utterly unpronounceable and wholly unintelligible to others who are reading it according to their own long established sound-symbol basis. It would be stated that there is no such word as HFG, which would mean merely that the particular combination of sounds represented by this combination of letters has not been adopted by convention to represent a thing or an idea in the English language. Thus it is seen that, in order for the written words of a language to be pronounceable and intelligible to all who speak that language, it is necessary, first, that the sound values of the letters or symbols be universally understood and agreed upon and, secondly, that the particular combination of sounds denoted by the letters should have been adopted to represent a thing or an idea. Spoken plain language consists of vocables; that is, combinations and permutations of elementary speech-sounds which have by long usage come to be adopted and recognized as representing definite things and ideas. Written plain language consists of *words;* that is, combinations and permutations of simple symbols, called letters, which represent visually and call forth vocally the elementary speech-sounds of which the spoken language is composed.

REF ID:A56932

d. It is clear also that in order to write a polysyllabic language with facility it is necessary to establish and to maintain by common agreement or convention, equivalency between *two* sets of elements, first, a set of elementary sounds and, second, a set of elementary symbols to represent the sounds. When this is done the result is what is called an *alphabet,* a word derived from the names of the first two letters of the Greek alphabet, "alpha" and "beta."

e. Theoretically, in an ideal alphabet each symbol or letter would denote only one elementary sound, and each elementary sound would invariably be represented by the same symbol. But such an alphabet would be far too difficult for the average person to use. It has been conservatively estimated that a minimum of 100 characters would be necessary for English alone. Attempts toward producing and introducing into usage a practical, scientific alphabet have been made, one being that of the Simplified Spelling Board in 1928, which advocated a revised alphabet of 42 characters. Were such an alphabet adopted into current usage, in books, letters, telegrams, etc., the flexibility of cryptographic systems would be infinitely extended and the difficulties set in the path of the enemy cryptanalysts vastly increased. The chances for its adoption in the near future are, however, quite small. Because of the continually changing nature of every living language, it is doubtful whether an original perfect alphabet could, over any long period of time, remain so and serve to indicate with great precision the exact sounds which it was originally designed to represent.

37. Normal Alphabets and Cipher Alphabets

a. In the study of cryptography the dual nature of the alphabet becomes apparent. It consists of two parts or components, (1) an arbitrarily arranged sequence of symbols.

b. The ***normal alphabet*** for any language is one in which these two components are the ordinary sequences that have been definitely fixed by long usage or convention. The dual nature of our normal or everyday alphabet is often lost sight of. When we write A, B, C, . . . we really mean:

Sequence of sounds:	"Ay"	"Bee"	"See"	. . . .
Sequence of symbols:	A	B	C	. . . .

Normal alphabets of different languages vary considerably in the number of characters composing them and the arrangement or sequence of the characters. The English, Dutch, and German alphabets each have 26, the French 25, the Italian 21, Spanish 27 (including the digraphs *ch* and *ll*), Russian 31. The Japanese language has a syllabary consisting of 72 syllabic sounds, to express which 48 characters are employed.

c. A ***cipher alphabet*** or a ***substitution alphabet,*** as it is sometimes called, is one in which the elementary speech-sounds are represented by

REF ID:A56932

characters other than those representing them in the normal alphabet. These characters may be letters, figures, signs, symbols, or combinations of them.

d. A more technical definition of a familiar cipher may now be given: When the plain text of a message is converted into encrypted text by the use of one or more cipher alphabets, the resultant cryptogram constitutes a *substitution cipher.*

38. Two Components of an Alphabet

It is convenient to designate that component of a cipher alphabet constituting the sequence of speech-sounds the *plain component,* and the component constituting the sequence of symbols the *cipher component.* If the plain component is omitted in a cipher alphabet, the latter is understood to be the normal sequence. For brevity and clarity, a letter of the plain text, or of the plain component of a cipher alphabet, is designated by suffixing a small letter "p" to it: A_p means A of the plain text, or of the plain component of a cipher alphabet. Similarly, a letter of the cipher text, or of the cipher component of a cipher alphabet, will be designated by suffixing a small letter "c" to it: X_c means X of the cipher text, or of the cipher component of a cipher alphabet. The expression $A_p = X_c$ means that A of the plain text, or A of the plain component of a cipher alphabet, is represented by X in the cipher text, or by X in the cipher component of a cipher alphabet.

39. Standard and Mixed Cipher Alphabets

In the arrangement or sequence of letters forming its cipher component, cipher alphabets are of two kinds:

a. Standard cipher alphabets, in which the sequence of letters in the cipher component is the same as the normal, but reversed in direction or shifted from its normal point of coincidence with the plain component.

b. Mixed cipher alphabets, in which the sequence of letters or characters in the cipher component is no longer the same as the normal in its entirety.

40. Enciphering and Deciphering Alphabets

All cipher alphabets may be classified on the basis of their arrangement as *enciphering* or *deciphering* alphabets. An enciphering alphabet is one in which the sequence of letters in the plain component coincides with the normal sequence, and is arranged in that manner for convenience in encipherment. In a deciphering alphabet the sequence of letters in the cipher component coincides with the normal, for convenience in deciphering. For example, in figure 9, (a) shows a mixed cipher alphabet arranged as an enciphering alphabet; (b) shows the corresponding

REF ID:A56932

deciphering alphabet. An enciphering alphabet and its corresponding alphabet present a *verse and inverse* relationship to each other. To invert a deciphering alphabet is to write the corresponding enciphering alphabet; to invert an enciphering alphabet is to write the corresponding deciphering alphabet.

Enciphering Alphabet

(a)
Plain: ABCDEFGHIJKLMNOPQRSTUVWXYZ
Cipher: JKQVXZWESTRNUIOLGAPHCMYBDF

Deciphering Alphabet

(b)
Cipher: ABCDEFGHIJKLMNOPQRSTUVWXYZ
Plain: RXUYHZQTNABPVLOSCKIJMDGEWF

Figure 9.

Section II. MONOALPHABETIC SUBSTITUTION SYSTEMS

41. Single-Alphabet Substitution

If a message is enciphered, letter-for-letter, by using one cipher alphabet which has been drawn up for the purpose, the resulting cryptogram is said to be enciphered by a single alphabet and to be a single-alphabet, or *monoalphabetic,* substitution cipher. More complex ciphers may use several alphabets in the enciphering of a single message. When two or more cipher alphabets are used, the resulting cryptogram is said to be a *polyalphabetic* cipher.

42. Standard Alphabet Ciphers

a. Standard cipher alphabets are of two sorts:

(1) *Direct standard,* in which cipher component is the normal sequence but shifted to the right or left of its point of coincidence in the normal alphabet. Example:

Plain: ABCDEFGHIJKLMNOPQRSTUVWXYZ
Cipher: QRSTUVWXYZABCDEFGHIJKLMNOP

It is obvious that the cipher component can be applied to the plain component at any one of 26 points of coincidence, but since the alphabet that results from one of these applications coincides exactly with the normal alphabet, a series of only 25 (direct standard) cipher alphabets results from the shifting of the cipher component.

REF ID:A56932

(2) *Reversed standard,* in which the cipher component is also the normal sequence but runs in the opposite direction from the normal. Example:

Plain: ABCDEFGHIJKLMNOPQRSTUVWXYZ
Cipher: QPONMLKJIHGFEDCBAZYXWVUTSR

Here the cipher component can be applied to the plain component at any of 26 points of coincidence, each yielding a different cipher alphabet. There is in this case, therefore, a series of 26 (reversed standard) cipher alphabets.

b. It is often convenient to refer to or designate one of a series of cipher alphabets without ambiguity or circumlocution. The usual method is to indicate the particular alphabet to which reference is made by citing a pair of equivalents in that alphabet. For example, the reversed alphabet above, one of a series of 26 related alphabets, may be designated as that in which $L_p = F_c$ or $W_p = U_c$. But the most common basis of reference is the letter which represents the first or initial letter of the plain component, usually A_p. Thus, the key for the cipher alphabet just referred to, as well as that preceding it, is $A_p = Q_c$, and it is said that the key letter for the cipher alphabet is Q_c.

43. Reciprocal Alphabets

a. The cipher alphabet in paragraph 42*a* (2) is also a *reciprocal alphabet;* that is, the equivalents show reciprocity and are reversible or reciprocal in pairs. For example, in the alphabet referred to, $A_p = Q_c$ and $Q_p = A_c$; $B_p = P_c$ *and* $P_p = B_c$, etc. The reciprocity exists throughout the alphabet and is a result of the method by which it was formed.

b. A series of related reciprocal alphabets may be derived by juxtaposing at all possible points of coincidence two components which are identical but progress in opposite directions. This holds regardless of whether the components are composed of an even or an odd number of elements. The reciprocal alphabet (par. 42*a* (2)) is one of such a series of 26 alphabets.

c. A single or isolated reciprocal alphabet may be produced in one of two ways:

(1) By constructing a complete reciprocal alphabet by arbitrary or random assignments of values in pairs. That is, if A_p is made K_c, then K_p is made A_c; if B_p is made R_c, then R_p is made B_c, and so on. If the two components thus constructed are slid against each other no additional reciprocal alphabets will be produced.

(2) By juxtaposing a sequence comprising an *even* number of elements against the same sequence shifted exactly half way to the right (or left), as seen below;

REF ID:A56932

ABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZ
ABCDEFGHIJKLMNOPQRSTUVWXYZ

d. A reciprocal alphabet is an inverse alphabet, since it may serve either as an enciphering or deciphering alphabet.

44. Procedure in Encipherment and Decipherment

a. When a message is enciphered monoalphabetically, that is, by means of a single cipher alphabet, letters of the text are replaced by the equivalents in the cipher alphabet selected by prearrangement. Example:

Message: THREE MACHINE GUNS CAPTURED.
Enciphering Alphabet: Reversed Standard, $A_p = D_c$
Plain: ABCDEFGHIJKLMNOPQRSTUVWXYZ
Cipher: DCBAZYXWVUTSRQPONMLKJIHGFE
Letter-for-letter encipherment:

THREE MACHINE GUNS CAPTURED
KWMZZ RDBWVQZ XJQL BDOKJMZA

The cipher text is then grouped in fives and the indicator letter D[6] inserted as the initial letter of the first group (or any other prearranged group).

Cryptogram:

DKWMZ ZRDBW VQZXJ QLBDO KJMZA

Figure 10.

b. The procedure in decipherment is merely the reverse of that in encipherment. The initial letter of the message, D, indicates $A_p = D_c$ in the cipher alphabet. The deciphering alphabet is therefore as follows:

Cipher: ABCDEFGHIJKLMNOPQRSTUVWXYZ
Plain: DCBAZYXWVUTSRQPONMLKJIHGFE
The message deciphers thus:
Cipher: (D) KWMZ ZRDBW VQZXJ QLBDO KJMZA
Plain: THRE EMACH INEGU NSCAP TURED

The deciphering clerk rewrites the text in word lengths:

THREE MACHINE GUNS CAPTURED

c. When a mixed alphabet is used, the enciphering and deciphering processes are the same as those described under *a* and *b* above. For speed in cryptographing, the cipher alphabet is prepared in the form of an enciphering alphabet, and for speed in decryptographing, in the form of a deciphering alphabet.

[6] If this or any such similar convention has been agreed upon by the correspondents.

REF ID:A56932

Section III. TYPES OF MIXED CIPHER ALPHABETS

45. Systematically Mixed Cipher Alphabets

It will be recalled that in a mixed cipher alphabet the sequence of letters or characters in the cipher component does not correspond to the normal sequence. There are various methods of mixing up the letters of the cipher component, and those which are based upon a scheme that is systematic in its nature are very useful because they make possible the derivation of one or more mixed sequences from any easily remembered word or phrase, and thus do not necessitate the carrying of written memoranda. They are called *systematically mixed cipher alphabets.*

46. Key-word Mixed Alphabets

a. One of the simplest types of systematically mixed cipher alphabets is the *key-word mixed alphabet.* The cipher alphabet consists of a key word or phrase (with repeated letters, if present, omitted after their first occurrence), followed by the letters of the alphabet in their normal sequence (with letters already occurring in the key, of course, omitted). Example, with GOVERNMENT the key word:

Enciphering alphabet....
Plain: ABCDEFGHIJKLMNOPQRTSUVWXYZ
Cipher: GOVERNMTABCDFHIJKLPQSUWXYZ

b. Mixed alphabets formed by including all repeated letters of the key word or key phrase were common in Edgar Allan Poe's day but are impractical because they make decipherment difficult.

Enciphering alphabet....
Plain: ABCDEFGHIJKLMNOPQRSTUVWXYZ
Cipher: NOWISTHETIMEFORALLGOODMENT

Deciphering alphabet....
Cipher: ABCDEFGHIJKLMNOPQRSTUVWXYZ
Plain: P VHMSGD QKAB OEF C
L J RWYN I
X T Z
U

The average cipher clerk would have considerable difficulty in decryptographing a cipher group such as TOOET, each letter of which has three or more equivalents, and from which the plain-text words (N) INTH, ..FT THI (S), IT THI . . . , etc., can be formed on decipherment.

c. An example of a key-word mixed alphabet is shown in figure 9, where, in its enciphering form, the cipher component presents to the experienced eye the skeleton of the key upon which the alphabet is based: WESTERN UNION TELEGRAPH COMPANY. Any easily remembered word, phrase, or sentence may be used. The starting point of the sequence, when used as a cipher component, may be indicated in the usual manner. For example, in the alphabet referred to, the

REF ID:A56932

alphabet key is $A_p = J_c$. Two or more correspondents using the prearranged key, WESTERN UNION TELEGRAPH COMPANY, would obtain the same disarranged sequence; when this sequence is to form the cipher component of a cipher alphabet, the prearranged key letter $A_p = J_c$ would result in giving each correspondent exactly the same cipher alphabet. The key words or phrases need not consist of any definite number of letters, but it is advisable to use for keys such words or phrases as will most thoroughly disarrange the normal sequence. (See, in this connection, par. 26.) A key-word mixed alphabet will manifest the key word or parts of it only when the alphabet is in the form of an enciphering alphabet. Note that alphabet (b) of figure 9 no longer gives any external evidence of having been derived from the phrase WESTERN UNION TELEGRAPH COMPANY.

47. Transposition-mixed Alphabets

a. It is possible to disarrange the sequence even more thoroughly by applying a simple method of transposition to the key-word sequence as if it were a message. An example is illustrated in figure 11.

Key word:

TELPHONY

(a) Simple columnar transposition:

TELPHONY
ABCDFGIJ
KMQRSUVW
XZ

Mixed sequence:

TAKXEBMZLCQPDRHFSOGUNIVYJW

(b) Numerical key, columnar transposition:

7-1-3-6-2-5-4-8
T E L P H O N Y
A B C D F G I J
K M Q R S U V W
X Z

Mixed sequence:

EBMZHFSLCQNIVOGUPDRTAKXYJW

Figure 11.

b. The last two systematically mixed cipher alphabets are *transposition-mixed alphabets.* Almost any of the methods of transposition described in sections IV and V of this chapter may be applied to them.

REF ID:A56932

48. Decimation Method of Forming Mixed Alphabets

Another simple method of forming a mixed alphabet is the *decimation method.* In this method, letters in the normal alphabet, or in a key-word mixed alphabet, are "counted off" according to a selected odd interval. As each letter is decimated—that is, eliminated from the basic alphabet by counting off—it is entered in a separate list to form the sequence of the mixed alphabet. For example, to form a mixed alphabet by this method from an alphabet based on the key phrase SING A SONG OF SIX PENCE with 7 the interval selected, proceed as follows:

a. Key-word (or basic) alphabet:

SINGAOFXPECBDHJKLMQRTUVWYZ

b. When the letters are counted off by 7's from left to right, F will be the first letter arrived at, H the second, T the third:

S I N G A O F X P E C B D H J K L M Q R T U V W Y Z
1 2 3 4 5 6 7 1 2 3 4 5 6 7 1 2 3 4 5 6 7

Fig. B

These letters are entered in a separate list (F first, H second, T third, etc.) and eliminated from the key-word alphabet.

c. When the end of the key-word alphabet is reached, return to the beginning, skipping the letters already eliminated:

S I N G A O F X P E C B D H J K L M Q R T U V W Y Z
6 7 1 2 3 4 5 6 7 1 2 3 4 5 6 7 1 2 3 4 5

Fig. C

d. Mixed alphabet.

FHTIEMZPQNDWCVBSLXAGOKYJRU

49. Random-Mixed Alphabets

Practical considerations, of course, set a limit to the complexities that may be introduced in constructing systematically mixed alphabets. Beyond a certain point there is no object in further mixing. The greatest amount of mixing by systematic processes will give no more security than that resulting from mixing the alphabet by random selection, such as by putting the 26 letters in a box, thoroughly shaking them up, and then drawing the letters out one at a time. Whenever the laws of chance operate in the construction of a mixed alphabet, a thorough disarrangement is bound to be produced. Random-mixed alphabets give more cryptographic security than do the less complicated systematically mixed alphabets because they afford no clues to positions of letters, given the

REF ID:A56932

positions of a few of them. Their chief disadvantage is that they must be reduced to writing, since they cannot readily be remembered, nor can they be reproduced at will from an easily remembered key word.

50. Number of Single Alphabets Available from a Basic Alphabet

It is obvious that the cipher component of a cipher alphabet may be shifted or slid against the plain component at 26 points of contact so as to produce a series of different enciphering alphabets. For example, the mixed sequences given under (b) of figure 11, when used as a cipher component, yields the following two of a series of 26 cipher alphabets:

Enciphering Alphabets

(1)
Plain: ABCDEFGHIJKLMNOPQRSTUVWXYZ
Cipher: EBMZHFSLCQNIVOGUPDRTAKXYJW

(2)
Plain: ABCDEFGHIJKLMNOPQRSTUVWXYZ
Cipher: WEBMZHFSLCQNIVOGUPDRTAKXYJ

The message DAILY REPORT NOT RECEIVED YET would be enciphered by the first alphabet as:

Plain: DAILY REPOR TNOTR ECEIV EDYET
Cipher: ZECIJ DHUGD TOGTD HMHCK HZJHT

and by the second alphabet as:

Plain: DAILY REPOR TNOTR ECEIV EDYET
Cipher: MWLNY PZGOP RVORP ZBZLA ZMYZR

Externally the two cryptograms seem different except in length. The two enciphering alphabets present the same sequence in the cipher component, but this entirely disappears in the corresponding deciphering alphabets, which are as follows:

Deciphering Alphabets

(1)
Cipher: ABCDEFGHIJKLMNOPQRSTUVWXYZ
Plain: UBIRAFOELYVHCKNQJSGTPMZWXD

(2)
Cipher: ABCDEFGHIJKLMNOPQRSTUVWXYZ
Plain: VCJSBGPFMZWIDLORKTHUQNAXYE

It is possible to write the same message in 25 different external forms, each using a different cipher alphabet of a series derivable from a basic sequence. The basic sequence or alphabet in such a case is often called a *primary sequence* or a *primary alphabet;* derived alphabets are called *secondary alphabets.* In producing secondary alphabets the basic sequence must be juxtaposed and slid against itself, or against the normal sequence, or against another mixed sequence. In all cases secondary alphabets form a series of alphabets that are interrelated and

REF ID:A56932

that either directly or indirectly manifest relationships which are important from a cryptanalytic point of view. It should be clear now that by means of a single, prearranged, secret word it is possible for two correspondents to send a whole set of messages all in different mixed alphabet, or to use a different alphabet for each of 26 consecutive days.

51. Miscellaneous Types of Cipher Alphabets

a. The cipher alphabets shown thus far have used only letters, but alphabets in which the cipher component consists of figures, or groups of figures, are not uncommon in military cryptography. Cipher alphabets using signs and symbols are not suitable for military cryptography because they can neither be telegraphed nor telephoned with any degree of accuracy, speed, or facility. Since there are but ten digits it is obvious that, in order to represent a complete alphabet in figure ciphers, combinations of at least two digits are necessary. The simplest kind of such an alphabet is that in which $A_p = 01$, $B_p = 02$, . . . $Z_p = 26$.

	1	2	3	4	5	6	7	8	9	0
1	A	B	C	D	E	F	G	H	I	J
2	K	L	M	N	O	P	Q	R	S	T
3	U	V	W	X	Y	Z	.	,	:	;

Figure 12.

b. Instead of a simple alphabet of the preceding type, it is possible to use a simple diagram of the type shown in figure 12. Here the digits at the side and top of the rectangle are used to designate, according to the coordinate system, the cell occupied by each letter and punctuation mark within the rectangle. When used for such purposes, the figures (or letters) constituting coordinate elements are referred to as ***row and column indicators***. It is usually necessary to agree beforehand upon which indicator will be given as the first half of the equivalent for a letter, the row indicator or the column indicator, in order to avoid ambiguity or error. In all of the systems to be described here, the row indicator will always form the first half of an equivalent. Accordingly in figure 12, the letter $A_p = 11$, $B_p = 12$, and so forth.

c. A variation of the foregoing diagram is exemplified in figure 13. Here, letters of the alphabet are inserted in the 25 cells of a large square, I and J being written together in one cell. Then a key word of five letters is applied to the top of the large square and the same or a different key word is applied to the side of the square to form column and row indicators. In figure 13, for example, S_p = TI; W_p = EH; etc.

REF ID:A56932

(2)

(1)		W	H	I	T	E
	W	A	B	C	D	E
	H	F	G	H	I–J	K
	I	L	M	N	O	P
	T	Q	R	S	T	U
	E	V	W	X	Y	Z

Figure 13.

The message RAIDERS HAVE GONE is enciphered thus:

Plain: R A I D E R S H A V E G O N E
Cipher: TH WW HT WT WE TH TI HI WW EW WE HH IT II WE

The cryptogram is then transmitted in groups of five letters:

Cryptogram: THWWH TWTWE THTIH IWWEW WEHHI TIIWE

d. In these two systems just described,

(1) The letters of the alphabet within the square or rectangle may be fixed in a mixed sequence, either systematically or random-mixed sequences being possible.

(2) The column and row indicators may be the same, or different; when letters are used they may form a key word or they may not; the key words, if formed, may be identical or nonidentical.

e. When letters are used as column and row indicators, they may be selected so as to result in producing cipher text that resembles "made-up words," that is, words composed of regular alternations of vowels and consonants. For example, if in figure 13 the row indicators consisted of the vowels A E I O U in this sequence from the top down, and the column indicators consisted of the consonants B C D F G in this sequence from left to right, the word RAIDS would be enciphered as OCABE FAFOD, which very closely resembles code of the type formerly called artificial code language. Such a system may be called a *false,* or *pseudo-code* system.[7]

[7] Prior to 1934, International Telegraph Regulations required code words of five letters to contain at least one vowel and code words of ten letters to contain at least three vowels. The Madrid Conference held in 1932 amended these regulations to permit the use of code groups containing any combination of letters. These unrestricted code groups were authorized for use after 1 January 1934.

REF ID:A56932

Section IV. MONOALPHABETIC SUBSTITUTION WITH VARIANTS

52. Purpose of Providing Variant Values

The individual letters composing ordinary intelligible plain text are used with varying frequencies; some, such as (in English) E, T, R, I, and N, are used much more often than others, such as J, K, Q, X, and Z. In fact, each letter has a *characteristic frequency* by means of which definite clues are afforded in the solution of simple substitution ciphers. This has led cryptographers to devise methods for disguising, suppressing, or eliminating the characteristic frequencies manifested by the letters of cryptograms produced by simple monoalphabetic substitution. One such method is that in which the letters of the plain component of the cipher alphabet are assigned two or more equivalents in the cipher component and they are, for this reason, called *variant values*. In some cases the letters of the plain component receive numbers of variant values, or variants, in proportion to their normal frequencies; in other cases, all the letters receive equal numbers of variant values, determined by the total number available.

53. Figure Ciphers with Variant Values

a. The use of figures in pairs as substitution equivalents makes available a total of 100 different pairs, those from 00 to 99. They may all be used in a complete system, or only certain ones may be selected, as prearranged.

b. One of the most common varieties of ciphers using all the pairs of digits is that in which the alphabet is reduced to 25 letters (by making I and J interchangeable or by eliminating a letter such as Q), and each letter is assigned four values which may be used at will. The assignment of values may be based upon a key word of four letters, each of which designates the starting points of a *normal sequence* of 25 numbers. An example is shown in figure 14, wherein the key word is TRIP. This means that in the first set of numbers, 01 to 25, the first number, 01, is assigned to the letter T; in the second set, from 26 to 50, the first number, 26, is assigned to the letter R; in the third set, from 51 to 75, the first number, 51, is assigned to the letter I; finally, in the last set, from 76 to 00, the first number, 76, is assigned to the letter P.

The letter A_p may be represented by any one of four equivalents, 08, 35, 68, and 87; the letter B_p by 09, 36, 69, 88; and so on. The equivalent used in any particular instance is selected at random, so that the word CAB may be represented in cipher by any one of a total of 64 combinations, such as 10–08–09, 70–35–09, 37–08–69, etc. In the final cryptogram

REF ID:A56932

the figures may be run together in groups of five. The cipher group 10080, on deciphering, would be split up into 10–08–0.

A—08 35 68 87	I–J—16 43 51 95	S—25 27 60 79
B—09 36 69 88	K—17 44 52 96	T—01 28 61 80
C—10 37 70 89	L—18 45 53 97	U—02 29 62 81
D—11 38 71 90	M—19 46 54 98	V—03 30 63 82
E—12 39 72 91	N—20 47 55 99	W—04 31 64 83
F—13 40 73 92	O—21 48 56 00	X—05 32 65 84
G—14 41 74 93	P—22 49 57 76	Y—06 33 66 85
H—15 42 75 94	Q—23 50 58 77	Z—07 34 67 86
	R—24 26 59 78	

Figure 14.

c. In this case, within each set of 25 the numbers progress serially, each set being treated as a ring or circle. It is of course possible to mix the sequence to destroy this serial progression, thus giving four mixed alphabets which can be used at random.

d. Another variation is to assign each letter a set of numbers in accordance with its relative frequency in ordinary English, so that each of the most frequently used letters such as E, T, R, I, and N will have perhaps seven or eight different equivalents, whereas letters of low frequency such as J, K, Q, X, and Z will each have but one equivalent.

54. Use of Rectangles to Provide Variant Values

a. Instead of drawing up alphabets as in figure 14, it is possible to use the diagram shown in figure 12, but with several variant digits as row indicators instead of a single digit for each row. For example, the row indicators may be of the following arrangements:

1–6–7	1–2–3	1–2–3	5–4–3
2–5–8	4–5–6	8–9–4	6–9–2
3–4–9	7–8–9	7–6–5	7–8–1, etc.

Thus, if the first arrangement is used, A_p would have the equivalents 11, 61, 71; B_p, 12, 62, 72; etc. The word RUN might be represented by any one of 27 different combinations, such as 28–31–24, 28–91–54, etc.

b. A variation of the foregoing system is that in which, by use of a diagram of the type shown in figure 13, a number of different letters are applied to each row and column, or 2-figure numbers may be used for this purpose. In this case a series of as many as 50 pairs of digits may be used as row indicators, and another series of 50 pairs as the column indicators.

c. The use of variants lends itself to application in a pseudo-code system such as described in paragraph 51*e*. It presents many possibilities for

REF ID:A56932

variation, with or without key words, with one or more alphabets distributed within the square or rectangle, with alphabets extended to include figures, punctuation signs, common syllables and words, etc. Some times pseudo-code is encountered when the groups of a numerical cipher system (or a figure-code system) are converted into letters, in order to make the cryptographic text conform to certain telegraph regulations and thus have the message accorded a more favorable rate of charge (sec. II, ch. 4). Thus, a group such as 0125784256 might be converted into the group BAFOSULAFE. If the conversion table is irregular in its construction and is kept secret, this adds an encipherment step to the system.

55. Disadvantages of Monoalphabetic Substitution with Variants

The obvious disadvantage of all such methods discussed in the preceding paragraph is that the cryptographic text is exactly twice as long as the original plain text. Furthermore, there is no compensating advantage from the standpoint of cryptographic security. When methods are such that the cipher equivalents are passed through another process which returns the cipher text to a length identical with that of the equivalent plain text, they are usually too complicated, too slow, and too subject to error to be practical. They are often the result of combining substitution and transposition processes in one system. Methods which substitute three or more characters for one letter of the original text are not at all practical for military cryptography.

Section V. POLYALPHABETIC SUBSTITUTION SYSTEMS

56. Monoalphabetic and Polyalphabetic Substitution

a. In the substitution methods thus far discussed it has been noted that only one cipher alphabet is used in the encipherment of a message, and that as a class they constitute the type of system designated as monoalphabetic substitution. It is true that in certain of the systems monoalphabetic substitution with variant equivalents takes place, there are two or more complete alphabets involved and that these systems may, therefore, with apparently good reason be designated as polyalphabetic substitution. This designation, however, will be seen to be somewhat inaccurate when cases of *true polyalphabetic substitution* come to be studied. The real or essential difference between the two systems may best be made clear by setting forth the primary object in each case.

b. In monoalphabetic substitution with variant values, the object of having different sets of equivalents is to suppress so far as possible by *simple* methods the characteristic frequencies of letters. One such method consists in merely providing one or more different values as cipher

REF ID:A56932

equivalents of the same plain-text letter, or a few different values as equivalents of some of the high-frequency letters. Now there are certain conditions inherent in the method itself, conditions which cannot here be indicated, that result in producing in the cryptograms certain definite clues leading to the rapid establishment, in cryptanalysis, of the equivalence of different variant values. Furthermore, in these systems the varying or alternative equivalents for plain-text letters are subject to the free choice and caprice of the encipherer. If he is careful and conscientious in the work he will actually make use of all the variant values afforded by the system; but if he is slip-shod and hurried in his work, he will use the same equivalent repeatedly rather than take pains and time to refer to his charts, tables, or diagrams to find variants. The result is that the cryptograms based upon these methods are open to easy solution, even when the basic methods are such as would make a solution difficult without the interception of carelessly enciphered messages. What is necessary is a system in which there is established a definite procedure for automatically shifting or changing the cipher alphabets employed in the encipherment of a single message; a method which within certain limits is beyond the momentary whims of cipher clerks, and which to a higher degree makes difficult the establishment of the equivalency of different cipher values. These are the objects of true polyalphabetic substitution systems. The number of such systems is large. Therefore, it will be possible to describe only a few of the more common or typical examples of methods practicable for military use.

c. The three methods (a) simple monoalphabetic substitution, (b) monoalphabetic substitution with variants, and (c) true polyalphabetic substitution, are attended by the following consequences in the plain text cipher relationship, a careful study of which will help to understand their similarities and differences:

(1) Encipherment—

In method (a) each plain-text letter is represented by one and always the same cipher equivalent.

In method (b) and method (c), each plain-text letter is represented by two or more different cipher equivalents, but in method (b) the variations are subject only to the whim of the encipherer, whereas in method (c) the identities of the cipher letters are determined by the positions they occupy in the text.

(2) Decipherment—

In method (a) and method (b), each cipher equivalent represents one and always the same plain-text letter.

In method (c) one and the same cipher equivalent represents two or more different plain-text letters, the identities of which are determined by the positions they occupy in the text.

REF ID:A56932

57. Example of Polyalphabetic Substitution

a. A simple example may be used to illustrate what is meant by true polyalphabetic substitution. Suppose that two correspondents agree upon a numerical key, for example, 74030274, each digit of which means that the plain-text letter to which the digit applies as a key number is to be replaced by the letter that stands a corresponding number of places to the right of it in the normal alphabet. For example, if R is to be enciphered by key number 7, it is to be replaced by Y. The numerical key is written under the letters of the plain-text letter for letter, and is repeated until the whole text is covered. Let the message be REENFORCEMENTS BEING RUSHED. The encipherment of a message is shown in figure 15. For convenience in counting forward (to the right) to find cipher equivalents, a normal alphabet is given at the top of the figure.

Normal alphabet: ABCDEFGHIJKLMNOPQRSTUVWXYZ
Plain: REENFORCEMENTS BEING RUSHED
Key: 74030274740302 74740 302747
Cipher: YIEQFQYGLQEQTU IIPRG UUUOIK
The text is then transmitted in *five-letter groups.*
Cryptogram: YIEQF QYGLQ EQTUI IPRGU UUOIK

Figure 15.

b. To decipher such a cryptogram, the clerk writes the numerical key over the cipher letters and then counts backward (to the left) in the normal alphabet as many places as indicated by the key number standing over each letter. Thus:

Normal alphabet: ABCDEFGHIJKLMNOPQRSTUVWXYZ
Key: 74030 27474 03027 47403 02747
Cipher: YIEQF QYGLQ EQTUI IPRGU UUOIK
Plain: REENF ORCEM ENTSB EINGR USHED
Message: REENFORCEMENTS BEING RUSHED

Figure 16.

58. Systematizing the Work

The work of encipherment may be materially shortened by systematizing the procedure. Instead of having to write the key over and over again in order to cover the text completely, the text may be written in sets of letters corresponding in length to the length of the key. Thus the text may be written underneath a single appearance of the key in successive short horizontal lines, leaving space between the lines for the insertion of cipher equivalents, as shown in figure 17a. Instead of enciphering the letters

7 4 0 3 0 2 7 4
R E E N F O R C
E M E N T S B E
I N G R U S H E
D

Figure 17a.

REF ID:A56932

by individual, repeated countings, two strips of paper bearing normal alphabets may be juxtaposed in the proper relative positions to encipher a whole *column* of letters at one setting of the strips. Thus, for the first column, with the key number 7, the strips are juxtaposed so that the first letter in the column, viz., R (which is to be represented by the seventh letter to the right of it, and is therefore to be enciphered by Y of the lower strip) is directly above Y, as follows:

Plain:
ABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZ
Cipher: ABCDEFGHIJKLMNOPQRSTUVWXYZ

The equivalents for the rest of the letters of the first column may now be rewritten down in their proper places, reference being made to the alphabet strips to see what the cipher letters should be: $E_p = L_c$; $I_p = P_c$; $D_p = K_c$. For the second column the two alphabet strips are in these relative positions:

Plain:
ABCDEFGHIJKLMNOPQRSTUVWXYZABCDEFGHIJKLMNOPQRSTUVWXYZ
Cipher: ABCDEFGHIJKLMNOPQRSTUVWXYZ

The cipher equivalents for the second column are: $E_p = I_c$; $M_p = Q_c$; $N_p = R_c$. The process is continued in this manner until all the columns have been enciphered, as shown in figure 17b.

7 4 0 3 0 2 7 4
R E E N F O R C Y I E Q F Q Y G
E M E N T S B E L Q E Q T U I I
I N G R U S H E P R G U U U O I
D K

Figure 17b.

The cipher text is then transcribed in groups of five letters, reading the successive lines in the normal manner, that is, from left to right and from the top downwards, yielding the groups YIEQF, QYGLQ, etc. It is

REF ID:A56932

no more difficult to encipher a message by this systematized procedure than by the longer and slower method of writing the text out in long lines and repeating the key over and over again. What is more important is that the shortened procedure promotes accuracy in encipherment. A few seconds careful checking of the relative positions in which the two alphabet strips are set is all that is required but this checking is very necessary, for if that is wrong all the cipher letters in that column to which this setting applies will be in error.

59. Using Key Words to Indicate Number, Identity, and Sequence of Cipher Alphabets Employed

a. If reference is made to the two settings of alphabet strips in paragraph 58, it will be noted that in the first setting $A_p = H_c$, in the second $A_p = E_c$. If the eight settings of the strips are studied it will be found that the letters which A_p represents successively are H, E, A, D, A, C, H, and E, giving the word HEADACHE. These settings, when first presented in the foregoing description, correspond merely to the numerical key 74030274, but this numerical key is also expressible in terms of letters, which when put together properly spell a word. This is only another way of showing that key words may be employed in this type of substitution as in those previously described. Key words of various lengths and composition may be used, consisting of single words, long phrases, or sentences. In general, the longer the key the greater is the degree of cryptographic security. The method as a whole is often referred to as the *repeating key method.*

b. The number of elements in the key—that is, the number of letters or figures composing it—determines the number of alphabets to be employed. The identity of each element of the key, the specific letter or figure it happens to be, determines specifically which of a set of cipher alphabets pertaining to the whole system will be used. And the specific sequence or relative order of the elements of the key determines specifically the sequence with which the cipher alphabets are employed within the encipherment. The total number of cipher alphabets pertaining to or composing the system may be limited or unlimited. When they are produced as a result of the sliding of two basic or primary alphabets against each other, the number is limited to 26 in the English alphabet.

c. A brief notation for indicating or designating a specific key letter is to suffix the subscript "k" to it, just as the subscripts "p" and "c" are suffixed to letters to indicate letters of the plain text or cipher text, respectively. When the key letter occurs in an equation, it can be enclosed within parentheses to avoid ambiguity. Thus, $B_p\ (D_k) = E_c$ means that plain-text letter B when enciphered by key letter D (in a certain alphabet system) yields the cipher letter E.

REF ID:A56932

60. Use of Other Types of Alphabets

a. It has been noted that in the case of monoalphabetic ciphers, alphabets of various types may be employed. This is likewise true of polyalphabetic ciphers. Instead of using two alphabet strips bearing the normal alphabetic sequence to determine the cipher equivalent of a letter enciphered by a given key number or key letter, one may use a pair of strips, one of which bears the normal direct, the other the normal reversed sequence. In the former case one is dealing with direct standard, in the latter, with reversed standard alphabets.

b. Polyalphabetic substitution with direct or reversed standard alphabets does not result in nearly so great a degree of cryptographic security as that resulting from the simple artifice of providing mixed alphabets for the strips. All sorts of mixed alphabets may be used. One of the strips may bear the normal direct or reversed sequence; the other a mixed sequence. Both strips may bear identical mixed sequences proceeding in the same direction, or in opposite directions. Finally, both strips may bear different mixed sequences.

c. In all cases, except where reciprocal alphabets are produced, it is essential that the correspondents agree upon the sequence or strip from which the plain and the cipher letters respectively will be taken, that is, it is necessary to indicate which sequence constitutes the plain component, which the cipher component. If this is not done, two correspondents will have difficulty in deciphering one another's messages. Also, as noted above, it is necessary to agree as to which letter the key letter is to be set against. The usual method is to agree that the initial letter of the plain component, usually A_p, will be set opposite the key letter, though other conventions are possible.

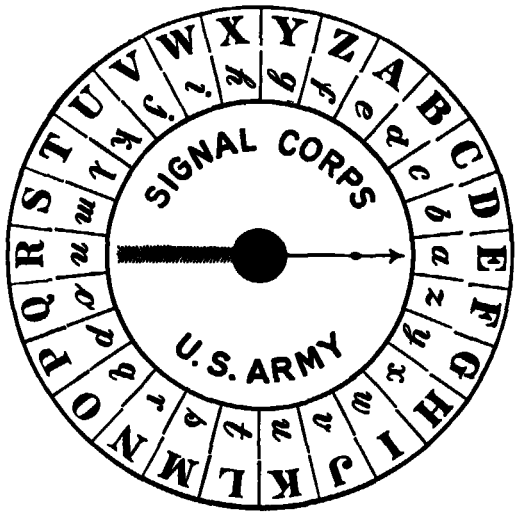
d. The sequences on the strips may be permanent or invariable, but naturally the degree of cryptographic security in this case is considerably lower than if they can be changed easily at the will of the correspondents and by prearrangement. It is possible that a secret word may serve as the basis not only for the key for shifting the strips, but also for the mixing of the alphabetic sequences. For example, two correspondents may agree to use the key CENTRAL AMERICA; to use the first part as the basis for constructing the mixed plain component; the second part, for constructing the cipher component; and to use the whole phrase as the key for enciphering the message. All the methods of constructing systematically mixed alphabets as described in section III of this chapter are applicable.

REF ID:A56932

Section VI. CIPHER DISKS AND SQUARE TABLES

61. Cipher Disks

a. In the foregoing section it was noted that the separate alphabets employed in the encipherment are produced by the use of only two strips of paper bearing the normal alphabet. Such strips are often referred to as *sliding alphabets,* because they can be shifted or slid against each other in any one of 26 points of contact or coincidence. Exactly the same results, so far as cipher equivalents are concerned, can be obtained by the use of other devices. First, there are the so-called cipher wheels or cipher disks in which an alphabet is written on the periphery of a *rotating* disk, the circumference of which is divided into 26 equal segments, and this disk is made to revolve concentrically upon a similar but slightly larger *fixed disk.* Figure 18 shows the now obsolete U. S. Army Cipher Disk, which is of this simple type. Here the alphabetic sequences are printed on glossy celluloid, are permanent, and admit of no variation. The use of unglazed celluloid upon which blank segments appear would permit of writing letters and erasing them as often as desirable. Thus, quick and easy change of alphabets would be possible.



To encipher a message, the key letter or the first letter of the key word or phrase is set opposite "a." Let us assume it to be "E." The cipher letters to be written are those opposite the text letter when "a" on the circle is set opposite "E" on the card. For example, "send powder" would be written "MARBPQIBAN." To use a key word or phrase, each letter is used in turn to encipher one letter only. When the last letter of the key word is used, repeat until all letters of the message are enciphered. Numbers when enciphered with the disk must be spelled out.

Figure 18.

REF ID:A56932

b. The cipher alphabets produced by the cipher disk shown in the figure are merely reversed standard alphabets, the same as are produced by the use of sliding strips of paper, and by the use of certain tables which are discussed below. The method of employing the disk needs no discussion. It may serve in monoalphabetic or polyalphabetic substitution with a key word or key number.

62. Square Tables

a. Tables known in the literature of cryptography under various names, such as "Vigenère Table", "Square Table", "Quadricular Table", "Pythagorean Table", "Cipher Square", "Cipher Chart", etc., are often employed in polyalphabetic substitution. All the results produced by their use can be duplicated by the employment of sliding alphabets or revolving disks. The modern form of the Vigenère Table is shown in figure 19. Such a table may be used in various ways, differing from one another in minor details. The most common method is to consider the top line of the table as containing the plain-text letters, the first column at the left as containing the key letters. Then each successive horizontal line con-

Figure 19. The Vigenère Table.

REF ID:A56932

tains the cipher equivalents for the plain-text sequence ABC . . . Z enciphered by the key letter which stands at its left in the first column. Thus, the cipher alphabet corresponding to key letter D is the sequence of letters in the fourth horizontal line under the plain-text line, where $A_p = D_c$, $B_p = E_c$, etc. It will be easy to remember, in using such a table, that the equivalent of a given plain-text letter, T_p, for example, enciphered by a given key letter, O_k, lies at the intersection of the vertical column headed by T, and the horizontal row begun by O. In this case $T_p\ (O_k) = H_c$. The same result will be found on referring to sliding, direct standard alphabets.

b. Minor modifications of the Vigenère Table are encountered. If the top line is made a reversed normal sequence, leaving the interior of the table unchanged, or if the successive horizontal rows are made to contain the reversed normal sequence, leaving the top row (plain text) unchanged, then the results given by using the table are the same as those given by using the obsolete cipher disk shown in figure 18. Again, the same general results can be obtained by using a set of alphabets in tabular form known under the names of Porta's Table and Napoleon's Table, which is shown in figure 20.

AB	A	B	C	D	E	F	G	H	I	J	K	L	M

	O	P	Q	R	S	T	U	V	W	X	Y	Z	N

Figure 20.

In this table the alphabets are all reciprocal, for example, $G_p\ (W_k) = V_c$, $V_p\ (W_k) = G_c$. Reciprocal alphabets when arranged in this form are sometimes called *complementary alphabets.* Note that in each alphabet either of two letters may serve as key letter indifferently: $G_p\ (W_k)$ or $G_p\ (X_k) = V_c$.

c. Another modification of the basic table, and one that employs numbers instead of letters as cipher equivalents is shown in figure 21. Since many more than 26 different equivalents are available (100 pairs of digits from 00 to 99, it is possible to insert many plain-text elements in

the top line of the table in addition to the 26 letters. For example, one could have the 10 digits; a few common double-letter combinations, such as DD, LL, RR, SS; a few of the most frequently used pairs of letters, such as TH, ER, IN, or even such common syllables as ENT, ING, and ION.

63. Square Tables Employing Mixed Alphabets

a. In the tables thus far shown the alphabets have been direct or reversed standard sequences, but just as mixed sequences may be written upon sliding strips and revolving disks, so can mixed alphabets appear in tabular form. The table shown in figure 22, based upon the key word sequence derived from the word LEAVENWORTH, is an example that is equivalent to the use of a strip bearing the same key word sequence sliding against another strip bearing the normal alphabet.

Figure 22.

The usual method of using such a table is the same as that in the preceding cases. The only difference is that the key letters must now be sought in a mixed sequence, whereas in the preceding tables they were located in normal direct or reversed sequences. Example, using figure 22: $C_p\ (S_k) = X_c$.

Figure 23.

b. Figure 23 illustrates a case in which a mixed alphabet is sliding against itself. The usual method of employing such a table is exactly the same as that explained before. The only difference is that both the plain-text letters and the key letters must be looked for in mixed sequences. Example, using figure 23: $U_p\ (R_k) = V_c$.

c. It has been indicated that the basis of reference in most cryptographic operations involving key words is the letter A_p. In employing sliding alphabets it is usual to set the key letter as located in the cipher component opposite the letter A as located in the plain component. But, as shown in paragraphs 42*b* and 60*c*, the key letter as located in the cipher component is usually set opposite the initial letter of the plain component. In all examples preceding that in figure 23, the key letter has been A. In figure 23, since the plain component is also a mixed sequence and its initial letter is Q, the sliding alphabets are set against each other so that the given key letter in the cipher component is opposite Q in the plain component. Thus, to duplicate the results given by the use of figure 23 in finding the value of $U_p\ (R_k)$, it is necessary to set the sliding strips in the following relative positions:

Plain: QUESTIONABLYCDFGHJKMNPRVWXZQUESTIONABLYCDEFGHJKM
Cipher: QUESTIONABLYCDFGHJKMNPRVWXZ

REF ID:A56932

Here it is seen that U_p $(R_k) = V_c$, which is identical with the result obtained from the use of the table. There are other ways of using the table, however, each having a correspondingly modified method of employing sliding strips in order to obtain identical results.

Section VII. OBSERVATIONS ON CIPHER SYSTEMS

64. More Complex Substitution Systems

a. The substitution systems discussed above are all based on relatively simple methods. They can all be solved rapidly. More complicated systems have been devised, however, and are used in certain situations. They are briefly described in this section.

b. Virtually all systems based upon the principle of a repeating key can be solved because of certain cyclic or periodic phenomena, which the use of a repeating key exhibits externally or internally in the cryptograms. There are methods for preventing the external manifestation in the cryptograms of these phenomena, or their suppression and disguise if present internally. In some, the principle is to make the elements of a fixed or invariable-length key apply to variable or irregular-length groupings of the plain text so that no cyclic phenomena are exhibited by the cryptograms. In others, the principle is to apply irregular lengths of the key, or a variable-length key to regular and fixed groupings of the plain text, with the same object in view. In still other methods, both principles are combined, or the key itself is of such a nature that it does not repeat itself. This may be brought about by constructing or establishing a nonrepeating key, or by employing the key in a special manner. Systems in which the successive letters of the cipher text or successive letters of the plain text after the initial letter serve as successive key-letters are also used with the object of avoiding or eliminating periodicity.

c. In the majority of the methods described the encipherment deals with single letters, and is therefore ***monographic*** in nature. There are, however, certain methods in which encipherment is by pairs of letters, called ***digraphic substitution,*** or by sets of three letters, called ***trigraphic substitution. Polygraphic substitution methods,*** as they are called, have for their object the suppression, so far as possible, of the characteristic frequencies of individual letters, by means of which solution may be reached. The methods may employ extensive tables, small squares, rectangles, and other designs, or sets of sliding or rotating alphabets. The ***Playfair Cipher,*** which was for many years a standard field cipher in the British Army and was for a short time during World War I employed by the U. S. Army, is an example of digraphic substitution.

REF ID:A56932

65. Combined Substitution-Transposition Systems

In paragraph 10*b*, reference was made to the possibility of combining within a single system both transposition and substitution methods; that is, of first enciphering by a method of one type and then taking the resulting cipher text and passing it through an encipherment of the other type. The usual order is first to substitute and then to transpose, but the reverse of this order of procedure is also possible. In some methods, quite complex, there may be a first substitution, then a transposition, and finally a substitution again. Despite the fact that three steps are involved, certain of these systems may be practical for military use under special conditions where speed is not as important as security. These cannot be described in this manual.

66. Cipher Devices and Cipher Machines

a. Only a little practical experience with any of the methods described is necessary to convince one that on the whole they are slow, more or less cumbersome, and subject to errors that often delay or make impossible the decryptographing of messages. Furthermore, from the point of view of cryptographic security, when employed in regular voluminous traffic they leave much to be desired. Consequently, cryptographers, both experienced and inexperienced, have been led to attempt to devise apparatus which will not only facilitate cryptographing and decryptographing, but will also increase the degree of cryptographic security. Small instruments constructed for this purpose, operated by hand, are called *cipher devices.* Scores of them have been devised, but only a few are sufficiently practicable for field use, and still fewer are of such construction that they produce cryptograms of unusual security. Among the better examples of such cryptographs is one which was for some years (1922–42) employed in the U. S. Army under the name of *Cipher Device, Type M–94.* Modern security requirements made such a device obsolete, however, and it has been replaced by a better one, the Converter M-209 ( ) (TM 11–380).

b. There are larger cryptographic machines which are much more nearly automatic in nature and can therefore be operated at a much greater rate of speed. These are usually equipped with typewriter keyboards which can be manipulated with considerable speed; the machine may also print the results of the enciphering or deciphering operations. Sometimes they are equipped with electrical transmitters and can thus serve not only to encipher and decipher messages but also to transmit them automatically. A mechanism of the latter nature is usually in the form of a modified printing telegraph machine, or else it consists of an auxiliary piece of apparatus used in conjunction with the teleprinter.

REF ID:A56932

Such apparatus can obviously be practicably employed only among the larger headquarters where traffic is sufficiently heavy to warrant its use.

67. Disadvantages and Limitations of Cipher Systems

Except for certain electrically operated cipher machines equipped with a typewriter keyboard, most cryptographic methods using "manual" or "pencil and paper" cipher systems are unsatisfactory for military purposes. Practically all such systems can be solved by enemy cryptanalysts, and those suitable for use in the theater of operations offer fewer obstacles to solution than systems suitable for use in the rear areas. Cipher systems are not economical in time units required in electrical transmission; the best that they can do is to produce cryptograms no longer than the original plain text. For use within small tactical units in the forward areas there are other cryptographic methods which offer advantages of speed, simplicity, and brevity and which, properly used, afford sufficient cryptographic security. These are often preferred over cipher methods in the forward echelons of the combat zone. These methods involve the use of lists of groups of letters or figures to which arbitrary meanings have been assigned. They are called "field codes," "prearranged-message codes," "brevity codes," "voice codes," "jargon codes," etc. Codes will be discussed in the succeeding sections of this manual.

REF ID:A56932

CHAPTER 4
ELEMENTARY CODE SYSTEMS

Section I. GENERAL

68. Difference Between Code and Cipher Systems as Methods of Cryptography

A code system is a more or less highly specialized form of substitution. The basic principle underlying substitution cipher systems is the replacement of the individual letter in the plain text of a message by other letters, figures, or symbols. Occasionally the replacement or substitution process is applied to groups of letters, and when this is done the groups are usually of definite, or regular length. In cipher systems the units with which the cryptographic treatment deals are the smallest of which plain text can be composed. The basic principle underlying code systems, however, is the replacement of entire words, long phrases, or complete sentences constituting the plain text of a message by arbitrarily selected equivalents having little or no relation to the elements they replace. These equivalents may be other words, groups of letters, groups of figures, or combinations. It is only exceptionally that the replacement or substitution process is applied to elements smaller than whole words, and when this is done the elements are single letters, groups of letters, or syllables. In code systems the units with which the cryptographic treatment deals are aggregates of smaller units—individual letters combined in various groups of irregular length; that is, words, phrases, sentences.

69. Code Books and Codes

a. If it were possible to memorize a long list of words, phrases, and sentences, together with the arbitrary equivalents called *code groups* assigned to represent them, there would be no need of having written or printed code books. In a code book, the words, phrases, and sentences are listed in a systematic manner and accompanied by their code equivalents. Correspondents must possess identical copies of the document in order to communicate with one another. An ordinary dictionary may, and often does serve the purpose of code communication, so far as single words are concerned, but as a rule a specially prepared document containing the words, phrases, and sentences, suited to particular types of correspondence, is used. Such documents are called, in the United States

REF ID:A56932

and in Great Britain, *code books* or, simply, *codes.* In other countries they are called *repertories, word books, cipher dictionaries, enciphering and deciphering tables, etc.,* although the term "code" is becoming prevalent throughout the world.

b. There are various types of codes each suited to particular types of correspondence. Some are large books used for general business or social correspondence; others are intended for particular industries—for example, rubber, sugar, steel, and automobile—and contain highly specialized technical vocabularies. Most large commercial firms have their own *private codes,* constructed especially for their use. This manual however, is concerned only with codes suitable for military communication. While the resemblances between the ordinary commercial codes and the usual military codes are marked, their primary purposes are different. Code is used in commercial communications principally to effect economy in cost of communicating, secrecy being of secondary importance. In modern military signal communications code is used to effect secrecy, brevity, and speed, especially in front-line signal communications. However, in lengthy administrative messages, the economy afforded by a properly constructed code is important.

70. Brevity Afforded by Code Systems

a. Messages cryptographed by means of a code book are secure only when the code book is kept secret. There are, however, code systems in which secrecy is not a factor. Such systems are intended for brevity or, in transmission by commercial telegraph, for economy. Code books afford a means for abbreviating or condensing the writing necessary to convey information. A single, comparatively short group of code characters may represent a whole word of as many as 15 or more letters, a long phrase, or a complete sentence. Thus, as a rule, the text of a code message is much shorter than the plain text, and therefore costs less to send. Naturally, the *condensing power* of a code book varies with the extensiveness of its *vocabulary,* since in a small book there can be listed only the most common words and only a few phrases and sentences; whereas, in a large book practically all the words likely to be used in telegraphic communication, and many common phrases and sentences may be included. When a code book is used to condense text only for purposes of economy, it is called a *nonsecret code.* Examples of such codes are the ordinary commercial codes sold in book stores. A code book may combine the features of economy and secrecy, in which case the book itself must be safeguarded from the enemy as a *secret code.*

b. In addition to money saving, code systems save time and labor in transmission and reception, as the number of characters handled in code systems is smaller than in cipher systems. The saving of time is an

REF ID:A56932

important factor in front line communications where speed is essential and sometimes outweighs security considerations.

c. In military cryptography, the greatest degree of condensation is afforded by "prearranged-message codes," "brevity codes," and the like. A *prearranged-message code* is a tactical code adapted to the use of units requiring special or technical vocabularies; it is composed almost exclusively of groups representing complete or nearly complete messages and is intended for shortening messages and concealing their content. A *brevity code* has for its sole purpose the shortening of messages. A *field code* is primarily a small tactical code which contains a large number of code groups representing words and a few common short phrases, from which sentences can be composed; a *syllabary,* which is a list of code groups representing individual letters, combinations of letters, or syllables, is usually provided for spelling out words or proper names, not present in the vocabulary; *numerical tables,* or lists of code groups representing numbers, dates, and amounts, are also included. A *jargon code* is another name for a simple, very short code in which bona fide dictionary words, baptismal names of persons, the names of rivers, lakes, etc., are used as code groups. A *voice code* is used for transmission by the small radio-telephone sets used in combat areas and may be a prearranged-message code, a brevity code, or a jargon code. Other names used to designate such codes are *combat code,* and *operations code.*

71. Operation of Encoding and Decoding

These two terms apply to the cryptographing and decryptographing respectively, of messages by means of a code. In encoding a message, a code clerk merely replaces the various words, phrases, sentences, and numbers of plain text by their code equivalents. The code text is built up from code units each representing the longest possible plain-text unit the code book affords. For example, if the sentence ENEMY FORCE ESTIMATED AT ONE BATTALION ENCOUNTERED ONE MILE SOUTH-EAST OF ROCK CREEK CHURCH is to be encoded, and the code book lists the phrase ENEMY FORCE ESTIMATED AT, the code group representing this phrase would be used rather than separate code groups representing the individual words ENEMY, FORCE, ESTIMATED, and AT, all of which might also be present in the code. The process of decoding is the reverse of that of encoding. Each code group is looked up in the code book, its meaning found and written down. Where the errors in transmission are few, the process is rapid; but even a small number of errors in a message may obscure the meaning or render a message unintelligible.

REF ID:A56932

Section II. CODE GROUPS

72. Composition of Code Groups

a. The elements of which code groups are composed may be of one or more of the following types:

(1) *Bona fide words*—real words taken from the dictionaries of one or more languages. The usual languages employed as sources for code words of this type are Dutch, English, French, German, Italian, Latin, Portuguese, and Spanish.

(2) *Artificial words*—groups of letters having no real meaning, constructed more or less systematically by arrangements of vowels and consonants so as to give these groupings the appearance and pronounceability of bona fide words.

(3) Groups of letters presenting no appearance of bona fide or artificial words and resembling cipher groups.

(4) Groups of arabic figures.

b. For special purposes, code groups composed of intermixtures of letters and figures within groups may be used. Call signs for radio stations, such as W2KA and W5AZZ, are examples of such intermixtures often used in radio call-sign codes. In certain highly specialized naval or military codes, the intermixture of letters and figures is sometimes necessary. Such intermixtures, however, are either not accepted or, if accepted, are charged for at a greatly increased rate when they appear in messages transmitted by commercial communications agencies.

c. A code may contain two or more parallel sets of code groups of different types. For example, in many commercial codes and in some military and naval codes, there is one series of code groups of the bona fide or artificial word type and another series of the figure-group type, both applying to the same series of words, phrases, and sentences of the code. There are several reasons for this. In most parts of the world where italic or roman letters are used for writing, letters possess greater advantages in accuracy of reading and handling by telegraph personnel. This is necessary for correct transmission and reception of messages. However, in some parts of the world—for example, Turkey, Russia, China—telegraph personnel, except in the large cities, are unfamiliar with the English alphabet and hence many errors in transmission arise. But arabic digits are almost universally recognized and used, so that for communications between obscure ports and small cities in foreign countries, figure groups are preferred over letter groups. There are certain methods of condensing code groups composed of figures into still smaller groups composed of letters by means of *condensers,* so that many firms use figure groups for such purposes in expensive transmissions. Finally, in certain methods of enciphering code messages for the sake of greater

REF ID:A56932

secrecy, figure groups often form the basis for the encipherment more readily than do letter groups.

d. Prior to 1 January 1934, in practically all modern codes constructed by experts, letter code groups were of the artificial-word type. On that date new rules in international communication became effective,[8] permitting the use of letter code groups without restriction in their formation, as class (3) in *a* above. It is probable that almost all of the codes published subsequently to the above date will contain letter code groups of the unrestricted type.[9]

e. The greatest advantage possessed by letter groups over figure groups lies in the availability of a far greater number of permutations, or interchanges, of letter groups, because there are 26 letters which may be permuted to form letter code groups, whereas there are only 10 digits which may be permuted to form figure groups. If code groups of five elements are used, then there are available 26^5, or 11,881,376 groups of five letters, and only 10^5, or 100,000 groups of five figures. Now since the number of permutations of 26 letters taken in groups of five is so great, only permutations conforming to special types may be selected for use, and there will still remain a sufficient number of code groups for even the largest codes. Certain types of code groups are selected so that possible error in telegraphic transmission can be reduced to a minimum. If the code groups have been constructed scientifically it is possible to correct such errors quickly without having the message repeated.

73. Length of Code Groups

The length of code groups used, whether the groups consist of two, three, four, or five elements, depends upon the size of the code. This applies almost exclusively to field military or naval codes, where transmission is through a governmental agency; in commercial messages or in governmental communications transmitted over privately-operated lines, five-letter or five-figure groups are used almost exclusively because of the regulations adopted by the International Telegraph Conferences and by commercial telegraph and cable companies. As a general rule in the transmission of code and cipher messages, each group of five letters is counted as one word regardless of the number and arrangement of vowels; each group of five figures is counted as one word.

74. Permutation Tables of Two-Letter Differential

a. Code groups of modern codes are constructed by use of tables which permit more or less automatic and systematic construction in the form desired. These are called *permutation tables.* Because they may be used

[8] See Telegraph Regulations, International Telecommunication Convention, Madrid, 1932.

[9] For a treatise on the development of codes see "The History of Codes and Code Language, the International Telegraph Regulations pertaining thereto, and the bearing of this history on the Cortina Report," by Major William F. Friedman, Sig.-Res., Government Printing Office, 1928.

REF ID:A56932

to correct most errors made in transmission or writing, such tables are usually included in the code book and are called *mutilation tables, garble tables, error-detector charts, etc.* Before the invention of permutation tables, code as a system of communication was not wholly reliable. Scientifically constructed tables, however, include a feature (see *b* below) which has remedied this fault to a great extent.

b. To make an error in a group of five letters is not unusual on the part of the average telegraph or radio operator. If a difference of only one letter distinguishes one code group from another in the same code, as ABABA and ABABE, then serious errors may be introduced in the meaning of a message, or the message may be made unintelligible by only a few transmission errors. If, however, every code group in the code book is distinguished from all other code groups in the same code by a difference of at least *two* letters, then there would have to be two errors in a single group and these two errors would have to produce a code group actually present in the code before a wrong meaning would be conveyed. This principle of making code groups within the same code differ from each other by a minimum of two letters is called the *two-letter differential.* It is most easily incorporated in code groups by constructing the permutation table to this end. The differential may be the absolute difference in the identities of two letters or the relative positions occupied by them. For example, BACOF, and BACUG differ from each other in the identities of the final pair of letters; considered as a *combination* of letters, the two groups present a two-letter difference. The two groups BACOF and BOCAF, however, differ in the relative positions occupied by two of their letters, but considered as a permutation of letters, these two groups as well as the two groups BACOF and BACUG, present a two-letter difference. In short, when at least two corresponding letters in a pair of code groups differ in their identities, the two code groups are said to present a 2-letter difference. Errors arising from the exchange of position of two letters, without a change in their identities, are referred to as errors of *transposition.* They are not unusual but fortunately, as a rule, they involve only letters which are either adjacent or alternate. For example, in the pair of groups BACOF and BOCAF there is a transposition of the alternate-letter type. In recent codes, attempts have been made to devise permutation tables which will eliminate one of the two members of every pair of groups which differ from each other by the mere transposition of two adjacent or alternate letters. Codes using groups based upon a permutation table will show the table and explain how to use it in correcting the usual mutilations of groups.

c. The use of the two-letter differential reduces the possibilities for constructing letter-code groups from 26^5 (11,881,376) to 26^4 (456,976), but, considering the advantages, the sacrifice is worthwhile.

d. Permutation tables for the construction of figure-code groups are similar in nature and purpose to tables for the construction of letter-code

REF ID:A56932

groups. However, because of the more limited number of characters available for permutations, the maximum number of 2-figure difference groups possible in a 5-figure code is 10^4, or 10,000.

Section III. ONE-PART AND TWO-PART CODES

75. Arrangement of Contents of Codes

a. In their construction or arrangement, codes are generally of two types:

(1) *One-part,* or alphabetical codes. The plain-text groups are arranged in alphabetical order accompanied by their code groups in alphabetical or numerical order. Such a code serves for decoding as well as for encoding.

(2) *Two-part,* or randomized codes. The plain-text groups are arranged in alphabetical order accompanied by their code groups in a nonalphabetical order. The code groups are assigned to the plain-text groups at random by drawing the code groups out of a box in which they have been thoroughly mixed, or by some other manner in which the element of chance operates. Such a list can serve only for encoding. For decoding, another list must be provided in which the code groups are arranged in alphabetical or numerical order and are accompanied by their meanings as given in the encoding section. For this reason a two-part code is often called a *cross-reference code.* The following brief extracts from typical one-part and two-part codes illustrate the difference between them:

One-part code.		Two-part code.			
		Encoding Section		Decoding Section	
ABABD	A	GAJVY	A	ABABD	Obstructed
ABACF	Abaft	TOGTY	Abaft	ABACF	Term
ABAHK	Abandon	FEHIL	Abandon	ABAHK	Zero
ABAJL	. . . . it	BAYLT	. . . . it	ABAJL	If it has not
ABALN	Abandoned	ZYZYZ	Abandoned	ABALN	To be sent by
ABAMP	. . . . by	NYSYZ	. . . . by	ABAMP	Acceding
ABAWZ	Abandoning	IFWUZ	Abandoning	ABAWZ	Building
ABBAD	Abandonment	RUMGO	Abandonment	ABBAD	Do not attempt
----------	----------	----------	----------	----------	----------
----------	----------	----------	----------	----------	----------
ZYZYZ	Zero	ABAHK	Zero	ZYZYZ	Abandoned

b. Between the two extremes are codes which have features of both; that is, complete sections may be arranged in random sequence, but within each section the contents are arranged in some systematic or logical order. This is true, however, only of some of the older codes. In modern types, the two-part construction is more common.

REF ID:A56932

c. When a strict alphabetical arrangement is used in the sequence of the phrases, the code is said to be a *strictly alphabetical code;* when the phrases are listed under separate headings based upon the principal word or idea in the whole expression, the code is said to be a *caption code.* The following extracts will serve to illustrate the two types:

Caption code	*Strictly alphabetical*
Assistance	Assistance
Give *assistance*	Assistance for
Require *assistance*	Assistance from
No *assistance* required	Assistance has been sent
Assistance has been sent	Assistance to
Assistance for	Assistant
Assistance from	Assisted
Assistance to	.....
Assistant	Give
Assisted	Give assistance
etc.	.....
	No
	No assistance required
	.....
	Require
	Require assistance

d. More precise and economical encoding is possible with a caption code than with an alphabetical code. With the caption code it is easier to assemble an extended variety of expressions and shades of meaning under specific headings than with the alphabetical code. On the other hand, the use of a caption code involves more time and labor in encoding, especially by untrained or unskilled personnel, than the use of an alphabetical code. Where the phraseology of communication is standardized or stereotypic, the most common expressions may be listed in an alphabetical code as readily as in a caption code. In both types of codes there may be tabulated material, such as tables of numbers, dates, equipment, geographical or personal designations, either forming isolated sections in the code or inserted in the vocabulary under appropriate headings.

e. Two-part codes are used by many governments for their secret diplomatic, military, and naval communications because the advantages they offer over one-part codes are greater than their disadvantages. The disadvantages are: a two-part code is harder to handle than a one-part code because it is at least twice as large in content, since each code group and each plain-text element must appear twice; the cost of printing is approximately double; the amount of labor in compiling a two-part code is nearly four times greater because of the necessity for preparing the accurate cross-reference arrangement which is its basic principle.

REF ID:A56932

76. Purposes of Two-Part Type of Code

a. The two-part code is a comparatively recent development in code systems. Its purposes are greater secrecy, and greater accuracy.

b. In a one-part code the plain-text groups progress from A to Z in a regular alphabetical sequence, accompanied by their code groups, also in a regular alphabetical or numerical sequence. If the word ABAFT is represented by a code group whose initial letter is A, or whose initial number is 1, then the word ABANDON will be represented by a group whose initial letter is also A, or whose initial number is also 1. In other words, the enemy cryptanalysts have definite clues to follow in breaking down the code because of the parallelism of the two sequences; the determination of the value of one code group affords definite clues to the value of many other code groups. In a two-part code, however, the word ABAFT might be represented by a group whose initial letter is T, or whose initial number is 8, and the word ABANDON might be represented by a code group whose initial letter is F, or whose initial number is 3. In other words, the two sequences are not alike in progression; hence the determination of the value of one code group will give no clues to the value of any other group.

c. In considering the greater accuracy of a two-part code over a one-part code, the following pair of phrases (in a hypothetical one-part code) are given as an example:

WOVAM	Will be ready to attack
WOVEN	Will not be ready to attack

Such an arrangement is subject to two sources of error. A code clerk working under great difficulties, in a hurry, may accidentally write down WOVAM instead of WOVEN as a result of the contiguity of the two sets of letters which are similar in appearance and are so close together on the page that his eye may take the group from the wrong line. Again, on account of the similarity in sound, his ear may deceive him into writing WOVEN when he should have written WOVAM. Now the meaning of the one group is the exact opposite of the meaning of the other and, since either meaning may fit in correctly with the context of the message, the error may remain undiscovered for some time, thus causing serious inconvenience or, in the case of combat, actual loss of life. Furthermore, although the making of two errors in a single group is rather unusual in transmission or reception, yet it does happen and, in such a case as the above, would not be detected. This is especially true in connection with tabular material such as lists of numbers, dates, and names, in which the context often fails to yield clues to the correction of garbles or errors, or to give conclusive evidence of the presence of an error. But in a two-part code such errors are improbable. In the first source of error mentioned above, the code clerk would be very much less

REF ID:A56932

likely to confuse two entirely different groups of letters; in the second source, if two errors are made in the transmission or reception, and if these errors involve two letters producing a group which actually has a meaning in the code, this meaning is so unlikely to fit in correctly with the context that its probability of occurrence may be negligible. Thus, if this sort of error does happen, the meaning of the group fails to fit in with the context and at once indicates an error. Knowledge of such an error, even if it is impossible to correct it, is more preferable than ignorance of its existence, with a possible action based upon incorrect decodement.

Section IV. ENCIPHERED CODE

77. Purposes of Enciphered Code

a. Sometimes the code groups of a code message undergo a further process of encipherment. The resulting cryptogram constitutes an *enciphered code message.*

b. It is desirable to use enciphered code in two instances:

(1) When the basic code has had wide distribution and the message might fall into unauthorized hands. Commercial codes sold in bookstores, and even special codes distributed widely throughout governmental offices, illustrate the type of code to which this added safety factor should be applied.

(2) When increased security is necessary for highly classified communications. Although the basic code book may already be secret, further encipherment would greatly delay the solution of the code if it fell into the hands of enemy cryptanalysts.

c. It has already been stated that code messages may be solved by cryptanalytic principles without possession of the code. The length of time required for the process varies widely, and is dependent upon the conditions under which the work is done (see ch. 1). To increase the length of time required for solution, as in secret codes, the code text of the messages resulting from the use of the code is passed through a cipher process so that the messages will be in different keys, thus delaying the assembling and study of data, which is necessary to the solution.

78. Types of Encipherment

a. Both of the two general classes of cipher methods, transposition and substitution, may be used in enciphering code. The increased degree of secrecy because of encipherment depends entirely upon the nature of the system applied.

b. Transposition systems involving a rearrangement of complete groups may be employed where the degree of increased security does not

REF ID:A56932

have to be of a high order, and where the original form of the groups must be retained even after encipherment. Transposition systems in which the order of the letters within groups is changed may also be employed. For example, a numerical key may indicate the transposed order of the letters of the code groups, so that a group such as XDFGY will become DFYXG.

c. Substitution systems of many sorts may be employed, ranging from simple monoalphabetic to the most complex types of substitution with cipher machinery. Tables of alphabets are often used. In some systems, a simple transposition process may be combined with a simple substitution process.

d. A favorite method in one-part codes having both letter-code and figure-code groups is that in which the letter-code group standing at a prearranged interval before or after the letter-code group representing the actual word or phrase intended to be conveyed is substituted. The interval may remain fixed within a single message, or it may vary according to some predetermined key. Numerical code groups make the use of large intervals practicable.

e. In modern practice, the most common methods of enciphering figure-code groups are those using addition or subtraction, with a *key book* containing arbitrary groups of figures. When such methods are properly used, they yield a high degree of security. The highest degree of security is attained when such a key book is used *only once.*

REF ID:A56932

CHAPTER 5
COMPARISON OF CODE AND CIPHER SYSTEMS

79. Advantages and Disadvantages of Each Type of System

a. From the viewpoint of purely military cryptography, a comparison of the advantages and disadvantages of each method can be made only between systems suitable for each of the following three general categories:

(1) High-security, or "high-grade," systems for cryptographic intercommunication among the largest military units and the highest echelons of command.

(2) Medium-security, or "medium-grade," systems for cryptographic intercommunication among the intermediate units and echelons of command.

(3) Low-security, or "low-grade," systems for cryptographic intercommunication among the small units and the lowest echelons of command.

b. The principal factors to be taken into account in comparing code and cipher methods in cryptographic communication are reliability, security, rapidity, flexibility, and economy.

(1) *Reliability.* Reliable cipher machines made possible by modern engineering and cryptographic techniques satisfy all or a majority of these factors to a great degree, and such machines are now used in the U. S. Army for these high-grade systems. Although the machines are complex, their reliability can be assured by having properly trained personnel to operate and maintain them. Accuracy is also one of the elements of reliability and a good cipher machine can yield a higher degree of accuracy or completeness of text in cryptographic communication than can a code system. A mistake in one or two code groups may obscure, alter, or render unintelligible the meaning of a whole message, but in cipher systems, often wrong letters may be corrected, or missing letters may be supplied, by the context. It must be remembered, however, that in some cipher systems a single error of a fundamental type, such as using the wrong key or the wrong "setting," may prevent the deciphering of the message.

(2) *Security.* If reliability were the only or the most important factor, code would be preferable to cipher for all echelons of

REF ID:A56932

command, because the simplicity of a code book is to be preferred to the complexity of a large cipher machine. But unenciphered code is not sufficiently secure for the communications of the highest echelons and headquarters. If encipherment must be added as a second step in the cryptographic process, it practically destroys the simplicity features of a code system; unless the enciphering method is fairly complex, it adds little security. In a properly designed cipher machine, embodying sound cryptographic principles based upon a thorough knowledge of cryptanalytic principles, the single-step-encipherment process can yield cryptograms of very great security. In a good code system, however, the solution of one or even of several messages does not entail the immediate breakdown of the entire system, with the consequent ability to read all messages, as is usually the case in a cipher system.[10] Codebooks, of course, can be rendered useless by compromise. Actual possession for a long period of time is not necessary; methods of rapid photography may be applied and a book of several hundred pages copied in a few minutes.

(3) *Rapidity.* The speed with which a cipher machine equipped with a typewriter keyboard can be operated leaves even simple, unenciphered code far behind in the matter of rapidity.

(4) *Flexibility.* Complete flexibility would permit cryptographing the originator's own language without change necessitated by the limitations that exist in all but the most extensive codebooks. Thus, a cipher machine is much more flexible than a code and can be used for all sorts of messages; whereas, in a code containing words, phrases, and sentences prepared for a specific type of communication, rewording the original text as written by the originator is often necessary, if the words, phrases, and sentences in the codebook are to be used; otherwise the original wording must be encoded word by word, or even syllable by syllable.

(5) *Economy.* Whether expressed in terms of money or manpower, cipher systems are more economical than code systems for high-echelon communications. Code text is usually shorter than the equivalent plain text, because it is condensed or abbreviated, but a single clerk operating a rapid cipher machine

[10] A good cipher system may be compared to a library housed in a large structure of many rooms with all doors and all windows securely locked. If an intruder can force an entry into the structure, he will find a master key which will open all the locks and give him access to *all* the books in the library. A good code system (especially a two-part code) may be compared to a library housed in a similar structure, but no two locks are alike and no master key is available or can be made. Therefore, the lock on *each* door must be worked at patiently as a separate problem. Thus, although the intruder may force his way into one room, this gives him access to only a small part of the library; in order to read all the books, he must force his way into each room, which takes much time, since each lock presents a separate and special problem.

REF ID:A56932

can turn out 10 to 15 times as much work as one operating a code system; furthermore, codes must be prepared, printed, and distributed. These steps take much time and labor and are often performed under considerable difficulty. A continuously operative code compilation section must be maintained to replace codes as fast as they become compromised by continued use, or by capture. The handling of the manuscript and proofs in printing entails the necessity of ever watchful secrecy; and finally, the prompt and thorough distribution of codes to all who must use them is sometimes very difficult, especially where the distribution must be made over an extensive territory. Therefore, for high-echelon cryptographing communications, ciphers are more economical than codes, but the economy factor is least important.

c. It is clear that high-grade systems should include all or as many as possible of the five factors listed in *b* above; moreover, the advantages afforded by good cipher machines make cipher systems more desirable than code systems for the high-grade cryptographic systems required by high-echelon cryptographic intercommunication. In addition, secondary or "back-up" systems must be provided so that in case of machine or power failure, there will be available some means for cryptographic communication. Finally, emergency systems must be provided for cryptographic communication when neither apparatus nor codebooks can be employed.

d. Medium-grade cryptographic systems for intercommunication among intermediate echelon commands must meet almost the same severe requirements as systems for intercommunication among high-echelon commands. Here again, cipher machines are preferable to code. The machines may not be so large or complex, but if the same basic cryptographic system is employed by both the high-grade and the medium-grade machine, many advantages are noted. The problems of manufacture, maintenance, instruction of personnel in the operation of the system, distribution of keying data, etc., are simpler if they are basically the same for both types of machines. Moreover, it is possible for a message from an intermediate command to be deciphered by a high-echelon command, and vice versa, without using a second cryptographic system. For these reasons, cipher machines are widely used in the U. S. Army for medium-grade cryptographic communication and, in addition, certain manual systems requiring simple types of apparatus are also used. These may serve also as the secondary or "back-up" systems required for the high-echelon cryptographic communications.

e. (1) Even in the so-called "low-grade" systems, cipher machines are serving the purposes for which field codes were formerly supplied. Converter M–209–( ) is a small, mechanical cipher machine widely used in the U. S. Army for communications

REF ID:A56932

within the small combat units. If properly used, it yields cryptograms of considerable security. It is a complicated device; it has no keyboard, and is slow in operation. Despite its reduced size and weight, this device is not convenient for use in front-line areas, nor is it suitable for use in voice communication by small radio-telephone equipments such as the "walky-talky" or "handy-talky" sets.

(2) Manual or hand-operated cipher systems are also unsuitable for such purposes. The processes of enciphering and deciphering by means of such systems require very close mental attention to avoid errors; the more secure methods are hopelessly slow and the faster ones are not secure, in comparison with the security that a small, frequently-changed *two-part* code yields.

(3) Practical experience indicates that in messages of very small tactical units, in certain types of air-to-air or air-to-ground communications, and in certain forms of messages where the subject matter is highly stereotypic, as in weather reports and fire-control observations, code is often preferred over cipher. In all these cases, speed must give way to security; size and weight of equipment are important factors; simplicity of operation under battle conditions is vital, which eliminates methods requiring much training and concentrated attention. Also, if code is properly prepared, one or two code groups may express a command or a report that would require many groups of cipher text. Small codes meet the requirements in all these respects, and for this reason, code is still used to some extent in the U. S. Army, especially in the forward areas.

80. Fundamental Assumption of Military Cryptography

It has been seen that every good cryptographic system combines two more or less separate and distinct elements: a basic or unchangeable method or process, which is termed the general system; and a specific or variable factor which controls the steps under the general system and is termed the specific key. The secrecy of any military cryptographic system must be entirely dependent upon the specific key because it *must be assumed that the enemy is in full possession of all the details concerning the general system.* This assumption is warranted by the whole history of military cryptography and is based upon the two following considerations which all experienced cryptanalysts regard as valid. In the first place, in military cryptography there are more prolific sources from which to obtain information concerning cryptographic methods than there are in the isolated methods used by private individuals. In fact, by one means or another, the enemy can sooner or later come into possession of full information regarding the general cryptographic system. In the

REF ID:A56932

second place, within a very short time the number of messages available for study becomes so great, and the inevitable blunders in the handling of communications have become so numerous that a solution by detailed study can always be made by the enemy, with a consequent disclosure of the general system. If a cryptographic system adopted for military use were such that messages in that system could be solved easily without the specific keys applicable to the messages once the underlying methods became known, the entire system would have to be changed, a new system devised, and thousands of persons in the military service trained in its operation. This, of course, would be impracticable. It is assumed that the enemy has knowledge of the general cryptographic system, its cipher devices, instruments, or machines. Only cryptographic documents which are given a limited distribution can be kept secret from the enemy, but they can be kept secret only for a variable length of time before they must be changed. These changes, as a rule, do not affect their method of usage. In cipher sytems, the specific key must be susceptible of easy and rapid changes by prearrangement between correspondents. In systems for use by secret agents or very small military parties in the theater of operations, the key may be an easily remembered word, phrase, sentence, or number; it must not require the carrying of written notes on the person. In systems for use by commanders of large and intermediate or even small headquarters in the theater of operations, the specific key may be in the form of written memoranda, paper tapes, and the like. Generally, the specific key must be the same throughout a given period of time for all the members of an intercommunicating network, or at least only a very limited number of specific keys must be in simultaneous effect; otherwise confusion and delay are inevitable. As a consequence of this requirement, the enemy may intercept a good many messages all in the same specific key. A cryptographic system for military use must conform to all requirements of practicability set forth in section IV, chapter 1, and to the foregoing section concerning the specific key; this system must be such that it is practically impossible for the enemy to solve any message quickly enough to make the information obtained of real or immediate value in the tactical situation, even though he is in full knowledge of the general method of the system, possesses the cipher device or apparatus, if used, and may have available for study 1,000 or more cryptograms sent on the same day. There is no single cryptographic system yet known which fully meets all these requirements, and in order to provide the necessary degree of security for a large army several different types of ciphers and cipher machines, as well as small codes for front line use, must be employed simultaneously.

REF ID:A56932

CHAPTER 6
CORRECTION OF ERRORS

81. Sources of Error in Cryptography

Errors, mutilations, and garbles are some of the names applied to the inaccuracies that occur in cryptographic communication. They are so common and so troublesome that commanders who, for the most part, already regard cryptographic processes as hopelessly slow and cumbersome, often become much prejudiced against their use in active operations. Therefore, instruction in the correction of errors is an essential part of the training of personnel assigned to cryptographic work. Training and experience will reduce the time necessary to correct the most common types of errors, which may be traced to the following sources:

a. Cryptographing and decryptographing, including the simple process of copying by hand or by typewriter.

b. Transmission and reception by all means of signal communication other than those in which the cryptograms are physically carried from origin to destination.

82. Practical Suggestions for Eliminating Errors

a. Errors in cryptographing and decryptographing can be much reduced though not wholly eliminated, by systematizing the work so far as possible and *invariably* checking it. Great care must be exercised in the formation of letters in writing, and roman capitals should always be used. If copied messages are checked for correctness by two operators, one reading the letters to the other, a phonetic alphabet must be used in order to prevent misunderstandings. In forward areas it is impossible to provide suitable or convenient quarters for personnel engaged in cryptographic work, but in rear areas and at the larger headquarters this personnel will work much more efficiently in a quiet, well ventilated office. To check the accuracy of cryptographic work it is always advisable, when possible, that an operator other than the original cryptographic clerk decryptograph the message. In checking his own work, an operator should actually decryptograph it—not merely check his cryptographing—because it is a psychological fact that persons have a tendency to repeat an error unconsciously. The most serious errors in cryptographic work leading to difficulties and delays in decryptographing are not the mere mistakes in the writing down of letters, but are errors of a fundamental nature which the operator says, when it comes back to him, "I don't see how I could

REF ID:A56932

have made it." Checking by actually decryptographing will usually eliminate such errors. At the destination, the *final copy* of a decryptographed message should invariably be checked against the *original* work sheets before being turned over to the addressee, and again preferably, by another operator. It is easy to omit the word NOT from a decoded message and to fail to note the omission, if the same operator merely reads over the decryptographed message. Here, again, psychological factors are involved, and clerks who are disposed to transpose letters and words, an unconscious habit of a peculiar psychological origin, must be especially careful in their work.

b. Carelessness in the writing of system and message indicators, or failure to insert them in their proper places in the message, will usually make prompt decryptographing of the received message difficult or impossible. They should be written with the greatest of care.

c. If an incoming message is partially or wholly unreadable, an attempt should be made to find the error in the faulty message. Often a message can be decryptographed by a simple expedient such as applying the key for the day preceding or following and correct date, or applying the daily key for a classification higher or lower and the correct classification. If, however, the garbled text still resists all efforts of correction, a procedure (service) message should be sent. The length of time one should continue with the attempt to break the faulty message before sending a service will depend upon the classification and precedence of the message, transmission problems involved, time required to complete service, etc.

d. The procedure in preparing and handling service messages dealing with errors in cryptographic messages is quite involved, in order not to compromise the cryptographic system or give clues as to the contents of the faulty message. Instructions covering the procedure to be followed in such servicing are issued from time to time and should be carefully followed.

e. The most important precaution to be observed, in order to avoid the transmission of messages which cannot be promptly decryptographed at the receiving end, is the rigid adherence to all instructions set forth in documents describing the cryptographic operations to be followed. Misunderstanding or ambiguity is rarely found in *properly prepared* documents detailing cryptographic operations, and a careful study and observance of the instructions will result in the preparation of messages without fundamental errors.

f. To be efficient in cryptographic work requires, in addition to the usual qualities of carefulness, accuracy, and attention to detail, the possession of certain psychological characteristics peculiar to the work. If absent, these characteristics as a rule cannot be developed, but if present they can be intensified and made more efficient by constant practice and experience. It is therefore advisable to select personnel for cryptographic work as for any other specialized work, to train them carefully, and

REF ID:A56932

retain them as long as possible; the longer they remain in this work the less likely they are to repeat the errors with which the work abounds and the more likely they are to render highly efficient service.

g. Errors in transmission and reception are frequently made, especially in transmission by radio, because of interference, atmospheric disturbances, and the like. Cryptographic clerks should be familiar with the Morse and Bandot alphabets and the most common errors of wire and radio transmission methods, so as to be able to refer an error to its probable origin or to find clues for the correction of badly garbled groups when all other means fail. The following tables will be found useful:

Most common errors in Morse transmission

International Morse alphabet (used in radio, cables, and outside United States)			American Morse alphabet (used in the United States, except for radio)

CHAPTER 7

FUNDAMENTAL RULES FOR SAFEGUARDING CRYPTOGRAMS

83. General

The rules given in this chapter are to be considered as a general guide only. Under actual operating conditions much is dependent upon special situations, and the specific cryptographic systems employed. Therefore, the particular rules and regulations currently in effect always will take precedence over those stated herein.

84. Fundamental Rules of Cryptographic Security

a. Failure to observe the fundamental rules of cryptographic security often makes possible the solution of cryptographic systems by enemy cryptanalysts. These rules apply to the originators of messages to be cryptographed as well as to cryptographic personnel. Detailed instructions for the writers of such messages are outside the scope of this manual. It is, however, desirable to indicate the following points:

(1) Stereotypic phraseology must be avoided, especially at the beginning and ending of a message. *The known or suspected presence of stereotypic phraseology constitutes the basis of many methods employed in cryptanalysis;* in some cases, indeed, the only possible method of solution makes use of the presence of stereotypic phraseologies, or, as they are often called, *cribs.* Operating instructions for currently authorized cryptosystems prescribe the application of measures which effectively reduce the dangers of stereotypic phraseology to the security of those systems; however, as an added precaution, routine reports of all kinds should be sent by agencies of signal communication not susceptible to interception.

(2) Special care must be taken to see that the messages are clear and concise. If a message is ambiguous or incomplete, unnecessary confusion results and the accuracy of the cryptographic operation is brought into question.

(3) Messages should be shortened by the deletion of unnecessary words. Conjunctions, prepositions, repetitions of words, and, especially, punctuation should be reduced to a minimum. When punctuation is necessary, it should be spelled out, either in full or in abbreviated form. Numbers should also be spelled out.

REF ID:A56932

Where letters of the alphabet must be used, as in certain symbols designating types of equipment, it may be necessary to represent these letters by their authorized phonetic equivalents, where it is essential that there be no possibility of error. Such spelling out however, should be reduced to a minimum.

(4) Authorized abbreviations should be used whenever practicable.

(5) Regulations regarding the manner of indicating addresses and signatures should be carefully followed.

(6) Regulations governing the security classification of messages (Top Secret, Confidential, Restricted) must be observed at all times.

b. Much of the success which attends the efforts of cryptanalysts is based upon ignorance and carelessness on the part of cryptographic personnel. Rarely are cryptographic blunders the result of willful violation of instructions; but if cryptographic personnel realize, that, by carelessness or ignorance, their own lives and those of thousands of their comrades are jeopardized, they will be more attentive to rules set up for their guidance. The most important of these rules are as follows:

(1) *Questionable messages.* Never cryptograph a message which, in the opinion of the cryptographer, violates any of the provisions or regulatons relating to the drafting of messages, until the question has been referred to and passed by someone with authority to change the message.

(2) *Mixing plain and cryptographic text.* Never allow cryptographic text with its equivalent plain language to appear in a cryptogram, and never mix plain and cryptographic text, *except in messages where such mixtures are specifically permitted.* This includes punctuation and abbreviations of any description. Such messages afford valuable clues to the enemy. If a message is to be cryptographed at all, it should be completely cryptographed.

(3) *Text of messages.*

(*a*) Never repeat in the clear the identical text of a message once sent in cryptographic form, or repeat in cryptographic form the text of a message once sent in the clear. Anything which will enable an alert enemy to compare a given piece of plain text with a cryptogram that supposedly contains this plain text is highly dangerous to the safety of the cryptographic system. Where information must be given out for publicity, or where information is handled by many persons, the plain-text version should be very carefully *paraphrased* before distribution, to minimize the data an enemy might obtain from an accurate comparison of the cryptographic text with the equivalent, original plain text. To paraphrase a message means to rewrite it so as to change its original wording as much as possible without changing the meaning of the mes-

REF ID:A56932

sage. This is done by altering the positions of sentences in the message, by altering the positions of subject, predicate, and modifying phrases or clauses in the sentence, and by altering as much as possible the diction by the use of synonyms and synonymous expressions. In this process, deletion rather than expansion of the wording of the message is preferable, because if an ordinary message is paraphrased simply by expanding it along its original lines, an expert can easily reduce the paraphrased message to its lowest terms, and the resultant wording will be practically the original message. It is very important to eliminate repeated words or proper names, if at all possible, by the use of carefully selected pronouns; by the use of the words "former," "latter," "first-mentioned," "second-mentioned"; or by other means. After carefully paraphrasing, the message can be sent in the other key or code.

(*b*) Never send the literal plain text or a paraphrased version of the plain text of a message which has been or will be transmitted in cryptographed form except as specifically provided in appropriate regulations.

(4) *Keys.* Never repeat in a different key or system, without paraphrasing, a cryptographed message which has once been transmitted, unless specifically authorized by the appropriate authority.

(5) *New cipher keys.* Never transmit a new cipher key by means of a message cryptographed in an old key.

(6) *Addresses or signatures.* Never place cryptographed addresses or signatures at the beginning or end of the cryptographed text. Bury them in the body of the message.

(7) *Identifying information.* Include in the address of a cryptographed message only the minimum information necessary for the message to reach the headquarters for which it is intended.

(8) *Replies.* Never reply to a cryptographed message in the clear.

(9) *Short titles.* Never use short titles as system or message indicators in cryptographed messages.

(10) *Dummy letters and padding.* Never use dummy letters or padding unless their use is specifically authorized.

(11) *System indicator.* Never encipher, encode, or disguise in any way the system indicator, unless specifically authorized.

(12) *Notations.* Never place on the cryptographed copy of a message any notations about the system or the subject matter of the message.

(13) *Work tables.* Never allow unnecessary materials such as books, documents, or papers to be on the work table during the process of cryptographing and decryptographing.

REF ID:A56932

(14) *Filing messages.* Never file cryptographic messages and their equivalent plain text together. Work sheets must be destroyed by burning.

(15) *Check for accuracy.* Cryptographed messages should be checked for accuracy by decryptographing the message before transmission. Whenever practicable, this should be done by a cryptographer other than the one who originally cryptographed the message.

(16) *Safeguarding material.* Observe all rules of physical security established to safeguard the cryptographic material and message translations. Utmost care should be taken to prevent the loss or unauthorized sight of the codes or lists of cipher keys in use. It is possible to photograph an entire code in two or three hours. Mere continued possession of the cryptographic material is, therefore, no absolute guaranty that it has not been compromised by photography or some other method of reproduction. The only absolute assurance of its not having been compromised is that it has *never* left the possession of the person into whose care it has been entrusted or the safe in which it is kept when not in use. Even if knowledge that a code or cipher has been compromised follows immediately after such compromise, the amount of time and the difficulties involved in notifying all concerned and distributing new cryptographic material are so great that serious damage is caused by the delay and interruption in communication, not to speak of the danger resulting from the enemy's reading the most recent messages in the compromised system.

(17) *Reporting compromise.* Finally, it must be realized that the compromise or capture of cryptographic material is a most serious matter. If there is any reason to suspect that such material or related documents have been compromised, higher authority should be notified by the fastest means possible. Not only is such material available to the enemy for reading current and old messages, but also the cryptanalytic data afforded thereby become most useful in working on similar systems to replace the compromised one. The failure to notify higher authority promptly, if compromise is suspected, may jeopardize the lives of thousands of soldiers and is therefore more serious than permitting compromise to take place, if it could have been avoided. Regulations for reporting compromise should be carefully observed at all times.

PART TWO
ADVANCED MILITARY CRYPTOGRAPHY

CHAPTER 8
TRANSPOSITION SYSTEMS

Section I. MONOPHASE TRANSPOSITION SYSTEMS

85. Transposition Systems Employing Geometric Designs

In part one brief mention was made of the use of geometric designs and figures other than rectangles in producing transposition ciphers. It was stated that triangles, trapezoids, and polygons of various symmetrical shapes can be employed. Figures of these types form connecting links between the methods that use simple rectangular designs and the more complicated methods that use figures in which transposition takes place along diagonals.

86. Trapezoidal Designs

a. A trapezoid or, more accurately, a truncated triangle, of prearranged dimensions as regards the number of cells (which in this case are rhombs into which it is to be partitioned, is constructed. There will be left on one side of the design a series of small triangles which are not to be used for inscribing letters, and are therefore crossed off in the design, as shown in figure 24. Only two agreements are necessary in order to fix the dimensions of the design: a keyword or keyphrase to determine the number of cells at the base of the design, and an understanding as to the height of the design expressed in number of cells. The successive horizontal rows of cells will decrease by one in number from bottom to top of the design. In figure 24, the keyphrase NO CANDY FOR ISSUE is used as a basis for deriving a numerical key of 15 elements, and it is assumed that by prearrangement it was agreed that the height of the design should be eight cells. Therefore, the bottom row has 15 cells, the next one upwards, 14, the next, 13, and so on, to the last, with 8 cells. The inscription may follow any route agreed upon; in the example, it follows the normal manner of writing. The transcription follows the numerical key order, yielding this cryptogram:

REF ID:A56932

ODAIK AEDME HPODV ITEIP NHUET BOBRO
HDTFS EISNI ETBEF BCBTM ESHGA RTORD
IRERE AWARR ERTNS IEPVR VASEO FTEDL
NA

b. Decryptographing is merely the reverse of cryptographing, there being no difficulties provided that the design has been correctly constructed. For this purpose cross-section paper will be found useful. The analysis of such a cryptogram is somewhat complicated by the presence of columns having varying numbers of letters; it may be further complicated by following complex routes in inscription. It is also possible

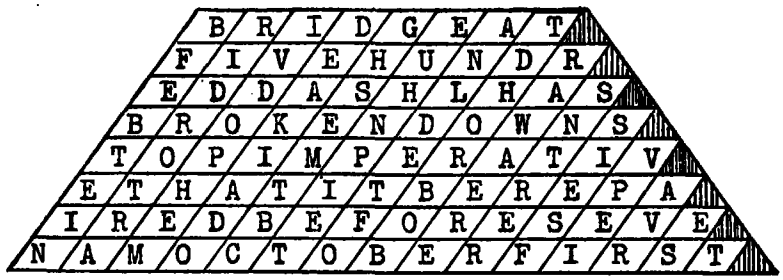

Figure 24.

to follow a numerical key in the inscription of the plain text in horizontal lines; this additional procedure would further complicate and delay solution.

87. Triangular Designs

a. The simplest way of drawing up a triangle for cryptographing is to take cross-section paper, draw a square the side of which is equal to the length agreed upon as expressed in the number of cells, and then draw a diagonal cutting the large square into two equal triangles. This is shown in figure 25, where the length agreed upon is nine, that is, nine cells per side. The letters of the plain text are inscribed in accordance with any prearranged route, the one illustrated in figure 26 being a simple method wherein the letters are inscribed in horizontal lines in the normal manner. When so inscribed, the letters in the diagram will form $2n - 1$ columns where n is the number of cells forming one of the sides of the square from which the triange has been constructed. The total number of letters that can be inscribed within

REF ID:A56932

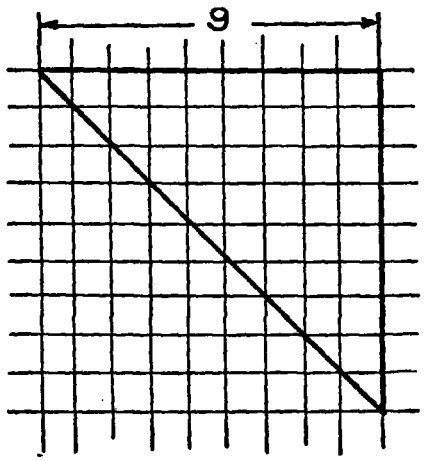

Figure 25.

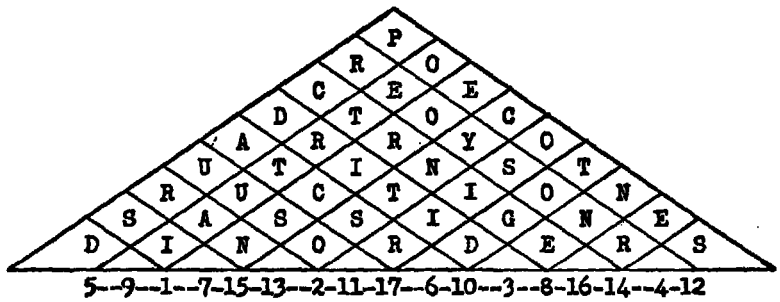
the triangle is the sum of $n + (n - 1) + (n - 2 + (n - 3) + \ldots + 1$. For a triangle based upon a side of 9 cells, the sum is $9 + 8 + 7 + 6 + 5 + 4 + 3 + 2 + 1 = 45$. The letters may then be transcribed to form the cryptogram by following another route, or by following a derived numerical key applied to the base of the triangle. A simple method of deriving a key of $2n - 1$ elements from a key of n elements or letters is exemplified herewith. Let the key be DIAGONALS, a word of nine letters. Extend this key to $2n - 1$ places by repetition, and then assign numerical values as usual:

$n = 9$; $\qquad 2n - 1 = 17$

	1-2-3-4—5—6-7—8—9-10-11-12-13-14-15-16-17
Keyword:	D I A G O N A L S D I A G O N A L
Numerical key:	5-9-1-7-15-13-2-11-17—6-10—3—8-16-14—4-12

This numerical key is the one that has been employed in enciphering the message in Figure 26.



Cryptogram:

UUSOC YNTSO REOYS ONRER
DRITI DTOGD RANEO RICSN
CTRNI GENNE ATCSR OSIIR
SOIET RTUAI POECO TNESS
DPRCD AURSD

Figure 27.

b. By a slight change in procedure it is possible to encipher a message and produce a text which, for the sake of accuracy in special cases, is double the original length, but which is self-checking. Suppose that instead of applying a single numerical key to the base of the triangle, a double-length key is applied to the legs, as shown in figure 27. Here the key is TRIANGLES, extended to double length by simple repetition, as follows:

	1—2-3-4—5-6-7-8—9-10-11-12-13-14-15-16-17-18
Keyword:	T R I A N G L E S T R I A N G L E S
Numerical key:	17-13-7-1-11-5-9-3-15-18-14—8—2-12—6-10—4-16

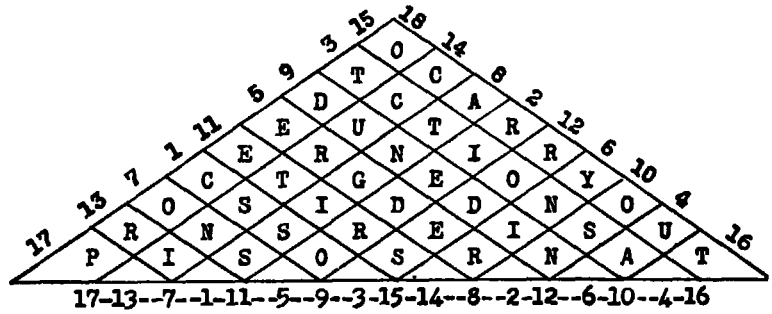
This key is applied to the legs of the triangle beginning at the lower left-hand corner. The transcription then follows key-number order, which results in doubling the length of the message but the repeated letters are scattered throughout the whole message. In decryptographing such a message the clerk merely omits the second occurrence of a letter if it agrees (in identity) with its first appearance in the text.

c. Many variations in inscription and transcription can be employed in the case of triangles as well as trapezoids. Some of the variations in the case of triangles are shown in figure 28.

88. Diagonal Methods

a. A method involving diagonal transposition which is reported to have been employed by the French Army in World War I is now to be described. A numerical key is derived from a fairly long word or phrase, and a rectangle is constructed, as in figure 29. The text is inscribed in this rectangle in normal fashion, nulls being employed, if necessary, to complete the last line of the rectangle.

REF ID:A56932



Inscription: Up left side, down right, alternately.

Transcription: (a) In rows from the base line, left to right and right to left, alternately, upwards:

Figure 29.

REF ID:A56932

b. The correspondents agree beforehand upon several diagonals which run from left to right, and from right to left and which intersect, thus cutting up the design quite thoroughly. In figure 29 let these selected diagonals be those indicated by the numbers from 1 to 6, inclusive, the odd ones indicating diagonals running from left to right. In the transcription, the letters along the indicated diagonals are first set down in groups of five, proceeding in key-number order. Correspondents must also agree beforehand as to whether a letter which lies at the intersection of two diagonals will be taken both times it is encountered or taken only once and, if so, whether on its first or second appearance. After all these letters have been written down, one then proceeds with the remaining letters in the usual columnar manner, omitting the letters which have already been taken. The cryptographing process will become clear upon the study of the example in figure 29.

89. Interrupted Keyword Transposition

a. This method of transposition is a development of a more simple method wherein the transposition follows a numerical key. The latter must first be described. A keyword or keyphrase of fair length is selected and a numerical key derived from it. Let this key be the phrase UNIFORMITY OF METHOD.

Keyphrase: U N I F O R M I T Y O F M E T H O D
Numerical key: 17-10-6-3-11-14-8-7-15-18-12-4-9-2-16-5-13-1

The plain text is then written out in horizontal lines corresponding to the length of the key; then transposition is effected *within each row,* according to the sequence of numbers applicable, as shown in figure 30.

Figure 30.

REF ID:A56932

b. In the foregoing case the encipherment takes place only by transposition within rows, but it is possible to complicate the method by transposing, in addition, the rows as a whole, employing the same key or only a portion of it, as much as is required. Thus, if the message contained 18 rows of 18 letters each, then the transposition of rows could be effected according to key-number order, the last row being taken first (since the number 1 of the numerical key happens in this case to be at the end of the numerical key), the 14th row being taken second (since the number 2 of the numerical key is the 14th number), and so on. Where the message does not contain as many complete rows as there are numbers in the key, the transposition takes place in key-number order nevertheless, the rows being taken in the numerical order of the numbers present. Using the same key and message as in the foregoing case, the encipherment would be as shown in figure 31.

Enciphering diagram:

Figure 31

c. From the preceding method it is but a step to the method of interrupted key transposition now to be described. Instead of writing the text in regular-length groups corresponding to the length of the key, it is written out in irregular groups the lengths of which vary according to some prearranged plan. For example, note the basis of the variable grouping in figure 32, which uses the same message and key as in *a* above.

d. This method may be combined with that shown in *b* above, thus further complicating the system. In decryptographing such a message it is best to use cross-section paper, block out the cells to be occupied by letters in the deciphering diagram, and indicate the key numbers applicable to each line. This will facilitate the process materially and help eliminate errors.

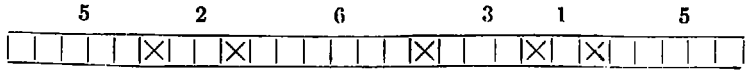
STMCD CDITD YREDR COEEO EARTN OSTAM
AOALL

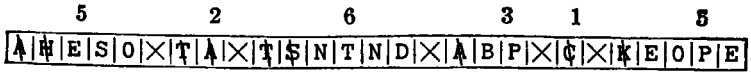
Figure 32.

e. Another method of interrupted transposition is that which employs a rather long sequence of digits to control the interruption. In order to avoid the necessity of carrying around such a written sequence, it is possible to agree upon a number whose reciprocal when converted by actual division into its equivalent decimal number will give a long series of digits. For example, the reciprocal of 7, or 1/7, yields a repeating sequence of *six* digits: 142857142857 . . .; the reciprocal of 49, 1/49, yields a repeating sequence of 42 digits, etc. Zeros, when they appear, are omitted from the sequence. Suppose the number 19 is agreed upon, the reciprocal of which yields the sequence (0)52631578947368421. On cross-section paper mark off sets of cells corresponding in number to the successive digits. Thus:



Let the message be ATTACK HAS BEEN POSTPONED.

Encipherment:



Cryptogram:

AHESO TATSN TNDAB PCKEO PE

REF ID:A56932

f. To decryptograph such a message, the cryptogram is written down in a series of cross-section cells, which are then blocked off in sets according to the numerical key:

5	2	6	3	1	5
A H E S O X T A X T S N T N D X A B P X C X K E O P E					

Taking the letters in consecutive order out of the successive sets, and crossing them off the series at the same time as they are being written down to construct the plain text, the message is found to begin with the following two words:

5	2	6	3	1	5
A H E S O X T A X T S N T N D X A B P X C X K E O P E					

ATTACK HAS . . .

g. Preparatory to cryptographing, it is necessary to find the length of the message to be enciphered and then to mark off as many cells as will be required for encipherment. Nulls are used to fill in cells that are not occupied after enciphering the whole message. The secrecy of the method depends, of course, upon the reciprocal selected, but there is no reason why any fraction that will yield a long series of digits cannot be employed. If the selection of key numbers were restricted to reciprocals, the secrecy would be more limited in scope than is actually necessitated by the method itself.

90. Permutation Method

a. An old method, known in literature as the *aerial telegraphy method,*[1] forms the basis of this system. A set of permutations of 3 4, . . . 9 digits is agreed upon and these permutations are listed in a definite series. As an example, let these permutations be made of the digits 1 to 5, selecting only four of the possible 120. Suppose those selected are the following, set down in successive lines of the diagram in figure 33a:

Permutation

2 3 1 5 4	2	3	1	5	4
3 2 5 1 4	3	2	5	1	4
1 5 3 2 4	1	5	3	2	4
4 3 1 5 2	4	3	1	5	2

Figure 33a.

[1] So named because it was first devised and employed in messages transmitted by a system of semaphore signaling in practical usage in Europe before the electrical telegraph was invented.

REF ID:A56932

The letters of the plain text, taken in sets of fives, are distributed within the sections of the diagram in accordance with the permutations indicated above the sections and also at the left. Thus, the first five letters of the text, supposing them to be the initial letters of the word RECOMMENDATIONS, are inserted in the following positions:

Permutation

2 3 1 5 4	2	3	1	5	4
	E	C	R	M	O

The next five letters are inscribed in the second line of the diagram in the sections indicated by the permutation above and at the left of the line. Thus:

Permutation

2 3 1 5 4	2	3	1	5	4
	E	C	R	M	O
3 2 5 1 4	3	2	5	1	4
	N	E	A	M	D

This process is continued for each line and for as many lines as there are permutations indicated at the left. In the foregoing case, after twenty letters have been inserted, one inserts a second set of five letters again on the first line, placing the letters of this second set immediately to the right of those of the first set, respectively in key-number order. The succeeding lines are treated in similar fashion until the whole message has been enciphered. The following example will illustrate the process:

Message: RECOMMENDATIONS FOR LOCATION OF NEW BALLOON POSITIONS MUST BE SUBMITTED BEFORE 12TH AIRDROME COMPANY CHANGES COMMAND POST TOMORROW.

Enciphering diagram:

Permutation

2 3 1 5 4	2	3	1	5	4
	EASEOM	CTIDMA	RCOTRM	MOIECD	OITBEN
3 2 5 1 4	3	2	5	1	4
	NOSRPS	ESNOMO	ANUTNT	MNOFOP	DFMEAT
1 5 3 2 4	1	5	3	2	4
	TESWYO	SLSTNR	OBBLHO	IWTECM	NAEFAR
4 3 1 5 2	4	3	1	5	2
	LNIRCB*	ROMISC*	FLUHGO	OPTDOD*	OOBAEW

* The letters B, C, and D are nulls, to complete the figure.

Figure 33b.

REF ID:A56932

The letters of the cipher text are taken from the diagram according to any prearranged route, the most simple being to transcribe the lines of letters in groups of fives, thus:

EASEO MCTID MARCO TRMNO IECDO ITBEN
NOSRP SESNO MOANU TNTMN OFOPD FMEAT
TESWY OSLST NROBB LHOIW TECMN AEFAR
LNIRC BROME SCFLU HGOOP TDODO OBAEW

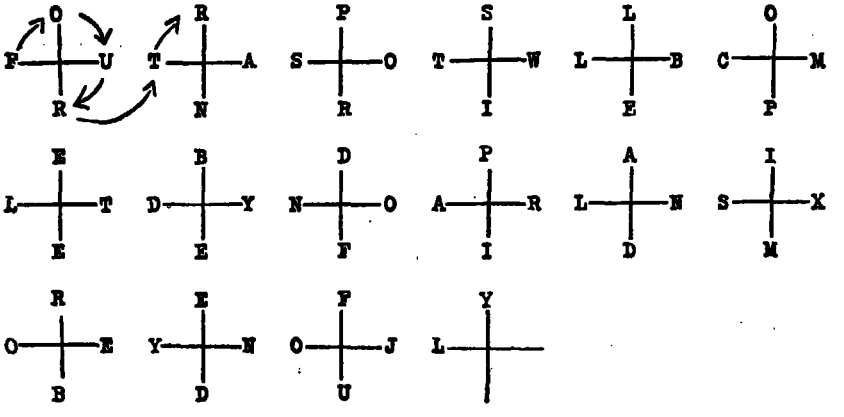
b. The foregoing method when employed in its most simple form does not yield cryptograms of even a moderate degree of security; but if the method of inscription and transcription is varied and made more complex, the degree of security may be increased quite noticeably. It is possible to use longer permutations, based on sets of 6, 7, 8, or 9 digits, but in every case the successive permutations must be prearranged as regards both their exact composition and their order or arrangement in the diagram.

91. Transposition Method Using Special Figures

a. The method now to be described is useful only in special cases where the correspondence is restricted to brief communications between a very limited number of persons. It is necessary to agree in advance on certain particulars, as will be seen. Let the message to be enciphered be the following:

FOUR TRANSPORTS WILL BE COMPLETED BY END OF APRIL AND SIX MORE BY END OF JULY.

Note the following figures and encipherment:



Cryptogram:

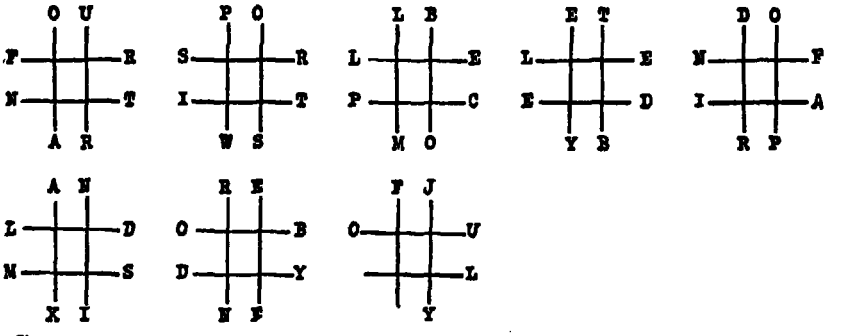
ORPSL OFUTA SOTWL BCMRN RIEPE BDPAI
LTDYN OARLN SXEEF IDMRE FYOEY NOJLB
DU

Figure 34.

REF ID:A56932

b. It will be noted that it is essential to agree in advance not only upon the nature of the figure but also upon the *number* of figures per line.

c. The next series is a modification of the preceding. The same message will be employed, with a double-cross figure, five figures per line.

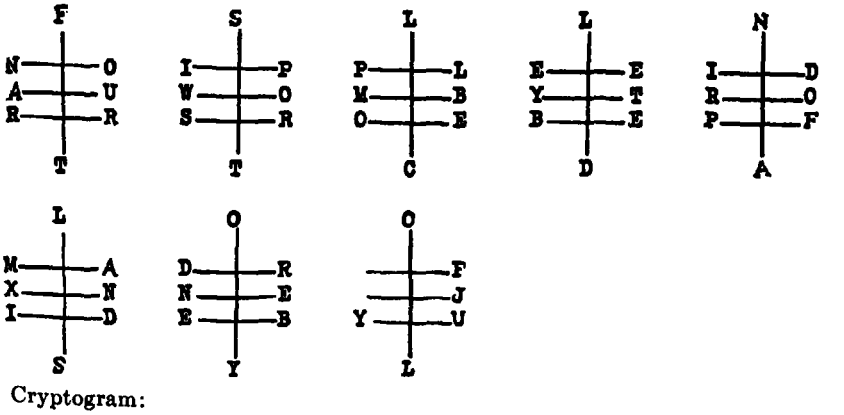


Cryptogram:

OUPOL BETDO FRSRL ELENF NTITP CEDIA
ARWSM OYBRP ANREF JLDOB OUMSD YLXIN
EY

Figure 35.

d. Still another series may be formed, as follows:



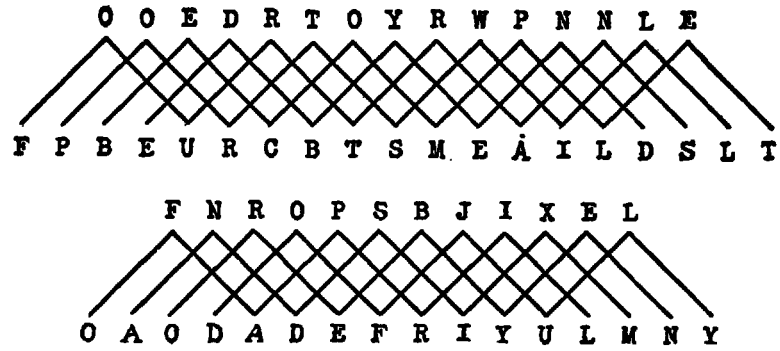
Cryptogram:

FSLLN NOIPP LEEID AUWOM BYTRO RRSRO
EBEPF TTCDA LOOMA DRFXN NEJID EBYUS
YL

Figure 36.

e. A figure of different form than the preceding forms the basis of the next type.

REF ID:A56932



Cryptogram:

OOEDR TOYRW PNNLE FPBEU RCBTS
MEAIL DSLTF NROPS BJIXE LOAOD
ADEFR IYULM NY

Figure 37.

f. From the foregoing examples, it is obvious that many other figures may be used for effective transpositions of this kind, such as stars of varying numbers of points, polygons of various symmetrical shapes, etc. It is merely necessary to agree upon the figures, the number of figures per line, the starting points of the inscription and transcription processes.

g. The method lends itself readily to combination with simple monoalphabetic substitution, yielding cryptograms of a rather high degree of security.

Section II. POLYPHASE TRANSPOSITION SYSTEMS

92. Polyphase Transposition Methods in General

a. In paragraph 33, brief mention was made of transposition systems in which two or more processes of rearrangement are involved. It was stated that only a very limited number of such transposition methods are practicable for military use, but that the degree of security afforded by them is considerably greater than that afforded by certain much more complicated substitution methods. The methods referred to are those which involve two or more successive transpositions, and merely for purposes of brevity in reference they will here be called *polyphase transposition methods* to distinguish them from the single monophase methods thus far described.

b. It is obvious that a polyphase transposition method may involve 2, 3, . . . successive transpositions of the letters of the plain text. To describe these methods in general terms, one may indicate that the letters resulting from a first transposition, designated as the T–1

REF ID:A56932

transposition, form the basis of a second, or T–2 transposition. If the process is continued, there may be T–3, T–4 . . . transpositions, and each may involve the use of a geometric figure or design. For convenience, the design involved in accomplishing the T–1 transposition may be designated as the D–1 design; that involved in accomplishing the T–2 transposition as the D–2 design, etc. However, it may as well be stated at this point, that so far as military cryptography is concerned, methods which involve more than D–2 and T–2 elements are entirely impractical and often those which involve no more than D–2 and T–2 elements are also impracticable for such use.

93. True and False Polyphase Transpositions

a. It is possible to perform two or more transpositions with the letters of a text and yet the final cryptogram will be no more difficult to solve than if only a single transposition had been effected. The equivalent of this in the case of substitution ciphers is to encipher a monoalphabetic cryptogram by means of a second single alphabet; the final result is still a monoalphabetic substitution cipher. Likewise, if a message had been enciphered by a simple form of route transposition and a second and similar or approximately similar form of simple route transposition is again applied to the text of the first transposition, the final text is still that of a monophase transposition cipher. Again, two transpositions may be accomplished without really affecting a more thorough scrambling of the letters composing the original text. Examples will serve to clarify the differences between false and true polyphase transposition.

b. Note the following simple columnar transposition cipher prepared according to the method described in paragraph *27*:

Message: DELIVER ALL AMMUNITION TO 4TH DIVISION DUMP

Keyword: SCHEDULE = S C H E D U L E / 7-1-5-3-2-8-6-4

Figure 38.

REF ID:A56932

In producing the foregoing cryptogram only the columns were transposed. Suppose that by prearrangement, using the keyword BREAK (derived numerical key = 2–5–3–1–4), the horizontal lines of the foregoing enciphering rectangle were also to be transposed. For example, let the horizontal lines of the rectangle D–1 be transposed immediately before taking the letters out of the columns of the design (in key-number order) to form the cipher text. Thus:

2	D	E	L	I	V	E	R	A
5	L	L	A	M	M	U	N	I
3	T	I	O	N	T	O	F	O
1	U	R	T	H	D	I	V	I
4	S	I	O	N	D	U	M	P

D–1

7	1	5	3	2	8	6	4
U	R	T	H	D	I	V	I
D	E	L	I	V	E	R	A
T	I	O	N	T	O	F	O
S	I	O	N	D	U	M	P
L	L	A	M	M	U	N	I

D–2

Cryptogram (T–2):

REIIL DVTDM HINNM IAOPI TLOOA VRFMN
UDTSL IEOUU

Figure 39.

c. The foregoing, however, is not a case of true polyphase or so-called *double* transposition. The same final result may be accomplished in a way which will at first glance appear quite different but is in reality one that accomplishes the same two operations by combining them in one operation. Let the message be inscribed as before, but this time with both numerical keys applied to the top and side of the rectangle. Then let another rectangle of the same dimensions, but with numbers in straight sequence instead of key-number sequence, be set alongside it. Thus:

	7	1	5	3	2	8	6	4
2	D	E	L	I	V	E	R	A
5	L	L	A	M	M	U	N	I
3	T	I	O	N	T	O	F	O
1	U	R	T	H	D	I	V	I
4	S	I	O	N	D	U	M	P

D–1

	1	2	3	4	5	6	7	8
1								
2								
3								
4								
5								

D–2

Figure 40.

Each letter D–1 is now transferred to that cell in D–2 which is indicated by the row and column indicators of the letter in D–1. For example, the first letter, D, of D–1, has the indicators 2–7 and it is placed in

REF ID:A56932

the 2–7 cell in D–2; the second letter of D–1, which is E, is placed in the 2–1 cell of D–2, and so on. The final result is as follows:

	7	1	5	3	2	8	6	4
2	D	E	L	I	V	E	R	A
5	L	L	A	M	M	U	N	I
3	T	I	O	N	T	O	F	O
1	U	R	T	H	D	I	V	I
4	S	I	O	N	D	U	M	P

D–1

	1	2	3	4	5	6	7	8
1	R	D	H	I	T	V	U	I
2	E	V	I	A	L	R	D	E
3	I	T	N	O	O	F	T	O
4	I	D	N	P	O	M	S	U
5	L	M	M	I	A	N	L	U

D–2

Figure 41.

It will be seen that if the columns of D–2 are now read downwards in straight order from left to right the final cryptogram is identical with that obtained in figure 39: REIIL DVTDM, etc.

d. The foregoing cipher, often called the Nihilist Cipher, is referred to in some of the older literature as a double transposition cipher because it involves a transposition of both columns and rows; and indeed as described in *b* above it seems to involve a double process. It is, however, not an example of true double transposition. When the mechanism of this cipher is compared with that now to be described, the great difference in the cryptographic security of the two methods will become apparent.

94. True Double Transposition

In the form of the false double transposition described above, it is only entire columns and entire rows that are transposed. The disarrangement of the letters is after all not very thorough. In true double transposition this is no longer the case, for here the letters of columns and rows become so thoroughly rearranged that the final text presents a complete scrambling almost as though the letters of the message had been tossed into a hat and then drawn out at random.

Section III. TRUE DOUBLE TRANSPOSITION

95. True Double Transposition of the Columnar Type

a. It is by what is apparently a simple modification of certain of the columnar methods already described that an exceedingly good true double transposition can be effected. Let a numerical key be derived from a keyword in the usual manner and let the message be written out under this key to form a rectangle in the usual manner for columnar transposition. The length of the message itself determines the exact dimensions of the rectangle thus formed, and whether or not it is completely or incompletely filled.

REF ID:A56932

b. In its most effective form the double transposition is based upon an incompletely filled rectangle; that is, one in which one or more cells in the last line remain unfilled. An example of the method now follows: Let the keyword be INTERNATIONAL; the message to be enciphered, as follows:

OUR ATTACK SLOWING UP IN FRONT OF HILL 1000 YARDS SOUTHEAST OF GOLDENVILLE STOP REQUEST PROMPT REENFORCEMENT.

Keyword: I N T E R N A T I O N A L
Derived numerical key: 4-7-12-3-11-8-1-13-5-10-9-2-6

4	7	12	3	11	8	1	13	5	10	9	2	6
O	U	R	A	T	T	A	C	K	S	L	O	W
I	N	G	U	P	I	N	F	R	O	N	T	O
F	H	I	L	L	O	N	E	T	H	O	U	S
A	N	D	Y	A	R	D	S	S	O	U	T	H
E	A	S	T	O	F	G	O	L	D	E	N	V
I	L	L	E	S	T	O	P	R	E	Q	U	E
S	T	P	R	O	M	P	T	R	E	E	N	F
O	R	C	E	M	E	N	T					

D-1

4	7	12	3	11	8	1	13	5	10	9	2	6
A	N	N	D	G	O	P	N	O	T	U	T	N
U	N											

D-2

Figure 42a.

REF ID:A56932

The first, or D–1, rectangle is inscribed in the usual manner of simple numerical key columnar transposition. It is shown as D–1 in the accompanying figure. *The letters of T–1 transposition* are then inscribed in the second, or D–2, rectangle *in the normal manner of writing,* that is, from left to right and from the top downwards. This is shown in D–2 of figure 42a for the first two columns of D–1 (in numerical key order) after transfer of their letters into D–2. The letters of the remaining columns of D–1 are transferred in the same manner into D–2, yielding the following rectangle:

4	7	12	3	11	8	1	13	5	10	9	2	6
A	N	N	D	G	O	P	N	O	T	U	T	N
U	N	A	U	L	Y	T	E	R	E	O	I	F
A	E	I	S	O	K	R	T	S	L	R	R	W
O	S	H	V	E	F	U	N	H	N	A	L	T
R	T	I	O	R	F	T	M	E	L	N	O	U
E	Q	E	S	O	H	O	D	E	E	T	P	L
A	O	S	O	M	R	G	I	D	S	L	P	C
C	F	E	S	O	P	T	T					

Figure 42b.

For the T–2 text the letters are transcribed from the D–2 rectangle, reading down the columns in key-number order, and grouping the letters in fives. The cryptogram is as follows:

PTRUT OGTTI RLOPP DUSVO SOSAU AOREA
CORSH EEDNF WTULC NNEST QOFOY KFFHR
PUORA NTLTE LNLES GLOER OMONA IHIES
ENETN MDIT

e. In paragraph 29 a variation of the simple columnar key method of transposition was described. If the process therein indicated is repeated, double transposition is effected. The following example will serve to illustrate the method, using the same message and key as were used in the paragraph 29:

Message: REQUEST IMMEDIATE REENFORCEMENTS

Keyword: P R O D U C T
Derived numerical key: 4–5–3–2–7–1–6

REF ID:A56932

Encipherment:

```
     4-5-3-2-7-1-6  4-5-3-2-7-1-6  4-5-3-2-7-1-6
Text: R E Q U E S T  I M M E D I A  T E R E E N F
T-1: S I N E U E E  E Q M R C R I  T O T E M E R
T-2: E R E E E R E  F N M T A S E  T S E I Q O T

     4-5-3-2-7-1-6  4-5
     O R C E M E N  T S
     S T A F N E D  E M
     M E I R D U C  M N
```

Cryptogram:

```
EREEE REFNM TASET SEIQO TMEIR
DUCMN
```

d. In some respects this modified method is simpler for the novice to perform correctly than is that employing rectangles. Experience has shown that many inexpert cryptographic clerks fail to perform the two transpositions correctly when D–1 and D–2 rectangles are employed in the work.

96. General Remarks on True Polyphase Transposition

a. The cryptographic security of the true double transposition method deserves discussion. Careful study of a cryptogram enciphered by the double transposition method set forth in paragraph 95 *b* and *c* will indicate that an extremely thorough scrambling of the letters is indeed brought about by the method. Basically, its principle is the splitting up of the adjacent or successive letters constituting the plain text by *two* sets of "cuts", the second of which is in a direction that is perpendicular to the first, with the individual "cuts" of both sets arranged in a variable and irregular order. It is well adapted for a regular and voluminous exchange of cryptograms between correspondents, because even if many messages in the same key are intercepted, *so long as no two messages are identical in length,* they can only be cryptanalyzed after considerable effort.

b. Triple and quadruple transpositions of the same nature are possible but not practical for serious usage. Theoretically, a continuation or repetition of the tranposition process will ultimately bring about a condition wherein the D–n rectangle is identical with the D–1 rectangle; in other words, after a certain number of transpositions the rectangle produced by a repetition of the *cryptographing* process results finally in *decryptographing* the message. Exactly how many repetitive transpositions intervene in such cases is extremely variable and depends upon factors lying outside the scope of this text.

REF ID:A56932

c. In the example of cryptographing given in paragraph 95*b*, the D–1 and D–2 rectangles are identical in dimensions, and identical numerical keys are applied to effect the T–1 and T–2 transpositions. It is obvious, however, that it is not necessary to maintain these identities; D–1 and D–2 rectangles of different dimensions may readily be employed, and even if it is agreed to have the dimensions identical, the numerical keys for the two transpositions may be different. Furthermore, it is possible to add other variable elements. (1) The direction or manner of inscribing the letters in the D–1 rectangle may be varied; (2) the direction of reading off or taking the letters out of the D–1 rectangle in effecting the T–1 transposition, that is, in transferring them into the D–2 rectangle, may be varied; (3) the direction of inscribing these letters in the D–2 rectangle may be varied; (4) the direction of reading off or taking the letters out of the D–2 rectangle in effecting the T–2 transposition may be varied.

d. The solution of cryptograms enciphered upon the double transposition principle is often made possible by the presence of certain plain-text combinations, such as QU and CH (in German). For this reason, careful cryptographers substitute a single letter for such combinations, as decided upon by preagreement. For example, in one case the letter Q was invariably used as a substitute for the compound CH, with good effect.

Section IV. GRILLES AND OTHER TYPES OF MATRICES

97. Type of Cryptographic Grilles

Broadly speaking, cryptographic grilles[2] are sheets of paper, cardboard, or thin metal in which perforations have been made for the uncovering of spaces in which letters (or groups of letters, syllables, entire words) may be written on another sheet of paper upon which the grille is superimposed. This latter sheet, usually made also of cross-section paper, will hereafter be designated for purposes of brevity in reference as the *grille grid,* or *grid.* Its external dimensions are the same as those of the grille. Grilles are of several types depending upon their construction and manner of employment. They will be treated here under the titles of (1) simple grilles, (2) revolving grilles, (3) nonperforated grilles, and (4) "post card" grilles.

98. Simple Grilles

a. These consist usually of a square in which holes or apertures have been cut in prearranged positions. When the grille is superimposed upon

[2] Also often called "stencils." The general term *matrix* (plural, *matrices*) is very useful in referring to a geometric figure or diagram used for transposition purposes. Other terms in common use are *cage, frame, box,* etc.

REF ID:A56932

the grid, these apertures disclose cells on the grid, in which cells letters, groups of letters, syllables, or entire words may be inscribed. An example is shown in figure 43. The four sides of the obverse surface of the grille are designated by the figures 1, 2, 3, 4; the four sides of the reverse surface, by the figures 5, 6, 7, 8. These figures are employed to indicate the position of the grille upon the grid in encipherment.

b. (1) In cryptographing a message the grille is placed upon the grid, in one of the eight possible positions: Obverse surface up, with figure 1, 2, 3, or 4 at the top left; or reverse surface up, with

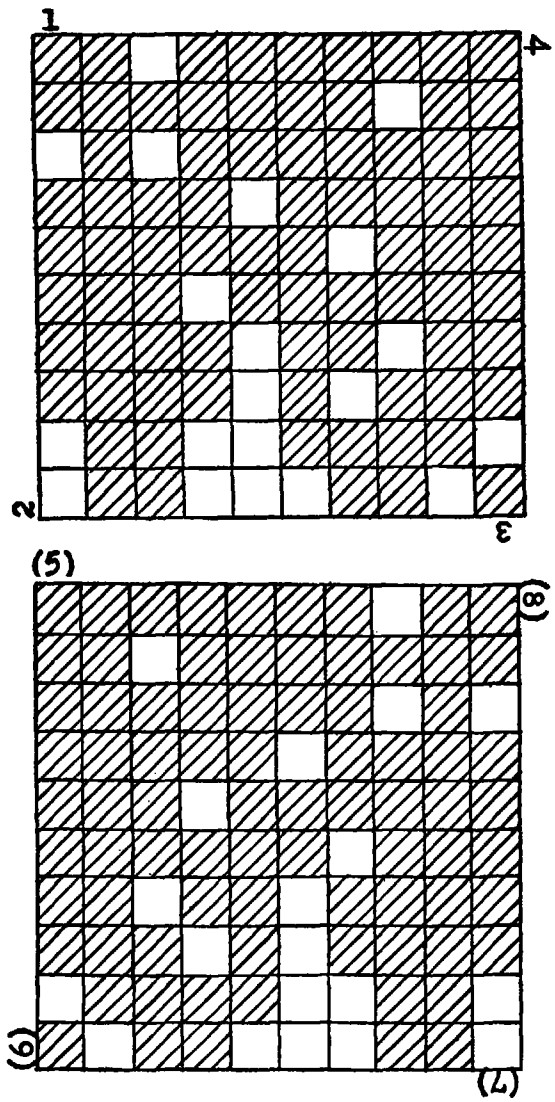

Figure 43.

REF ID:A56932

figure 5, 6, 7, or 8 at the top left. The letters of the plain text are then inscribed in the cells disclosed by the apertures, following any prearranged route. In figure 44, the normal manner of writing, from left to right, and from the top downwards, has been followed in the inscription, the message being ALL DESTROYERS OUTSIDE.

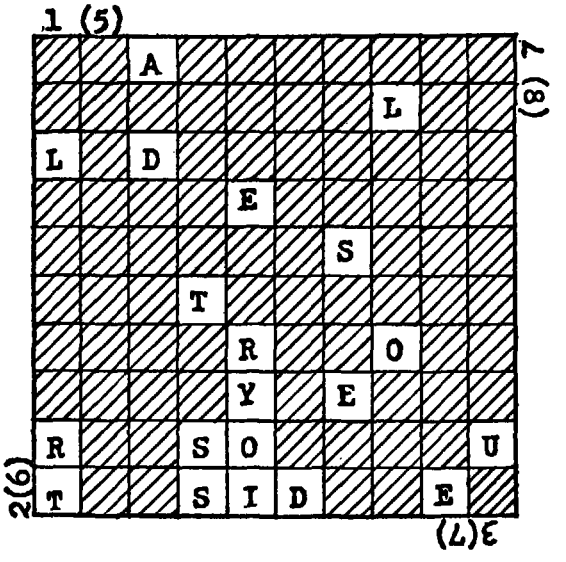

Figure 44.

(2) The transcription process now follows. The cipher text is written down, the letters being taken by following any prearranged route, which must be perpendicular to the route of inscription, otherwise the letters will follow in plain-text order. In the following, the route is by columns from left to right.

Cryptogram:

LRTAD TSSER YOIDS ELOEU

(3) If the number of letters of the plain-text message exceeds the number of cells disclosed by one placement of the grille, the letters given by this placement are written down (in cryptographic order), and then the grille is placed in the next position on a fresh grid; the process is continued in this manner until the entire message has been cryptographed. The several sections of the cipher letters resulting from the placements of the grille on successive grids merely follow each other in the final cryptogram. In this manner of employment it is only necessary for the correspondents to agree upon the initial position of the grille and its successive positions or placements.

REF ID:A56932

c. It is obvious that by the use of a simple grille the letters of a message to be cryptographed may be distributed within an enveloping message consisting mostly of "dummy" text, inserted for purposes of enabling the message to escape suppression in censorship. For example, suppose the grille shown in figure 43 is employed in position 1 and the message to be conveyed is ALL DESTROYERS OUTSIDE. The letters of this message are inscribed in their proper places on the grid, exactly as shown in figure 44. An "open" or disguising text is now to be composed; the latter serving as an envelope or "cover" for the letters of the secret text, which remain in the positions in which they fall on the grid. The open or disguising text, in other words, is built around or superimposed on the secret text. Note how this is done in figure 45, with an apparently innocent message reading:

I HAVE WORKED VERY WELL ALL DAY, TRYING TO GET EVERYTHING STRAIGHTENED UP BEFORE GOING ON MY NEXT TRIP SOUTH, BUT INSIDE TEN DAYS . . .

1 (5)

I	H	A	V	E	W	O	R	K	E	4 (8)
D	V	E	R	Y	W	E	L	L	A	
L	L	D	A	Y	T	R	Y	I	N	
G	T	O	G	E	T	E	V	E	R	
Y	T	H	I	N	G	S	T	R	A	
I	G	H	T	E	N	E	D	U	P	
B	E	F	O	R	E	G	O	I	N	
G	O	N	M	Y	N	E	X	T	T	
R	I	P	S	O	U	T	H	B	U	
T	I	N	S	I	D	E	T	E	N	

2 (6) 3 (7)

Figure 45.

d. The foregoing method naturally requires the transmission of considerably more text than is actually necessary for conveying the message intended. Where questions of censorship are not involved, the method is therefore impractical. A modification of the method suggests itself in the use of a transparent sheet of paper superimposed upon a square or other figure in which the individual cells are irregularly numbered and the inscription process follows the sequence of numbers. An example is shown in figure 46, using the message ROCK CREEK BRIDGE WILL BE DESTROYED WHEN TAIL HAS CROSSED.

b

Figure 46.

The transcription may now follow any prearranged route. The normal method of reading would produce the cryptogram beginning WCTEH OEERI, etc. It is obvious that the correspondents must possess designs with identically numbered cells.[3]

99. Revolving Grilles

a. In this type of grille (see fig. 47a) the apertures are also formed by perforating a sheet of cross-section paper according to prearrangement, but these apertures are so distributed that when the grille is turned four times successively through angles of 90° and set in four *grille positions* on the grid, all the cells on the grid are disclosed in turn. (The preparation of such grilles is discussed in par. 103.) If letters are inserted in the cells so disclosed, then after a complete revolution of the grille every one of the cells of the grid will contain a letter and thus the grid will be completely filled. For this reason such a grille is also called a *self-filling,* or an *automatic-completion* grille. The secrecy of messages enciphered by its means is dependent upon the distribution or position of the apertures, the sequence of grille positions on the grid, that is, whether in the order 1, 2, 3, 4 clockwise; or 1, 3, 4, 2 etc.), and the route followed in inscribing and transcribing the letters in the cells of the grid. For each position of the grille, one-fourth the total number of letters of the text is inscribed; hence it is convenient to refer to "sections" of the text, it being understood that each section consists of one-fourth the total number of letters.

b. There are two possible procedures so far as the inscription-transcription sequence is concerned. (1) The letters of the plain text may be inscribed in the cells of the grid through the apertures disclosed by the grille and then, when the grid has been completely filled, the grille removed, and the letters transcribed from the grid according to a prearranged route; or, (2) the letters of the plain text may first be inscribed in the cells of the grid according to a prearranged route and then the grille applied to the completely-filled grid to give the sequence of letters

[3] The system employed by the French Army in 1886 was of the nature here described.

ESEAT OIDTL YNOIN AHEAH
EDFOT NHSHH ETAMI YOSRE

Figure 47.

REF ID:A56932

forming the cipher text of the transcription process. The first method will be described in *c* below; the second in *e* below.

c. Taking the simplest manner of inscribing the letters, that is, from left to right and from the top downwards, the letters of the first section of the text are inscribed in the cells disclosed by the apertures, the grille being in the first position. This is shown in b of figure 47. The grille is then given ¼ turn clockwise, bringing figure 2 to the top left. If the grille has been correctly prepared, none of the cells disclosed in the second grille position on the grid will be occupied by a letter. The letters of the second section are then inscribed, this being shown in c of figure 47. In d and e of figure 47, the results of inscribing the third and fourth sections, respectively, are shown. The letters of the cryptogram are then taken out of the completed grid by following any prearranged route of transcription. The cryptogram below has been transcribed by following down the columns in succession from left to right.

d. To decryptograph such a message, the cipher letters are inscribed columnwise in a grid 10 by 10 (that is, one composed of 100 cells, 10 per side) and then the grille applied to the square in four consecutive positions corresponding to those used in cryptographing. The letters disclosed by each placement of the grille are written down as they appear, section after section.

e. The second manner of employing a revolving grille is merely the reciprocal of the first. The procedure followed in the first method to *decryptograph* a message is followed in the second method to *cryptograph* a message; and the procedure followed in the first method to cryptograph is followed in the second method to decryptograph.

100. Grilles of Other Geometric Forms

Grilles are not limited to square-shaped figures. They may be equilateral triangles, pentagons, hexagons, and so on. Any figure which can be pivoted upon a central point and which when revolved upon this pivot can be placed in a succession of homologous positions over a grid corresponding to the grille will serve equally well. A triangle affords three grille positions, a pentagon, five, and so on.

101. Polyphase Transposition by Grilles

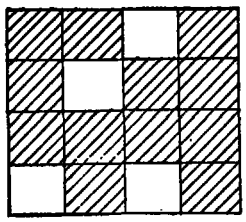
One grille may be employed to inscribe the letters of the message on the grid, and a second, and different, grille employed to transcribe them from the grid to form the final text of the cryptogram. This would constitute a real double transposition method of great complexity. Polyphase transposition by a series of grilles is of course possible.

REF ID:A56932

102. Increasing the Security of Revolving Grilles

a. The total number of letters which a grille will exactly encipher is termed its *capacity.* If the number of letters of a message is always equal to the total capacity of the grille, this information is of great aid in solution by the enemy. For example, a message of 64 letters indicates a grille 8 by 8 with 16 apertures; one of 144 letters, a grille 12 by 12 with 36 apertures, and so on. There are, however, methods of employing a grille so that it will serve to encipher messages the lengths of which are greater or less than the capacity of the grille.

b. When the total number of letters is less than the capacity of the grille, no modification in method of use is necessary. Encipherment of such a message comes to a close when the last plain-text letter has been inscribed. In decryptographing such a message, the recipient must strike out, on the grid upon which he is to inscribe the cipher text, a number of cells corresponding to the difference between the number of letters of the text as received and the total capacity of the grille. The location of the cells to be thus eliminated must be prearranged, and it is best usually to strike them off from the final positions of the grid.



a

15	29	1	30	19	33	5	
42	2	16	43	46	6	20	
17	44	31	18	21	47	34	
3	32	4	45	7	35	8	
25	38	11	39	22	36	9

27	52	40	28	24	49	37	
13	41	14					

b

Figure 48.

c. When the total number of letters is equal to or greater than the capacity of the grille, a grid of greater capacity than that of the grille can be prepared, on which the grille may be positioned several times, thus forming a large or composite grid composed by the juxtaposition of the several small grids. If there are a few cells in excess of the actual number required, these may be struck off from the large grid at prearranged points, for example, from the last column and row, as shown in b of figure 48. The grille is then placed in its first position in turn on each of the component grids, then in its second position, and so on. An example will serve to illustrate. A message of fifty-two letters is to be

REF ID:A56932

enciphered with the grille shown in a of figure 48, the capacity of which is sixteen letters. The number of letters of the message being greater than three times sixteen, the composite grid must be composed of four small grids containing a total of sixty-four cells. Therefore, twelve of these cells must be eliminated. These are shown in b of figure 48, together with the number indicating the positions occupied by the letters of the text.

103. Construction of Revolving Grilles

a. There are several ways of preparing revolving grilles, of which the one described below is the most simple. All methods make use of cross-section paper.

b. Suppose a revolving grille with a capacity of 100 letters is to be constructed. The cells of a sheet of cross-section paper 10 by 10 are numbered consecutively in *bands* from the outside to the center, in the manner shown in a of figure 49. It will be noted that in each band, if n is the number of cells forming one side of the band, the highest number assigned to the cells in each band is $n - 1$.

c. It will be noted that in each band there is a quadruplication of each digit; the figure 1 appears four times, the figure 2 appears four times, and so on. From each receding band there is to be cut out $(n-1)$ cells: from the outermost band, therefore, nine cells are to be cut out; from the next band, seven; from the next, five; from the next, three; and from the last, one cell. In determining specifically what cells are to be cut out in each band, the only rules to be observed are these: (1) One and only one cell bearing the figure 1 is to be cut out, one and only one cell bearing the figure 2 is to be cut out, and so on; (2) as random a selection as possible is to be made among the cells available for selection for perforation. In b of figure 49 is shown a sample grille prepared in this way.

d. If the side of the grille is composed of an odd number of cells, the innermost band will consist of but one cell. In such case this central cell must not be perforated.

e. It is obvious that millions of differently perforated grilles may be constructed. Grilles of fixed external dimensions may be designated by indicators, as was done by the German Army in 1915 when this system was employed. For example, the FRITZ grille might indicate a 10 by 10 grille, serving to encipher messages of about 100 letters; the ALBERT grille might indicate a 12 by 12 grille, serving to encipher messages of about 144 letters, and so on. Thus, with a set of grilles of various dimensions, all constructed by a central headquarters and distributed to lower units, systematic use of grilles for messages of varying lengths can be afforded.

f. A system for designating the positions of the perforated cells of a grille may be established between correspondents, so that the necessity

REF ID:A56932

for physical transmission of grilles for intercommunication is eliminated. An example of a possible system is that which is based upon the coordinate method of indicating the perforations. The columns from left to right and the rows from bottom to top are designated by the letters A, B, C, . . . Thus, the grille shown in b of figure 49 would have the following formula:

ADG; BBEH; CDJ; DEG; EACH; FFI; GE; HBDHJ; IDG; JABFI.

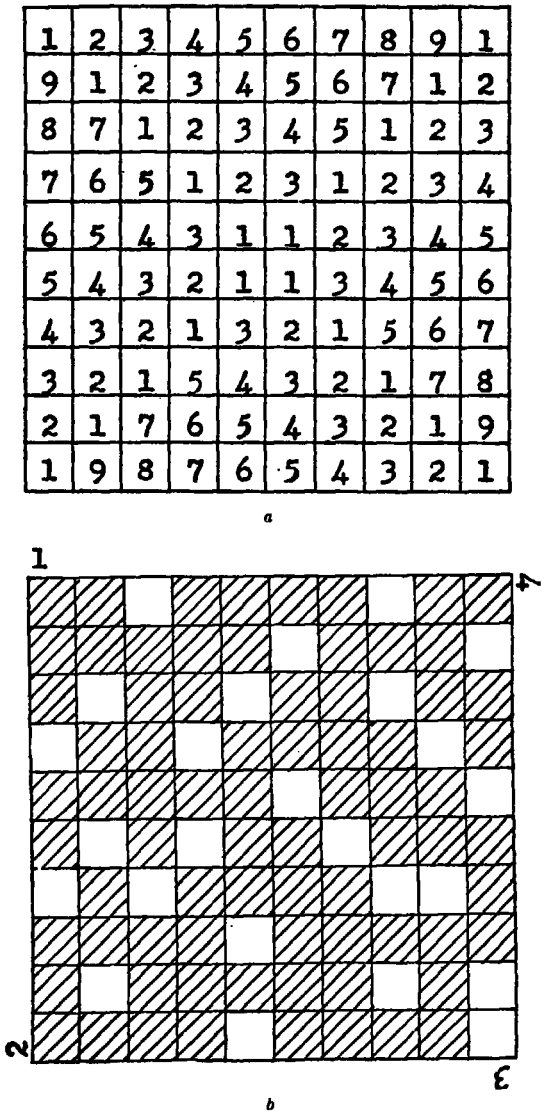

Figure 49.

REF ID:A56932

g. Given the formula, the eight corners of the grille can be labeled in various ways by prearrangement; but the simplest method is that shown in connection with b of figure 49. Then the initial position of the grille can be indicated by the number which appears at the upper left-hand corner when the grille is placed on the grid, ready for use. Thus, position 1 indicates that the grille is in position with the figure 1 at the upper left-hand corner; position 3, with the figure 3 at the upper left-hand corner, etc.

h. The direction of revolving the grille can be clockwise or counterclockwise, so that correspondents must make arrangements beforehand as to which direction is to be followed.

i. Revolving grilles can be constructed so that they have two operating faces, an obverse and a reverse face. They may be termed *revolving-reversible* grilles. The principles of their construction merely involve a modification of those described in connection with ordinary revolving grilles. A revolving-reversible grille will have eight possible placement indicators; usually positions 1 and 5, 2 and 6, and so forth, correspond in this obverse-reverse relationship, as shown in figure 43.

j. The principles of construction described above apply also to grilles of other shapes, such as triangles, pentagons, and so forth.

104. Nonperforated Grilles

a. All the effects of a grille with actual perforations may be obtained by the modified use of a nonperforated grille. Let the cells that would normally be cut out in a grille be indicated merely by crosses thereon, and then on a sheet of cross-section paper let the distribution of letters resulting from each placement of the grille on a grid be indicated by inserting crosses in the appropriate cells, as shown in figure 50.

Grille Grille Position

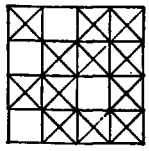

Figure 50a.

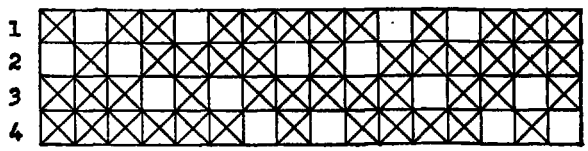

Figure 50b.

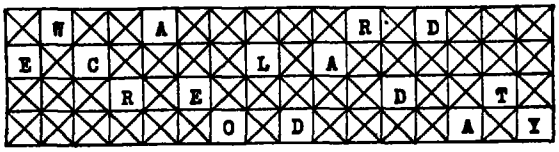
b. Note should be made of the fact that in figure 50b the distribution of crosses shown in the third row of cells is the reverse of that shown in the first; the distribution shown in the fourth row is the reverse of that shown in the second. This rule is applicable to all revolving grilles and is of importance in solution.

c. If the letters of the text are now inscribed (normal manner of writing) in the cells not eliminated by crosses, and the letters transcribed

REF ID:A56932

from *columns* to form the cryptogram, the results are the same as though a perforated grille had been employed. Thus:



Cryptogram:

EWCRA EOLDA RDDAT Y

Figure 50c.

d. It is obvious that a numerical key may be applied to effect a columnar transposition in the foregoing method, giving additional security.

e. The method is applicable to grilles of other shapes, such as triangles, pentagons, hexagons, octagons, etc.

f. In figure 50c it is noted that there are many cells that might be occupied by letters but are not. It is obvious that these may be filled with nulls so that the grid is completely filled with letters. Long messages may be enciphered by the superposition of several diagrams of the same dimensions as figure 50c.

105. Rectangular or "Post Card" Grilles

a. The grille shown in figure 51 differs from the ordinary revolving grille in that (1) the apertures are rectangular in shape, and are greater in width, thus permitting of inscribing several letters in the cells disclosed on the grid by each perforation of the grille; and (2) the grille itself admits of but two positions with its obverse side up and two with its reverse side up. In figure 51 the apertures are numbered in succession from top to bottom in four series, each applying to one position of the grille; the numbers in parentheses apply to the apertures when the grille is reversed; the numbers at the corners apply to the four positions in which the grille may be placed upon the grid.

b. One of the ways in which such a grille may be used is to write the first letter of the text at the extreme left of the cell disclosed by aperture 1, the second letter, at the extreme left of the cell disclosed by aperture 2, and so on. The grille is retained in the same position and the 17th letter is written immediately to the right of the 1st, the 18th immediately to the right of the 2d, and so on. Depending upon the width of the aperture, and thus of the cells disclosed on the grid, 2, 3, 4 . . . letters may be inserted in these cells. When all the cells have been filled, the grille may then be placed in the second position, then the third, and finally, the fourth.

REF ID:A56932

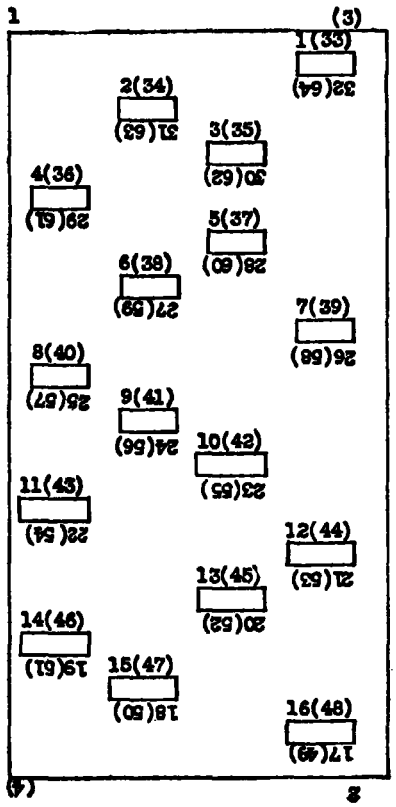


Figure 51.

c. Another way in which the grille may be used is to change the position of the grille after the 16th letter has been inserted, then after the 32d, 48th, and 64th; the 65th letter is then inserted to the right of the 1st, the 81st, to the right of the 17th, and so on until the grid is completed.

d. Whole words may, of course, be inserted in the cells disclosed by the apertures, instead of individual letters, but the security of the latter method is much lower than that of the former.

e. The text of the grid may be transcribed (to form the cryptogram) by following any prearranged route.

f. The successive positions of a post card grille may be prearranged. The order 1, 2, 3, 4 is but one of 24 different sequences in which it may be superimposed upon the grid.

g. A modification of the principles set forth in paragraph 103, dealing with the construction of revolving grilles, is applied in the construction of rectangular or "post card" grilles. Note the manner in which the cells in a of figure 51 are assigned numbers; homologous cells in each band receive the same number. In a of figure 52 there are three bands,

REF ID:A56932

numbered from 1 to 8, 9 to 16, and 17 to 24. Then in each band one and only one cell of the same numbered set of four cells is cut out. For example, if cell 1a is selected for perforation from band 1 (as indicated by the check mark in that cell), then a cross is written in the other three homologous cells, 1b, c, and d, to indicate that they are not available for selection for perforation. Then a cell bearing the number 2 in band 1 is selected, for example, 2c, and at once 2a, b, and d are crossed off as being ineligible for selection, and so on. In c of figure 52 is shown a grille as finally prepared, the nonshaded cells representing apertures.

h. The grille, c of figure 52, is a "six-column" one, that is, the cells form six columns. It is obvious that grilles with any even number of columns of cells are possible. The number of apertures in each band should be equal and this number multiplied by the number of bands and then by 4 should equal the capacity of the grille. In the case of the one shown in c of figure 52, the capacity is 8 by 3 by 4 or 96 cells; this is the same as is obtained merely by multiplying the height (in cells) by the

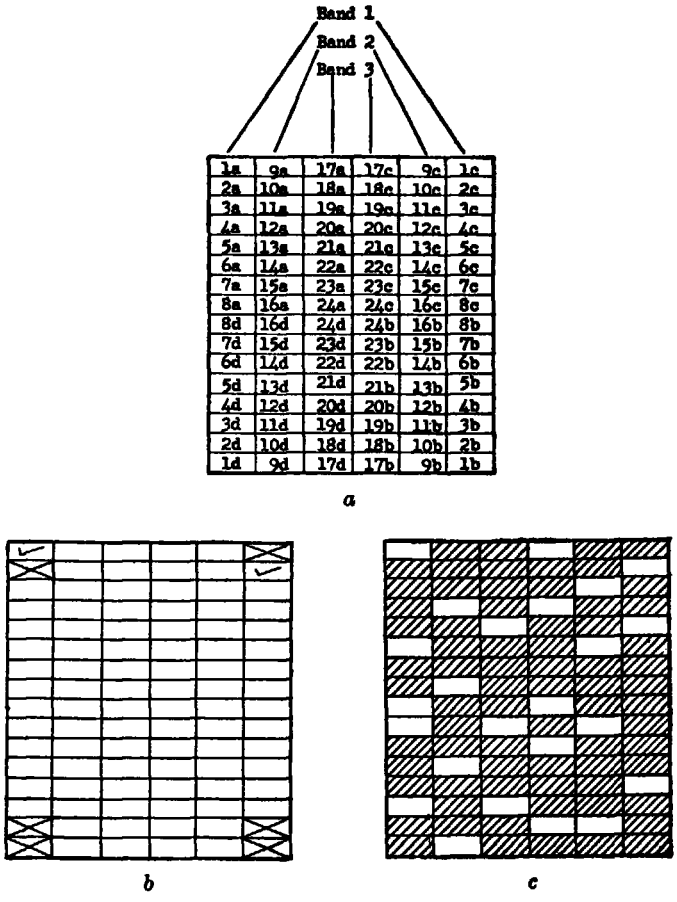

Figure 52.

REF ID:A56932

number of columns, $16 \times 6 = 96$. If four letters are inscribed in each rectangle, the capacity of the grille in terms of letters is 384. The grid in this case would, after completion, present 24 columns of letters, to which a numerical key for a second transposition can be applied in transcription to produce the final text of the cryptogram.

106. Indefinite or Continuous Grilles

a. In his *Manual of Cryptography,* Sacco illustrates a type of grille which he has devised and which has elements of practical importance. An example of such a grille is shown in figure 53. This grille contains 20 columns of cells, and each column contains 5 apertures distributed at random in the column. There are therefore 100 apertures in all, and this is the maximum number of letters which may be enciphered in one position of the grille. The plain text is inscribed vertically, from left to right, using only as many columns as may be necessary to inscribe the complete message. A 25-letter message would require but 5 columns. To form the cryptogram the letters are transcribed *horizontally* from the rows, taking the letters from left to right as they appear in the apertures. If the total number of letters is not a multiple of 5, sufficient nulls are added to make it so. In decryptographing, the total number of letters is divided by 5, this giving the number of columns employed. The cipher text is inscribed from left to right and top downwards in the apertures in the rows of the indicated number of columns and the plain text then reappears in the apertures in the columns, reading downward and from left to right. (It is, of course, not essential that nulls be added in the encipherment to make the length of the cryptogram an exact multiple of 5, for the matter can readily be handled even if this is not done. In decipherment the total number of letters divided by 5 will give the number of complete columns; the remainder left over from the division will give the number of cells occupied by letters in the last column on the right.)

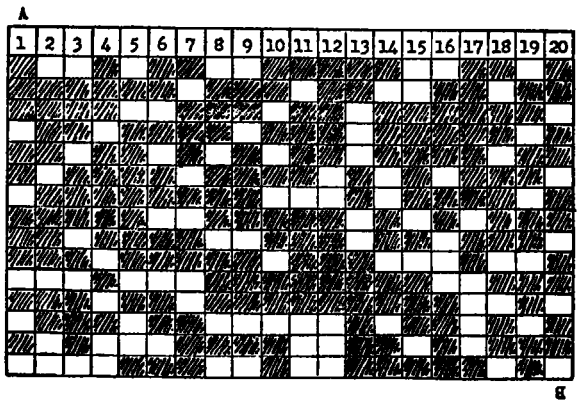

Figure 53a.

REF ID:A56932

b. Such a grille can assume 4 positions, two obverse and two reverse. Arrangements must be made in advance as to the sequence in which the various positions will be employed. That is why the grille shown in figure 53a has the position-designating letter "A" in the upper left-hand corner and the letter "B" (upside down) in the lower right-hand corner. On the obverse side of the grille would be the position-designating letters "C" and "D."

c. Figure 53b shows how a message is enciphered.

Message:

AM RECEIVING HEAVY MACHINE GUN FIRE FROM HILL SIX TWO ZERO.

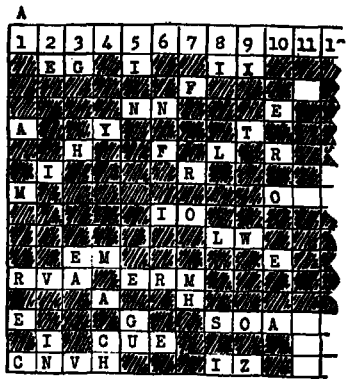

Figure 53b.

Cryptogram:

EGIIX FNNEA YTHFL RIRMO IOLWE MERVA ERMAH EGSOA ICUEC NVHIZ.

(The letters E and A in the 10th column are nulls. Columns 11 to 20 are not used at all, the irregular right-hand edge of the grille merely indicating that this portion of the grille remains vacant.)

Section V. MISCELLANEOUS TRANSPOSITION SYSTEMS

107. Complex Route Transposition

a. In figure 54 a route for inscribing letters within a rectangle is indicated by a sequence of numbers. The initial point may be at any of the four corners of the rectangle, or it may be at any other point, as prearranged. The letters may be inscribed to form the rectangle by following the route indicated and then transcribed from the rectangle to form the cryptogram by following another route; or the letters may be inscribed according to one route and transcribed accordingly to the numerical route indicated.

b. A variation of the foregoing is that illustrated in figure 55, wherein the inscription follows the route shown by the arrows. The initial point

REF ID:A56932

of inscription is indicated by the figure 1, and the final point, by the figure 2.

c. In the foregoing case, the route is a succession of the moves made by the king in the game of chess; it forms the so-called "king's tour", in which the playing piece makes a complete or reentrant journey covering all cells of the chessboard, each cell being traversed only once. A route composed of a succession of moves made by the knight, or the so-called "knight's tour", is also possible, but in order to be practical a grid with the cells numbered in succession would have to be prepared for the correspondents, since millions of different reentrant knight's tours can be constructed[4] on a chessboard of the usual 64 cells.

90	61	60	31	30	1
2	29	32	59	62	89
88	63	58	33	28	3
4	27	34	57	64	87

8	23	38	53	68	83
82	69	52	39	22	9
10	21	40	51	70	81
80	71	50	41	20	11
12	19	42	49	72	79
78	73	48	43	18	13
14	17	44	47	74	77
76	75	46	45	16	15

Figure 54.

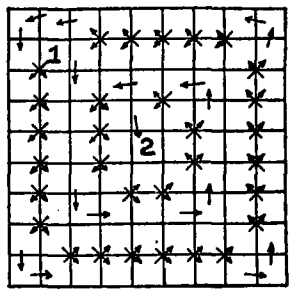

Figure 55.

108. Transposition of Groups of Letters, Syllables, and Words

There is nothing in the previously described methods which precludes the possibility of their application to pairs of letters, sets of three or more letters, or even syllables and whole words. Nor, of course, is their use limited to operations with plain text they may be applied as secondary steps after a substitutive process has been completed (see sec. I, ch. 10).

109. Disguised Transposition Methods

a. The system often encountered in romances and mystery stories, wherein the message to be conveyed is inserted in a series of nonsignificant words constructed with the purpose of avoiding or evading suspicion, is a species of this form of "open" cryptogram involving transposition. The "open" or enveloping, apparently innocent text may be designated as the *external text;* the secret or cryptographic text may be designated as the *internal text.* A complicated example of external or open and internal or secret text is that shown in paragraph 98.

[4] See Ball, W. W. R., Mathematical Recreations and Essays, London, 1928.

REF ID:A56932

b. Little need be said of the method based upon constructing external text the letters of which, at prearranged positions or intervals, spell out the internal text. For example, it may be prearranged that every fourth letter of the external text forms the series of letters for spelling out the internal text, so that only the 4th, 8th, 12th . . . letters of the external text are significant. The same rule may apply to the complete words of the external text, the *n*, *2n*, *3n*, . . . words form the internal text. The preparation of the external text in a suitable form to escape suspicion *is not so easy as might be imagined,* when efficient, experienced, and vigilant censorship is at work. Often the paragraph or passage containing the secret text is sandwiched in between other paragraphs added to pad the letter as a whole with text suitable to form introductory and closing matter to help allay suspicion as to the presence of secret, hidden text.

c. A modification of the foregoing method is that in which the 1st, 3d, 5th, . . . words of a secret message are transmitted at one time or by one agency of communication, and the 2d, 4th, 6th, . . . words of the message are transmitted at another time or by another agency of communication. Numerous variations of this scheme will suggest themselves, but they are not to be considered seriously as practical methods of secret intercommunication.

d. Two correspondents may agree upon a specific size of paper and a special diagram drawn upon this sheet, the lines of which pass through the words or letters of the internal text as they appear in the external text. For example, the legs of an equilateral triangle drawn upon the sheet of paper can serve for this purpose. This method is practicable only when messages can be physically conveyed by messenger, by the postal service, or by telephotographic means. Many variations of this basic scheme may perhaps be encountered in censorship work.

110. Cipher Machines for Effecting Transposition

These may be dismissed with the brief statement that if any exist today they are practically unknown. A few words are devoted to the subject in paragraph 147.

REF ID:A56932

CHAPTER 9
SUBSTITUTION SYSTEMS

Section I. POLYGRAPHIC SYSTEMS

111. General

a. It will be recalled that chapter 3 dealt with the various types of cipher alphabets, simple monoalphabetic substitution, monoalphabetic substitution with variants, the more simple varieties of polyalphabetic substitution, cipher disks, and cipher tables. The following material on substitution is a continuation of the former, a thorough understanding of which is a requisite to the examination of the more complex types of substitution now to be set forth.

b. First it will be advisable to explain several terms which will be used. Substitution methods in general may be described as being *monoliteral* or *polyliteral* in character. In the former there is a strict letter-for-letter replacement, or, to include numerical and symbol methods, there is a "one-to-one" correspondence between the length of the units of the plain text and those of the cipher text, no matter whether the substitution is monoalphabetic or polyalphabetic in character. In polyliteral methods, however, this "one-to-one" correspondence no longer holds. A combination of two letters, or of two figures, or of a letter and a figure, may represent a single letter of the plain text; there is here a "two-to-one" correspondence, two characters of the cipher text representing one of the plain text. The methods described in chapter 3, fall under the latter designation; the cipher equivalents there shown are, properly speaking, bipartite in character. Tripartite cipher equivalents are also encountered. Polyliteral methods, therefore, are said to employ *polypartite alphabets,* of which the bipartite type is by far the most common. Further on in this text, polyliteral methods of greater complexity than those illustrated in chapter 3 will be discussed. Attention now will be directed more particularly to a different type of substitution designated as *monographic* and *polygraphic* substitution.

112. Monographic and Polygraphic Substitution

a. All the methods of substitution heretofore described are monographing in nature, that is, in the enciphering process the individual units subjected to treatment are single letters; there is a letter-for-letter substitution, or, to include numerical and symbol methods, there is, as in the

REF ID:A56932

ENTIAL

case of monoliteral substitution, a "one-to-one" correspondence between units of the plain text and those of the cipher text. In polygraphic substitution, however, *combinations* of letters of the plain text, considered as indivisible compounds, constitute the units for treatment in encipherment. If the units consist of pairs of plain-text letters, the encipherment is pair-for-pair, and is said to be *digraphic* in character; if the units consist of sets of three letters, it is *trigraphic* in character, and so on. There is still a "one-to-one" correspondence involved, but the units in these cases are composite in character and the individual elements composing the units affect the cipher equivalents *jointly*, rather than separately. The basic important factor in true polygraphic substitution is that *all* the letters of the group participate in the determination of the cipher equivalent of the group; the identity of *each* letter of the plain-text group affects the composition of the *whole* cipher group. Thus, in a certain digraphic system AB_p may be enciphered as XP_c, and AC_p, on the other hand, may be enciphered as NK_c; a difference in the identity of but one of the letters of the plain-text pair here produces a difference in the identity of *both* letters of the cipher pair.

b. For practical usage polygraphic substitution is limited to the handling of digraphs and trigraphs, although very occasionally groups of more than three letters may be employed for special purposes.

c. The fundamental purpose of polygraphic substitution is the suppression or rather the elimination of the frequency characteristics of ordinary plain text. It is these frequency characteristics which lead, sooner or later, to the solution of practically all substitution ciphers. When the substitution involves only individual letters in a monoalphabetic system, the cryptogram can be solved very quickly; when it involves individual letters in a polyalphabetic system, the cryptogram can usually be solved, but only after a much longer time and much more study, depending upon the complexity of the method. The basic principle in the solution, however, is to reduce the polyalphabetic text to the terms of monoalphabetic ciphers and then to solve the latter. In true polygraphic substitution on the other hand, the solution does not rest upon the latter basis at all because it is not a question of breaking up a complex text into simpler elements; it rests, as a rule, upon the possibility of analysis on the basis of the frequency of the polygraphic units concerned. If the substitution is digraphic, then the units are pairs of letters and the normal frequencies of plain-text pairs become of first consideration; if the substitution is trigraphic, the units are sets of three letters and the normal frequencies of plain-text trigraphs are involved. In the last two cases the data that can be employed in the solution are meager, and are far from definite or unvarying in their significance, and that is why solution of polygraphic substitution ciphers is often extremely difficult.

d. Just as in typography, when certain combinations of letters, such as fi, fl, and ffi, are mounted on one and the same piece of type, they are

REF ID:A56932

called logotypes or ligatures, so in cryptography, when combinations of two or more letters are to be treated as a unit in a cryptographic process, they may also be called ligatures and can be conveniently indicated as being so by placing a bar across the top of the combination. Thus, $\overline{CO}_p$ represents the digraph CO of the plain text. It will also be convenient to use the Greek letter θ to represent a letter of the alphabet, without indicating its identity. Thus, instead of the circumlocution "any letter of the plain text", the symbol θ_p will be used; and for the expression "any letter of the cipher text", the symbol θ_c will be used. The symbol $\overline{\theta\theta}_p$ then means "any plain-text digraph"; the symbol $\overline{\theta\theta}_c$ "any cipher-text digraph." To refer specifically to the 1st, 2d, 3d . . . member of a ligature, the exponent 1, 2, 3 . . . will be used. Thus, $\theta^2{}_p$ of $\overline{REM}_p$ is the letter E; $\theta^3{}_c$ of $\overline{XRZ}_c$ is Z.

TABLE I

(Showing only a partially filled table)

Initial letter ($\theta^1{}_p$) \ Final Letter ($\theta^2{}_p$)	A	B	C	D	E	F	G	H	I	J	K	. . .	X	Y	Z

	A	B	C	D	E	F	G	H	I	J	K		X	Y	Z	

113. Polygraphic Substitution by Means of Tables

a. The most simple method of effecting polygraphic substitution involves the use of tables similar to that shown in table I. This table merely presents equivalents for digraphs and is to be employed upon the coordinate system, $\theta^1{}_p$ of $\overline{\theta^1\theta^2}_p$ being sought in the column at the left or right, $\theta^2{}_p$ in the row at the top or bottom. The cipher pair, $\overline{\theta^1\theta^2}_c$, is

REF ID:A56932

then found at the intersection of the row and column thus indicated. For example, $\overline{AF}_p = \overline{YG}_c$; $\overline{FH}_p = \overline{AZ}_c$, etc.

b. Table I is reciprocal in nature; that is, $\overline{AF}_p = \overline{YG}_c$ and $\overline{YG}_p = \overline{AF}_c$. Thus, a single table serves for enciphering as well as for deciphering. The word DEFEND would be enciphered as YA NZ CY, and then grouped in fives: YANZC Y . . . . When a final single letter occurs, a null is added in order to make a pair of letters capable of being enciphered by the method. Reciprocity is, however, not an essential factor and for greater security nonreciprocal tables are more advisable. In such cases an enciphering table must have its complementary deciphering table.

c. Until the amount of text enciphered by means of such a table becomes great enough to disclose the cipher equivalents of the most frequently used digraphs, such as EN, ER, RE, TH, ON, etc., cryptograms based upon the table are relatively secure against solution.

d. A simple method for preventing the establishment of the frequencies characterizing these commonly used digraphs and thus eliminating the principal basis for their identification is given in paragraph 134*e*.

e. The factor that contributes most to the relatively high degree of security of the digraphic method described in *a* and *b* above is the absence of symmetry in the table employed; for this table is constructed by random assignment of values and shows no symmetry whatsoever in its arrangement of contents. Hence, even if θ^1_p in a first case of $\overline{\theta^1\theta^2}_p = \overline{\theta^1\theta^2}_c$ is identical with θ^1_p in a second case, $\overline{\theta^1\theta^2}_c$ in the first case is wholly different from $\overline{\theta^1\theta^2}_c$ in the second case. For example, table I shows that $\overline{AC}_p = \overline{XE}_c$ and $\overline{AD}_p = \overline{YY}_c$; the cipher resultants fail to give any hint that the plain-text pairs contain an identical letter.

f. If, however, the latter is not the case and the table exhibits symmetry in its arrangement of contents, solution is somewhat facilitated. Note table II, for example, in which two mixed sequences are employed to form the cipher equivalents. One mixed sequence is based upon the keyphrase WESTINGHOUSE AIR BRAKE; the other, upon the keyphrase GENERAL ELECTRIC COMPANY. The word FIRE would be enciphered as KIQA.

g. A cursory examination of table II shows that when θ^2_p is identical in two cases then θ^2_c is identical in these cases, so that in reality the encipherment is by no means truly digraphic in character. Described in cryptographic terms, the encipherment of θ^1_p is polyalphabetic in character whereas that of θ^2_p is monoalphabetic. A more obvious picture of this condition is brought out in the rearrangement of table II.

h. By a slight modification in arrangement but with no change in basic principle, the encipherment can be made monoalphabetic so far as θ^1_p is concerned, and polyalphabetic so far as θ^2_p is concerned. Note table IV.

i. The results given by table III or table IV may be duplicated by using sliding alphabets, as shown in figures 56 and 57. In the former, which corresponds to table III, alphabets I and IV are fixed, II and III are mounted upon the same strip, which is movable. To use these alphabets in encipherment, θ^1_p of $\overline{\theta^1\theta^2}_p$ is located on alphabet II and alphabets II–III are shifted so that θ^1_p is beneath A on alphabet I; θ^2_p is now sought in alphabet I and $\overline{\theta^1\theta^2}_c$ will be found under it on alphabets III and IV, respectively. Thus, for the word FIRE the successive positions of the alphabet strips are as shown below, yielding the cipher resultant KIQA.

$\overline{FI}_p = \overline{KI}_c$

k. Neither table III nor table IV presents the possibilities such tables might afford for digraphic substitution. They may, however, be rearranged so as to give results that will approach more closely to the desired ideal as to nonrelationship between cipher equivalents of plain-text pairs having an identical letter in common. Note that in table V, which is based upon the same primary alphabets as table III and table IV, the cipher equivalents are the same as in the latter tables, but they have been so distributed as to eliminate the undesirable and externally obvious relationship referred to. (In any table of this nature there can be only 676 different pairs of equivalents, since the table presents merely the permutations of the 26 letters taken two at a time. It is the distribution of the pairs which is important.)

l. Table V still shows symmetry in its construction, and a suspicion of its existence formed during the preliminary stages of cryptanalysis would aid materially in hastening final solution.

m. The foregoing tables have all been digraphic in nature, but a kind of false trigraphic substitution may also be accomplished by means of such tables, as illustrated in the accompanying table VI, which is the same as table V with the addition of one more alphabet at the top of the table.

n. In using this table, θ^1_p is located in alphabet I, and its equivalent, θ^1_c, taken from alphabet II; θ^2_p is located in alphabet III, and its equivalent, θ^2_c, taken from alphabet IV; θ^3_c is the letter lying at the intersection of the row indicated by θ^3_p in alphabet I and the column determined by θ^2_p. Thus, FIRE LINES would be enciphered NNZ IEQ KOV. It is obvious, however, that only the encipherment of θ^3_p is polyalphabetic in character; θ^1_p and θ^2_p are enciphered purely monoalphabetically. Various other agreements may be made with respect to the alphabets in which the plain-text letter will be sought in such a table, but the basic cryptographic principles are the same as in the case described.

o. Digraphic tables employing numerical equivalents instead of letter equivalents are, of course, possible but in this case the number of equivalents required, 676, means that combinations of three figures must be used.

Section II. MATRIX[5] DIGRAPHIC SUBSTITUTION

114. Disadvantages of Large Tables

Digraphic substitution by means of tables such as those illustrated in tables I, II, and V is impractical for military use because of the relatively large size that the table takes, and the inconvenience in their production, change, distribution, and handling. Just as it has been noted in section VI, chapter 3, that simple sliding alphabet strips can replace large quadricular tables, so it will be found that small matrices similar to a checkerboard can replace the large quadricular tables in digraphic substitution.

115. Four-Alphabet Matrix

a. The simple or single-alphabet matrix consists of a square 5 by 5, containing 25 cells in which the letters of a 25-element alphabet (I and J

[5] The word *matrix* as herein employed refers to "checkerboard" diagrams smaller than the quadricular tables illustrated in section I. These matrices usually comprise sections of 25 cells each.

REF ID:A56932

being interchangeable) are inserted in any prearranged order. When four such matrix alphabets are arranged in a large square as shown in figure 58, the latter may be employed for digraphic substitution to yield the same cipher results as does the much larger table I. In this square, θ^1_p of $\overline{\theta\theta}_p$ is sought in section 1; θ^2_p, in section 2. Thus, θ^1_p and θ^2_p will always form the northwest-southeast corners of an imaginary rectangle delimited by these two letters as located in these two sections of the square. Then θ^1_c and θ^2_c are, respectively, the letters at the northeast-southwest corners of this same rectangle. Thus, $\overline{TG}_p = \overline{TK}_c$; $\overline{WD}_p = \overline{TX}_c$; $\overline{OR}_p = \overline{PS}_c$; $\overline{UR}_p = \overline{WP}_c$, etc. In decryptographing, θ^1_c and θ^2_c are sought in sections 3 and 4, respectively, and their equivalents, θ^1_p and θ^2_p, noted in sections 1 and 2, respectively. It may, of course, be prearranged that θ^1_p should be sought in the section now labeled 3, θ^2_p, in that labeled 4, whereupon θ^1_c would be located in the section now labeled 1, θ^2_c, in that now labeled 2.

Sec. 3 (θ^1_c) — Sec. 2 (θ^2_p)

Figure 58.

b. It is possible to construct a digraphic substitution matrix that shows reciprocity in its $\overline{\theta\theta}_p = \overline{\theta\theta}_c$ relationship so that if $\overline{AB}_p = \overline{XY}_c$, for example, then $\overline{XY}_p = \overline{AB}_c$. Two conditions are essential to assure reciprocity. These are taken into consideration in the establishment of the $\overline{\theta^1\theta^2}_c$, or deciphering sections, and an example will serve to explain the process.

c. Two enciphering alphabets are first constructed; one in section 1 for θ^1_p, the other in section 2 for θ^2_p, as shown in figure 59a. The alphabet in section 3 is now to be constructed. Any horizontal row of section 1 is taken, for example, the row labeled 1, consisting of the letters BWGRM, and these letters are written on any horizontal row of section

3, in any transposed order, which is immediately written at the top of section 3, as shown in figure 59b.

Row 1 of section 1 was inserted in row 4 of section 3. The reciprocal permutation of 1 4 is 4 1, and therefore row 4 of section 1 must now be inserted in row 1 of section 3, and in the transposed order 5–2–4–1–3, as indicated at the top of section 3. The result is shown in figure 59c. Then

Figure 59d.

row 2 of section 1 is transferred to another row of section 3, for example, the fifth, and the letters inserted in the already indicated transposed order. Immediately thereafter, in order to continue the reciprocal permutation relationship, row 5 of section 1 becomes row 2 of section 3. This leaves row 3 of section 1 to become also row 3 of section 3, and to be reciprocal to itself. The result is shown in figure 59d, where section 3 is

REF ID:A56932

completely constructed. The foregoing principle of permutation reciprocity applies equally to the rows of section 4. Suppose the permutation 3–5–1–4–2 is decided upon for the rows of section 4. This means that rows 1 and 3 of section 2 become rows 3 and 1 of section 4; rows 2 and 5 of section 2 become 5 and 2 of section 4; row 4 of section 2 becomes row 4 of section 4. As regards the transposed order within the rows of section 4, the following rule applies: The letters forming a complete column from the top of section 3 to the bottom of section 2, whatever their order, must also form a complete column from the top of section 1 to the bottom of section 4. For example, the column designated by the number 5 of section 3 contains the letters OHKMECOSGT; column 5 of section 1 contains five of these letters, MEKOH; therefore, the completed column must contain the letters, COSGT but in the transposed order given by the permutation selected for the rows of section 4, namely, 3–5–1–4–2.

The completed matrix is then as shown in figure 59e, and exhibits reciprocity throughout. Example: $\overline{BB}_p = \overline{LW}_c$, and $\overline{LW}_p = \overline{BB}_c$.

d. The total number of reciprocal permutations of five elements is 25, as follows:

Base 12345

(1) 12354	(6) 14325	(11) 21354	(16) 34125	(21) 45312
(2) 12435	(7) 14523	(12) 21435	(17) 35142	(22) 52341
(3) 12543	(8) 15342	(13) 21543	(18) 42315	(23) 52431
(4) 13245	(9) 15432	(14) 32145	(19) 43215	(24) 53241
(5) 13254	(10) 21345	(15) 32154	(20) 42513	(25) 54321

REF ID:A56932

Since the row permutations of sections 2 and 4 are independent, the total number of different four-alphabet matrices as regards row permutations is $25^2 = 625$. Taking into account the column permutations, $5 \times 4 \times 3 \times 2 \times 1$ in number, it is therefore possible to have 625×120 or 75,000 different, four-alphabet matrices of this nature, based upon the same two alphabets in sections 1 and 3. With changes in the latter, the number, of course, becomes very much greater.

116. Two-Alphabet Matrices

a. It is possible to effect digraphic substitution with a matrix consisting of but two sections by a modification in the method of finding equivalents. In the checkerboard shown in figure 60, $\theta^1{}_p$ of $\overline{\theta^1\theta^2}_p$ is located in the square at the left, $\theta^2{}_p$, in the square at the right.

	M	A	N	U	F	A	U	T	O	M	
	C	T	R	I	G	B	I	L	E	S	
$\theta^1{}_p\theta^2{}_c$	B	D	E	H	K	C	D	F	G	H	$\theta^2{}_p\theta^1{}_c$
	L	O	P	Q	S	K	N	P	Q	R	
	V	W	X	Y	Z	V	W	X	Y	Z	

Figure 60.

When $\overline{\theta^1{}_p\theta^2{}_p}$ are at the opposite ends of the diagonal of the imaginary rectangle defined by the letters, $\overline{\theta^1\theta^2}_c$ are at the opposite ends of the other diagonal of the same rectangle, just as in the preceding case. For example, $\overline{AL}_p = \overline{TT}_c$; $\overline{DO}_p = \overline{GA}_c$; $\overline{AT}_p = \overline{TA}_c$; $\overline{EH}_p = \overline{HE}_c$.

b. Reciprocity may be imparted to the two-alphabet matrix by reciprocal permutation of the rows of the squares, no attempt being made to effect any reciprocal permutation of columns. Figure 61 shows such a matrix. Here, for example, $\overline{AW}_p = \overline{OT}_c$ and $\overline{OT}_p = \overline{AW}_c$; $\overline{BA}_p = \overline{DL}_c$ and $\overline{DL}_p = \overline{BA}_c$, etc.

c. In two-alphabet matrices in which one section is directly above the other, reciprocity already exists without special preparations for its

Figure 62.

production. In figure 62, $MO_p = UA_c$ and $UA_p = MO_c$; $MA_p = MA_c$ and $MA_c = MA_p$. When both θ^1_p and θ^2_p happen to be in the same column, there is no encipherment[6], a fact which constitutes an important disadvantage of this method. This disadvantage is only slightly less obvious in the preceding cases where the cipher equivalent of such a case of $\overline{\theta^1\theta^2}_p$ consists merely of the plain-text letters in reversed order, yielding $\overline{\theta^2\theta^1}_c$.

117. One-Alphabet Matrices; Playfair Cipher

a. Limiting the matrix to one alphabet and modifying the method of finding equivalents gives the basis for a well-known system called the Playfair Cipher, which was not invented by Lord Lyon Playfair but by Sir Charles Wheatstone. It was used for many years as a field cipher in the British Army. For a short time, 1917–18, it was prescribed as a field cipher for use in the United States Army. The modification in the method of finding cipher equivalents has been found useful in imparting a greater degree of security than that afforded in the preceding types of matrix methods. Figure 63 shows a typical Playfair square. The usual method of encipherment can be best explained by examples given under four categories:

(1) Members of the plain-text pair, θ^1_p and θ^2_p, are at opposite ends of the diagonal of an imaginary rectangle defined by the two letters; the members of the cipher-text pair, θ^1_c and θ^2_c, are at the opposite ends of the other diagonal of this imaginary rectangle. Examples: $\overline{MO}_p = \overline{AI}_c$; $\overline{MI}_p = \overline{UC}_c$; $\overline{LU}_p = \overline{QM}_c$; $\overline{VI}_p = \overline{YC}_c$.

[6] Actually, the plain-text digraph is self-enciphered, in that $\overline{\theta^1\theta^2}_p = \overline{\theta^1\theta^2}_c$.

M	A	N	U	F
C	T	R	I	G
B	D	E	H	K
L	O	P	Q	S
V	W	X	Y	Z

Figure 63.

(2) θ^1_p and θ^2_p are in the same row; the letter immediately to the *right* of θ^1_p forms θ^1_c, the letter immediately to the right of θ^2_p forms θ^2_c. When either θ^1_p or θ^2_p is at the extreme right of the row, the first letter in the row becomes its θ_c. Examples: $\overline{MA_p} = \overline{AN_c}$; $\overline{MU_p} = \overline{AF_c}$; $\overline{AF_p} = \overline{NM_c}$; $\overline{FA_p} = \overline{MN_c}$.

(3) θ^1_p and θ^2_p are in the same column; the letter immediately *below* θ^1_p form θ^1_c, the letter immediately below θ^2_p forms θ^2_c. When either θ^1_p or θ^2_p is at the bottom of the column, the top letter in that column becomes its θ_c. Examples: $\overline{MC_p} = \overline{CB_c}$; $\overline{AW_p} = \overline{TA_c}$; $\overline{WA_p} = \overline{AT_c}$; $\overline{QU_p} = \overline{YI_c}$.

(4) θ^1_p and θ^2_p are identical; they are to be separated by inserting a null, usually the letter X or Q. For example, the word BATTLES would be enciphered thus:

BA TX TL ES
DM RW CO KP

b. The Playfair square is automatically reciprocal so far as encipherments of type (1) above are concerned; but this is not true of encipherments of type (2) or (3).

118. Rectangular Designs

a. It is not essential that matrices for digraphic substitution be in the shape of perfect squares; rectangular designs will serve equally well, with little or no modification in procedure. In four-alphabet and two-alphabet rectangles reciprocity can be produced by following the method indicated in paragraph 115.

b. In figures 64 and 65 are shown two examples of such rectangles, together with illustrations of encipherments. Since the English alphabet consists of 26 letters, a number which can only form an impracticable rectangle 2 by 13, and since the addition of any symbols such as the digits 1, 2, 3 . . . to augment the number of elements to 27, 28, 30, 32, 35, or 36 characters would result in producing cryptograms containing intermixtures of letters and figures, the only practicable scheme is to reduce the alphabet to 24 letters as shown in the figures, where I serves also for J and U also for V.

Figure 66.

c. Two-alphabet rectangles are also possible; it is thought unnecessary to demonstrate them by specific examples. The general examples shown in *b* above are considered sufficient.

d. It is possible, however, and it may be practicable to extend the alphabet to 28, 30, or more characters by the subterfuge now to be explained. Suppose one of the letters of the alphabet is omitted from the set of 26 letters, and suppose it is replaced by 2, 3, or more *pairs* of letters, each pair having as one of its members the omitted single letter. Thus, in the case of a one-alphabet Playfair design of rectangular shape, in which the letter K is omitted as a single letter, and the number of characters in the rectangle is made a total of 30 by the addition of five combinations of K with other letters, the rectangle shown in figure 66 may be constructed. An interesting consequence of this modification is that certain irregularities are introduced in the cryptogram, consisting in (1) the occasional replacement of $\overline{\theta^1\theta^2}_p$ by $\overline{\theta^1\theta^2\theta^3}_c$, that is, of a digraph by a trigraph, (2) less frequently, the replacement of $\overline{\theta^1\theta^2\theta^3}_p$ by $\overline{\theta^1\theta^2\theta^3\theta^4}_c$, that is, of a trigraph by a tetragraph, and (3) the appearance of variant values. For example, $\overline{AM}_p = \overline{HKU}_c$; $\overline{GL}_p = \overline{OKO}_c$; $\overline{JK}_p = \overline{KAKE}_c$; $\overline{CK}_p = \overline{BKE}_c$, or $\overline{DKE}_c$, or $\overline{GP}_c$, or $\overline{TP}_c$. So far as the decryptographing is concerned, there would be no difficulty, because the operator always considers any K occurring in the cipher test as invariably forming a ligature with the succeeding letter, taking the pair of letters as a unit. In decryptographing a set of letters, such as $\overline{GP}_c$, he obtains $\overline{CKO}_p$; he disregards the O.

e. As a final note it may be added that it is, of course, possible to insert the letters within a matrix in a less systematic order than that indicated in the various examples. *The letters may be inserted at random or by following the principles of systematically-mixed alphabets, so that no definite sequence is apparent in the matrix.*

119. Combined Alphabetical and Numerical Matrix

a. Figure 67 shows a 4-section matrix which presents a rather interesting feature in that it makes possible the substitution of 3-figure com-

REF ID:A56932

binations for digraphs in a unique manner. To encipher a message one proceeds as usual to find the numerical equivalents of a pair, and then these numbers are added together. Thus:

Plain text:	PR	OC	EE	DI	NG
	275	350	100	075	325
	9	13	24	18	7
Cipher text:	284	363	124	093	332

	A	B	C	D	E	000	025	050	075	100	
	F	G	H	I	K	125	150	175	200	225	
Sec. 1 (θ^1_p)	L	M	N	O	P	250	275	300	325	350	Sec. 3 (θ^1_c)
	Q	R	S	T	U	375	400	425	450	475	
	V	W	X	Y	Z	500	525	550	575	600	
	0	1	2	3	4	V	Q	L	F	A	
	5	6	7	8	9	W	R	M	G	B	
Sec. 4 (θ^2_c)	10	11	12	13	14	X	S	N	H	C	Sec. 2 (θ^2_p)
	15	16	17	18	19	Y	T	O	I	D	
	20	21	22	23	24	Z	U	P	K	E	

Figure 67.

b. To decipher such a cryptogram, take the greatest multiple of 25 contained in the group of three digits; this multiple and its remainder form the elements for determining the plain-text pair in the usual manner. Thus, 284 = 275 + 9 = PR.

Section III. COMPLEX SUBSTITUTION SYSTEMS

120. General

In paragraph 64, brief reference was made to more complex substitution systems. It was stated that there are certain polyalphabetic methods in which periodicity is absent; there are other methods in which the external manifestation of periodicity in cryptograms is prevented, or in which it is suppressed or disguised. Slight hints were then given as to the nature of some of these methods. This and the next two sections give a more detailed description and discussion of the methods indicated, which, as a class, may be designated as *aperiodic* systems, as contrasted with the previously described, more simple *periodic* systems.

REF ID:A56932

121. Continuous or Nonrepeating-Key Systems

a. One of the simplest methods of avoiding periodicity occasioned by the employment of more than one substitution alphabet is to use as the key for the encipherment of one or more messages a series of letters or characters that does not repeat itself. The running text of a book, identical copies of which are in possession of the correspondents, may serve as the key for this purpose. It is only necessary for the correspondents to agree as to the starting point of the key, or to arrange a system of indicating this starting point in the text of the cryptogram. Such a system is called a continuous-key system. Other names applied to it are *nonrepeating, running,* or *indefinite-key* systems. Telephone directories, the Bible, standard reference works, etc., are often used as source books for such keys.

b. Various types of cipher alphabets may be employed in this system, direct or reversed standard alphabets, mixed alphabets drawn up at random, or secondary mixed alphabets resulting from the interaction of two primary sliding mixed components.

c. As an example of the method of cryptographing, suppose the following message is to be enciphered on the continuous key principle, using as the key the text of this subparagraph, beginning AS AN EXAMPLE . . . , and reversed standard alphabets:

HEAVY INTERDICTION FIRE FALLING AT . . . .

Key text:	ASANE XAMPL EOFTH EMETH ODOFC RYPTO . . .
Plain text:	HEAVY INTER DICTI ONFIR EFALL INGAT . . .
Cryptogram:	TOASG PNTLU BGDAZ QZZLQ KYOUR JLJTV . . .

122. Auto-Key Systems

a. The cipher letters of a cryptogram may serve as keyletters, thus automatically furnishing a key. Suppose, for example, that two correspondents agree to use the word TRUE as an initial key, and suppose the message to be enciphered (with the obsolete U. S. Army cipher disk) is as follows:

HEAVY INTERDICTION FIRE FALLING AT . . . .

The first four letters are enciphered as shown:

Key text:	TRUE
Plain text:	HEAVY INTER DICTI ONFIR EFALL INGAT . . .
Cryptogram:	MNUJ

The cipher letters MNUJ now form the keyletters for enciphering the next four plain-text letters, YINT, yielding OFHQ. The latter then form the keyletters for enciphering the next four letters, and so on, yielding the following:

REF ID:A56932

SECRET

Key text: TRUEM NUJOF HQKOE IIVWU VQODR LOSGD . . .
Plain text: HEAVY INTER DICTI ONFIR EFALL INGAT . . .
Cryptogram: MNUJO FHQKO EIIVW UVQOD RLOSG DBMGK . . .

b. Instead of using the cipher letters in sets, as shown, the last cipher letter given by the use of the keyword may become the keyletter for enciphering the plain-text letter; the cipher resultant of the latter then becomes the keyletter for enciphering the following letter, and so on to the end of the message. Thus:

Key text: TRUEJ LDQXT CZRPW OANIA JFAAP EWJDA . . .
Plain text: HEAVY INTER DICTI ONFIR EFALL INGAT . . .
Cryptogram: MNUJL DQXTC ZRPWO ANIAJ FAAPE WJDAH . . .

c. It is obvious that an initial keyword is not necessary; a single prearranged letter will do.

d. The plain text itself may serve as a key, after an initial group or an initial letter. This is shown in the following example, wherein the text of the message itself, after the prearranged initial keyword TRUE, forms the key text:

Key text: TRUEH EAVYI NTERD ICTIO NFIRE FALLI . . .
Plain text: HEAVY INTER DICTI ONFIR EFALL INGAT . . .
Cryptogram: MNUJJ WNCUR KLCYV UPOAX JAIGT XNFLP . . .

e. Although reversed standard alphabets have been used in all the foregoing examples, it is obvious that various types of alphabets may be employed, as prearranged.

f. The following method, although it may at first appear to be quite different, is in reality identical with those just described. A mixed sequence is prepared and its elements numbered in sequence. Let the mixed sequence be derived from the keyword PERMUTABLY:

6	3	7	5	9	8	1	2	4	10
P	E	R	M	U	T	A	B	L	Y
C	D	F	G	H	I	J	K	N	O
Q	S	V	W	X	Z				

A J B K E D S L N M G W P C Q R F V T I Z U H X Y O
1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16 17 18 19 20 21 22 23 24 25 26

Let the message be the same as before, and let the first letter be its own cipher equivalent. Each cipher letter from that point on is produced in turn by finding the sum of the numerical equivalents of the preceding cipher letter and the plain-text letter to be enciphered. When this total exceeds 26, the latter amount is deducted and the letter equivalent of the remainder is taken for the cipher letter. Thus:

REF ID:A56932

Key text:	0	23	2	3	21	20	14	23	16	21	11	17	11	25	18	12	12
Plain text:	H	E	A	V	Y	I	N	T	E	R	D	I	C	T	I	O	N
Numerical value:	23	5	1	18	25	20	9	19	5	16	6	20	14	19	20	26	9
Keyed value:		28	3	21	46	40	23	42	21	37	17	37	25	44	38	38	21
(less 26 or 52 if necessary):	23	2	3	21	20	14	23	16	21	11	17	11	25	18	12	12	21
Cipher text:	H	J	B	Z	I	C	H	R	Z	G	F	G	Y	V	W	W	Z
Key text:	21	12	6	22	1	18	19	1	9	3	12	23	24				
Plain text:	F	I	R	E	F	A	L	L	I	N	G	A	T				
Numerical value:	17	20	16	5	17	1	8	8	20	9	11	1	19				
Keyed value:	38	32	22	27	18	19	27	9	29	12	23	24	43				
(less 26 or 52 if necessary):	12	6	22	1	18	19	1	9	3	12	23	24	17				
Cipher text:	W	D	U	A	V	T	A	N	B	W	H	X	F				

g. In the foregoing example the successive cipher letters form the successive keyletters; but, as noted in *d* above, the successive plain-text letters may serve as the successive keyletters.

h. The same results can be obtained by the use of sliding strips bearing the mixed alphabet. Study the following diagram showing the successive positions of the movable strip and compare the results with those obtained in *f* above.

REF ID:A56932

i. One serious objection to such autokey systems is that the results of errors are cumulative; one error affects all the succeeding letters, and if several errors are made, the messages are difficult to decryptograph. It is possible that this disadvantage can be minimized by the use of automatic cipher devices suitably constructed to accomplish the encipherment with speed and accuracy.

123. Progressive-Alphabet Systems

a. The special characteristic of these systems is that the members of a whole set of cipher alphabets are employed one after the other in progression and in a definite sequence. These systems are periodic in nature and the length of the period is usually equal to the total number of different cipher alphabets employed in the system. The sequence in which the various cipher alphabets are used may or may not change with each message; if it does, this constitutes an additional element of secrecy.

b. To illustrate what is meant by a progressive system a simple example will be given, employing the obsolete U. S. Army Cipher Disk. Starting with the disk so that $A_p = A_c$ (or with any other prearranged initial setting), the first letter of the message is enciphered; the revolving alphabet is then moved one step clockwise (or counter-clockwise) and the second letter is enciphered, and so on. After 26 letters have been enciphered, the disk has returned to its initial starting point and a second cycle begins (if the message is longer than 26 letters). Thus, the period in this case is 26 letters. It is obvious that the displacement of the revolving disk may occur after every 2, 3, 4 . . . . letters, as prearranged, in which case the period increases correspondingly in length. The displacement may, however, be more complicated than this, and may occur after a constantly varying number of letters has been enciphered, whereupon periodicity is suppressed.

c. Two sliding mixed components may be employed, producing a set of 26 secondary mixed alphabets.

d. Another variation is more complicated. Suppose the correspondents draw up a set of 100 random-mixed cipher alphabets, each accompanied by a designating number from 00 to 99, and a set of numerical keys composed of randomized sequences of numbers from 00 to 99. Each such numerical key is designated by an indicator of some sort. To encipher a message, a key sequence is selected and the cryptogram is prepared by means of the sequence of alphabets indicated by the key sequence. If the message is 100 or less letters in length, the alphabets do not repeat; if it is more than 100 letters long, either the sequence of alphabets may repeat or else a new sequence is selected, as prearranged. It is possible to operate the system by means of indicators inserted in the text of the cryptogram.

REF ID:A56932

124. Interrupted or Variable-Key Systems

In certain of the foregoing systems it was noted that periodicity is entirely avoided by the use of a key which is so long that it does not repeat itself; often such a system is referred to as operating in connection with an *indefinite, infinite,* or *unlimited* key as contrasted with one that operates in connection with a *definite, finite,* or *limited* key. But periodicity may also be avoided by special manipulation of a limited key. Several such methods are explained below.

125. Suppressing Periodicity by Encipherment of Variable-Length Groupings of the Plain Text

a. A keyword, though limited in length, may nevertheless be applied to variable or invariable-length sections of the plain text. When, for example, each letter of the key serves to encipher a single letter of the plain text, the encipherment is said to be *invariable* or *fixed* in this respect. The same is true even if a single letter of the key serves to encipher regular sets of letters of the plain text; for example, each letter of the key may serve to encipher 2, 3, 4 . . . . letters of the text. In these cases periodicity would be manifested externally by the cryptograms, providing there is a sufficient amount of text to be examined. But if each letter of the key serves to encipher *irregular* or variable-length groupings of the plain text, then periodicity cannot appear except under rather remote contingencies. Suppose, for example, that so simple a scheme as letting each letter of the key serve to encipher a *complete word* of the text is used; since words are of irregular lengths and there is little or no regularity whatever in the sequence of words with respect only to their lengths, periodicity cannot appear. An example of encipherment will be useful.

b. In the following example the simple cipher disk (direct sequence sliding against reversed sequence) is used, with the key word DEBARK, to encipher the following message, according to the scheme described above. Study it carefully.

```
Key:          D     E      B       A    R    K
Plain text:   COLLECT ALL STRAGGLERS STOP SEND THEM
Cipher:       BPSSZBK ETT JIKBVVQXKJ IHML ZNEO RDGY

Key:          D    E   B
Plain text:   FORWARD AT ONCE
Cipher:       YPMHDMA EL NOZX

Cryptogram:   BPSSZ BKETT JIKBV VQXKJ IHMLZ NEORD
              GYYPM HDMAE LNOZX
```

c. Instead of enciphering according to natural word lengths, the irregular groupings of the text may be regulated by other agreements. For

REF ID:A56932

example, suppose that it is agreed that every keyletter will encipher a number of letters corresponding to the numerical value of the keyletter in the normal alphabet. The foregoing example then becomes as follows:

```
Key:          D     E   B  A          R
Plain text:   COLL ECTAL LS T RAGGLERSSTOPSENDTH
Cipher:       BPSS ACLET QJ H ARLLGNAZZYDCZNEOYK

Key:             K       D
Plain text:   EMFORWARDAT ONCE
Cipher:       GYFWTOKTHKR PQBZ

Cryptogram:   BPSSA CLETQ JHARL LGNAZ ZYDCZ NEOYK
              GYFWT OKTHK RPQBZ
```

d. The foregoing example employed reversed standard alphabets, but mixed alphabets of all types may readily be used.

e. If the keyword is short, and the message long, periodicity may creep in despite the irregular groupings in the encipherment. Sufficient evidence may even be obtained to lead to a disclosure of the length of the key. But if the key consists of a long word, or of a complete phrase or sentence, the text would have to be very long in order that sufficient evidences of periodicity be found to make possible the determinaton of the length of the key.

126. Suppressing Periodicity by Encipherment by Variable-Length Groupings of the Key

a. In paragraph 125*b* periodicity was suppressed by enciphering variable-length groupings of the text; in this paragraph it will be shown how periodicity may be suppressed by enciphering by variable-length groupings of the key. The method consists in *interrupting* the key.

b. Given a keyword, it can become a variable-length key by interrupting it according to some prearranged plan, so that it becomes equivalent to a series of keys of different lengths. Thus, the single keyword UNPREPAREDNESS may be expanded to a sequence of irregular lengths, such as UNPREP/UNP/UNPREPAR/UNPR/UNPREPARE/UNPREPAREDN/U/UNPRE, etc. Various schemes for indicating or determining the interruptions may be adopted. For example, suppose it may be agreed that the interruption will take place immediately after and every time that the letter R occurs in the plain text. The key would then be interrupted as shown in the following example:

```
Key:          UNPUN UNPRE PARED UNPRE UNPRU NP . . .
Plain text:   OURFR ONTLI NESAR ENOWR EPORT ED . . .
```

c. It is possible to apply an interrupted key to variable-length groupings of the plain text. In illustrating this method, an indicator, the letter

REF ID:A56932

X, will be inserted in the plain text to show when the interruption takes place. The plain text is enciphered by natural word lengths.

```
Key:         U     N     U     N     P     U
Plain text:  OUR FRONTX LINES ARE NOWX REPORTED
```

d. It is also possible to interrupt the key regularly, cutting it up into equal length sections as, for example, with the keyword EXTINGUISHER: EXT/XTI/TIN/ING/NGU/GUI/UIS/ISH/SHE/HER. Each set of three keyletters may serve to encipher a set of three plain-text letters. But it is possible to make each set of three keyletters apply to more than three plain-text letters, or to irregular groupings of plain-text letters. For example, suppose a numerical key be derived from the keyword:

```
E  X  T  I  N  G U  I  S  H  E  R
1-12-10—5—7—3-11—6—9—4—2—8
```

Let this numerical sequence determine how many letters will be enciphered by each grouping of the key. The example below will illustrate (reversed standard alphabets are used):

```
Numbers:      1        12          10          5
Key:          E XTIXTIXTIXTI TINTINTINT INGIN
Plain text:   C OLLECTALLSTR AGGLERSSTO PSEND
Cipher:       C JIXTRPXIXFAR TCHIEWBQUF TVCVK

Numbers:         7      3      11
Key:          NGUNGUN GUI UISUISU
Plain text:   THEMFOR WAR DATONCE
Cipher:       UZQBBGW KUR RIZGVQQ

Cryptogram:   CJIXT RPXIX FARTC HIEWB QUFTV
              CVKUZ QBBGW KURRI ZGVQQ
```

e. Another simple method of prearranging the interruption of a keyword or of plain text is to employ the sequence of numbers given by reducing an incommensurate fraction to decimals. For example, the fraction 1/7 yields the sequence 142857142857 . . . This fraction may be represented by the indicator letter H given as the initial letter of the cryptogram.

127. Cipher Devices in Which Periodicity Is Avoided

There are certain cipher devices which operate in such a manner that periodicity is avoided or suppressed. Some of them are discussed in section I, chapter 11. Among them one of the most interesting is that invented by Sir Charles Wheatstone in 1867. As a rule, however, cipher devices, by their very nature, can hardly avoid being cyclic in operation, thus causing periodicity to be exhibited in the cryptograms.

REF ID:A56932

CHAPTER 10
REPETITIVE AND COMBINED SYSTEMS

Section I. REPETITIVE SYSTEMS

128. Superencipherment

a. When, for purposes of augmenting the degree of cryptographic security, the plain text of a message undergoes a first or primary encipherment and the resulting cipher text then undergoes a second or secondary encipherment, the system as a whole is often referred to as one involving superencipherment. If the two or more processes are well selected, the objective is actually reached, and the resulting cryptograms present a relatively great degree of cryptographic security; but sometimes this is not accomplished and the augmented security is of a purely illusory character. The final cryptographic security may, in fact, be no greater in degree than if a single encipherment had been effected, and in unusual cases it may even be less than before.

b. It is impossible to describe all the combinations that might be employed; only a very few typical cases can here be treated, and these will be selected with a view to illustrating general principles. It is possible to pass a message through 2, 3, . . . successive processes of substitution; or through 2, 3, . . . successive processes of transposition; or substitution may be followed by transposition or vice versa. An example of each type will be given.

c. It will be convenient to adopt the symbol C to represent the cipher text produced by any unspecified process of encipherment. The symbols C_1, C_2, C_3, . . . , will then represent the successive texts produced by successive processes in superencipherment. The subscript letter *s* or *t* may be prefixed to the C to indicate that a given process is one of substitution or of transposition. Thus, the steps in a system where a first substitution is followed by a second substitution can be represented symbolically by $sC_1 \rightarrow sC_2$. In a similar manner, $tC_1 \rightarrow tC_2$ represents double transposition. The symbol $sC_1 \rightarrow tC_2$ means that the text from a first process of substitution undergoes transposition as a second process.

129. Repetitive Transposition Systems

These have been dealt with in Chapter 8, Sections II and III, and need no further discussion at this point. It was there shown that properly

REF ID:A56932

selected transposition methods, when repetitive in character, can produce cryptograms of very great security.

130. Repetitive Monoalphabetic Substitution Systems

Suppose a message undergoes a primary encipherment by means of a single-mixed, nonreciprocal alphabet, and the primary cipher text undergoes a secondary encipherment by means of the same or a *different* mixed alphabet. The resulting cryptogram is still monoalphabetic in character, and presents very little, if any, augmentation in the degree of security (depending upon the type of alphabet employed). Here an entirely illusory increase in security is involved and an ineffectual complexity is introduced; the process may indeed be repeated indefinitely without producing the desired result. This is because the fundamental nature of monoalphabetic substitution has not been taken into consideration in the attempts at superencipherment; $sC_1 \rightarrow sC_2 \rightarrow sC_3 \ldots$, still remains monoalphabetic in character.

131. Repetitive Polyalphabetic Substitution Systems

a. If the primary encipherment is by means of the repeating-key principle, with standard alphabets, and the secondary encipherment is similar in character, with similar alphabets, and a key of similar length, the final cryptogram presents no increase in security at all. Thus, if the key BCDE is used in the primary encipherment (Vigenère Method) and the key FGHI is used in the secondary encipherment, the final result is the same as though the key GIKM had been used in a single encipherment.

b. If mixed alphabets are used, and if those of the primary and the secondary encipherment belong to the same series of secondary alphabets resulting from the sliding of two primary sequences against each other, the results are similar in character to those described in *a* above. They are identical with those that would be obtained by an equivalent single encipherment by the appropriate secondary alphabets.

c. If the key for the secondary encipherment is of a different length from that for the primary encipherment, the results are, however, somewhat different, in that the period of the resultant cryptogram becomes the least common multiple of the two key lengths. For example, if the length of the key for the primary encipherment is 4, that for the secondary 6, the result is the same as though a key of 12 elements had been employed in a single encipherment. This can be demonstrated as follows, using the keys 4–1–2–3 and 5–2–6–1–4–3:

4 1 2 3 4 1 2 3 4 1 2 3	4 1 2 3 4 1 2 3 4 1 2 3	4 1 2 3 . . .
5 2 6 1 4 3 5 2 6 1 4 3	5 2 6 1 4 3 5 2 6 1 4 3	5 2 6 1 . . .
9 3 8 4 8 4 7 5 10 2 6 6	9 3 8 4 8 4 7 5 10 2 6 6	9 3 8 4 . . .

REF ID:A56932

d. The degree of cryptographic security is, without doubt, increased by such a method. If the key lengths are properly selected, that is, if they present no common multiple less than their product, the method may give cryptograms of great security. For example, two keys that are 17 and 16 characters in length would give a cryptogram that is equivalent in period to that of a cryptogram enciphered once by a key 17×16, or 272 elements in length. The fundamental principle of an excellent, though complicated, printing telegraph cipher system is this very principle.

Section II. COMBINED SYSTEMS

132. Combined Monoalphabetic and Polyalphabetic Substitution Systems

a. If a message undergoes a primary encipherment by the repeating-key method, using standard alphabets, and the primary cipher text then undergoes a secondary encipherment by means of a single-mixed alphabet, the degree of cryptographic security is increased to the same extent that it would be if the original message had undergone the same primary encipherment with secondary alphabets resulting from the sliding of a mixed primary sequence against the normal sequence. This increase in security is not very great.

b. The same is true if the primary encipherment is monoalphabetic and the secondary encipherment is polyalphabetic by the method described.

c. In general, this also applies to other types of polyalphabetic and monoalphabetic combinations. The increase in security is not very great, and is, indeed, much less than the uninitiated suspect.

133. Combined Substitution-Transposition in General

Combinations of substitution and transposition methods can take many different forms, and only a few examples can be illustrated herein. It is possible of course, to apply substitution first, then transposition, or transposition first, then substitution. The most commonly encountered systems, however, are of the former type, that is $s\mathrm{C}_1 \rightarrow t\mathrm{C}_2$. Furthermore, it can be stated that as a rule practicable systems in which both processes are combined use methods that are relatively simple in themselves, but are so selected as to produce cryptograms of great security as a result of the combination. To give a very rough analogy, in certain combinations the effect is much more than equivalent to the simple addition of complexities of the order X and Y, giving $X+Y$; it is more of the order XY, or even X^2Y^2.

REF ID:A56932

134. Monoalphabetic and Polyalphabetic Substitution Combined with Transposition

a. A message may undergo simple monoalphabetic substitution or complex polyalphabetic substitution and the resulting text passed through a simple transposition. Obviously, either standard or mixed alphabets may be employed for the substitution phase and for the transposition phase any one of the simple varieties of geometric-design methods may be applied.

b. As an example, note the following simple combination, using the message ALL ACTION AT LANDING BEACH HAS CEASED. 1st step: sC_1 (monoalphabetic, by mixed alphabet):

Plain: ABCDEFGHIJKLMNOPQRSTUVWXYZ
Cipher: TDRAMOBNILPEZYXWVUSQKJHGFC

Message: ALLAC TIONA TLAND INGBE ACHHA SCEAS ED
Cipher: TEETR QIXYT QETYA IYBDM TRNNT SRMTS MA

2d step: tC_2 (as prearranged between correspondents):

TEETRQIX (For the inscription; a rectangle of eight columns.)
YTQETYAI
YBDMTRNN (For the transcription; counterclockwise route beginning
TSRMTSMA at lower right hand corner.)

Cryptogram: ANIXI QRTEE TYYTS RMTSM NAYTE QTBDM TR

c. A simple subterfuge often adopted between correspondents is to write the substitution text backwards to form the final cryptogram (a case of simple reversed writing).

d. An extremely simple and yet effective transposition method (when its presence is not suspected) sometimes employed as a preliminary to substitution is that in which the text of a message is first divided into halves; the second being placed under the first as in rail-fence writing. Thus:

P O E D O O T F M A K T O
R C E T P R O E B R A I N

Then encipherment by simple monoalphabetic methods may be effected and the cipher text taken from the two separate lines. Thus, if a standard alphabet one letter in advance were used, the text would be as follows:

Q P F E P P U G N B L U P
S D F U Q S P F C S B J O

Cryptogram: QPFEP PUGNB LUPSD FUQSP FCSBJ O

REF ID:A56932

e. A simple variation of the foregoing method which is frequently effective with true digraphic methods of substitution is to write θ^2_p under θ^1_p and then encipher the sets of juxtaposed $\overline{\theta^1\theta^1}_p$ letters digraphically, then the sets of juxtaposed $\overline{\theta^2\theta^2}_p$ letters. Thus, let the message be WILL RETURN AT ONCE; it would be written down as follows:[7]

WLRTRAOC
ILEUNTNE

Then the following pairs would be enciphered: $\overline{WL}_p$, $\overline{RT}_p$, $\overline{RA}_p$, $\overline{OC}_p$, $\overline{IL}_p$, etc. The foregoing message enciphered in this manner by means of the Playfair Square shown in figure 63, for example, yields the following cryptogram:

Plain text: WL RT RA OC IL EU NT NE
Cipher: VO IR TN LT CQ HN AR RP
Cryptogram: VOIRT NLTCQ HNARR P

f. Naturally the transposition process may involve groups of letters; a simple type of disarrangement is to reverse the order of the letters in 5-letter groups, or within 5-letter groups a transposition such as 3–2–1–4–5 or 2–1–5–3–4 (any of 120 different arrangements) is possible.

g. Columnar transposition methods lend themselves especially well to combination with substitution methods. An excellent example will be considered under the next section.

135. Polyliteral Substitution Combined with Transposition

In paragraph 111*b* the essential nature of polyliteral substitution as contrasted with monoliteral substitution was discussed. Polyliteral methods make use of polypartite alphabets in which the cipher equivalents are composed of two or more parts. This being the case it is a natural extension of cryptographic processes to *separate* these parts or to distribute them throughout the cipher text so that the components or, so to speak, fractional parts of the cipher equivalents are thoroughly disarranged and distributed evenly or irregularly throughout the text.

136. Fractionating Systems

a. A simple example will first be shown. Let the following bipartite cipher alphabet be drawn up by assigning numerical equivalents from 01 to 26 in mixed sequence to the letters of the normal sequence. Thus:

[7] In preparing the text for encipherment, the clerk must bear in mind that if the normal Playfair system is to be used no doublets can be enciphered. The message WE WILL LEAVE . . would be arranged thus:

WXILXEV
EWLXLAE

REF ID:A56932

A	B	C	D	E	F	G	H	I	J	K	L	M
02	11	06	12	13	05	10	14	09	15	16	17	01

N	O	P	Q	R	S	T	U	V	W	X	Y	Z
03	18	19	20	08	21	07	04	22	23	24	25	26

Each letter is represented by a combination of two digits; in preparing the message for cryptographing, the two digits comprising the cipher equivalent of a letter are written one below the other, thus:

Plain text: ONE PLANE REPORTED LOST

Cipher θ^1_c: 101 11001 01110011 1120

Cipher θ^2_c: 833 97233 83988732 7817

By recombining the single digits in pairs, reading from horizontal lines, and writing down the pairs in unchanged numerical form, one obtains the following:

10 11 10 01 01 11 00 11 11 20
83 39 72 33 83 98 87 32 78 17

b. The foregoing cipher text can be transmitted in 5-figure groups, or it can be reconverted into letters by one means or another, but some difficulties are encountered in the latter case because every one of 100 different pairs of digits has to be provided for, thus necessitating a 2-letter substitution, which would make the cipher text twice as long as the plain text.

c. In the methods to follow presently, these difficulties are avoided by a simple modification. This modification consists in the employment of true *polyfid cipher alphabets,* that is, polypartite alphabets in which the plain component is the normal sequence and the cipher component consists of a sequence of equivalents composed of all the permutations of 2, 3, 4, . . . symbols taken in definite groups. For example, a *bifid alphabet*[8] composed of permutations of five digits taken two at a time can be constructed, yielding a set of 25 equivalents for a 25-letter alphabet (I and J being usually considered as one letter). A *trifid alphabet* of 27 equivalents can be constructed from *all* the permutations of the digits 1, 2, 3, taken three at a time; an extra character must, however, be added to represent the 27th element of the alphabet. It is convenient to represent the parts of a bifid equivalent by the symbols θ^1_c and θ^2_c, the parts of a trifid equivalent, by the symbols θ^1_c, θ^2_c and θ^3_c.

[8] Such an alphabet should be clearly differentiated from a *biliteral alphabet.* In the latter, two and only two elements are employed, in groups of fives, yielding 25 or 32 permutations. The Biliteral Cipher of Sir Francis Bacon and the Baudot Alphabet of modern printing telegraph systems are based upon alphabets that are typical examples of biliteral alphabets. The designation *digraphic alphabet* will be applied to one in which the cipher equivalents are composed of any number of symbols, *n,* taken simply in groups of two, these symbols not being permuted in systematic fashion to produce a complete set of 2^n equivalents.

REF ID:A56932

d. Polyfid cipher alphabets may be systematically-mixed alphabets based upon keywords and keyphrases. For example, note how the following bifid alphabet is derived from the keyphrase XYLOPHONIC BEDLAM:

X	Y	L	O	P	H	N	I	C	B	E	D	A
11	12	13	14	15	21	22	23	24	25	31	32	33

M	F	G	K	Q	R	S	T	U	V	W	Z
34	35	41	42	43	44	45	51	52	53	54	55

The same principle may be applied to trifid alphabets, employing the permutations of the three digits 1, 2, and 3, taken in groups of three.

e. Note the following bifid alphabet and the example of its use in enciphering a message:

A	B	C	D	E	F	G	H	I-J	K	L	M
12	31	21	32	33	15	25	34	24	35	41	11

N	O	P	Q	R	S	T	U	V	W	X	Y	Z
13	42	43	44	23	45	22	14	51	52	53	54	55

Message: ONE PLANE REPORTED LOST

Cipher θ^1_c: 413 44113 23442233 4442

Cipher θ^2_c: 233 31233 33323232 1252

The bifid elements, θ^1_c and θ^2_c, are now recombined horizontally in pairs and the pairs are reconverted into letter equivalents of the basic alphabet which, for the sake of convenience, is here arranged in the form of a deciphering alphabet:

11	12	13	14	15	21	22	23	24	25	31	32	33
M	A	N	U	F	C	T	R	I	G	B	D	E

34	35	41	42	43	44	45	51	52	53	54	55
H	K	L	O	P	Q	S	V	W	X	Y	Z

Cryptogram: LHLNR QTEQO REAEE DDDAW

f. It will be noted that there are four basic steps involved in the foregoing encipherment: (1) A process of decomposition, substitutive in character, in which each θ_p is replaced by a bipartite θ_c, composed of two parts, θ^1_c and θ^2_c, according to a bifid alphabet; (2) a process of separation, transpositive in character, in which each θ^1_c is separated from the θ^2_c with which it was originally associated; (3) a process of recombination, also transpositive in character, in which each θ^1_c is combined with a θ^2_c with which it was not originally associated; and finally (4) a process of recomposition, substitutive in character, in which each new θ^1_c θ^2_c combination is given a letter value according to a bifid alphabet. In the foregoing example (*e* above), the alphabet for the recomposition was the same as that for the decomposition; this,

REF ID:A56932

of course, is not an inherent necessity of the system; the decomposition and recomposition alphabets may be entirely different. This is shown in the example in paragraph 137*d*.

137. Comparison of Foregoing Fractionating System with Certain Digraphic Systems

a. The method described in paragraph 136*e* can be identified with some of the digraphic substitution systems discussed in chapter 9, section I.

b. Take the message of paragraph 136*e* and let a slight modification in the method of recombining θ^1_c and θ^2_c be made. Specifically, let the first halves and the second halves of the bifid equivalents of the plain-text letters be combined in the following manner, using the bifid alphabet of paragraph 136*e*:

Message: ONE PLANE REPORTED LOST

ON	EP	LA	NE	RE	PO	RT	ED
41=L	34=H	41=L	13=N	23=R	44=Q	22=T	33=E
23=R	33=E	12=A	33=E	33=E	32=D	32=D	32=D

LO	ST
44=Q	42=O
12=A	52=W

Cryptogram: LRHEL ANERE QDTDE DQAOW

If the cryptogram given in paragraph 136*e* were split in the middle into two sections, and the letters taken alternately, the result would be identical with that obtained in this subparagraph. The identification referred to in *a* above is demonstrated in *c* below.

c. Note the two alphabet matrix shown in figure 68. If the same message is now enciphered by its means, a cryptogram identical with that obtained in *b* above will be obtained. Thus:

M	A	N	U	F
C	T	R	I	G
B	D	E	H	K
L	O	P	Q	S
V	W	X	Y	Z

M	C	B	L	V
A	T	D	O	W
N	R	E	P	X
U	I	H	Q	Y
F	G	K	S	Z

Message:

ONE PLANE REPORTED LOST

Substitution of pairs:

$ON_p = LR_c$; $EP_p = HE_c$; $LA_p = LA_c$; $NE_p = NE_c$; $RE_p = RE_c$; etc.

Cryptogram:

LRHEL ANERE etc.

Figure 68.

REF ID:A56932

d. In the example in paragraph 136*e*, the same bifid alphabet was used for the recomposition as for the decomposition. Instead of converting the combined θ^1_e θ^2_e elements into letters by means of the original bifid alphabet, suppose a second bifid alphabet specifically drawn up for this recomposition is at hand (see par. 136*f*). Thus:

11=A	21=B	31=C	41=K	51=V
12=U	22=I	32=D	42=N	52=W
13=T	23=L	33=F	43=P	53=X
14=0	24=E	34=G	44=Q	54=Y
15=M	25=S	35=H	45=R	55=Z

The encipherment of the message is then as follows:

Message: ONE PLANE REPORTED LOST.

Alphabet for decomposition		*Alphabet for recomposition*	
A=12	N=13	11=A	34=G
B=31	0=42	12=U	35=H
C=21	P=43	13=T	41=K
D=32	Q=44	14=0	42=N
E=33	R=23	15=M	43=P
F=15	S=45	21=B	44=Q
G=25	T=22	22=I-J	45=R
H=34	U=14	23=L	51=V
I-J=24	V=51	24=E	52=W
K=35	W=52	25=S	53=X
L=41	X=53	31=C	54=Y
M=11	Y=54	32=D	55=Z
	Z=55	33=F	

Encipherment:

ON	EP	LA	NE	RE	PO	RT	ED
41=K	34=G	41=K	13=T	23=L	44=Q	22=I	33=F
23=L	33=F	12=U	33=F	33=F	32=D	32=D	32=D

LO	ST
44=Q	42=N
12=U	52=W

Cryptogram: KLGFK UTFLF QDIDF DQUNW

e. Now encipher the same plain-text message by means of the four-alphabet matrix shown in figure 69. The results are as follows:

Message: ONE PLANE REPORTED LOST.

Plain text: ON EP LA NE RE PO RT ED LO ST

Cipher pairs: KL GF KU TF LF QD ID FD QU NW

Cryptogram: KLGFK UTFLF QDIDF DQUNW

The results are identical with those obtained in *d* above.

REF ID:A56932

M A N U F C T R I G B D E H K L O P Q S V W X Y Z	A U T O M B I L E S C D F G H K N P Q R V W X Y Z

Figure 69.

f. If the successive letters of the cryptogram of *b* above are enciphered monoalphabetically by means of the following alphabet, the results again coincide with those obtained in *d* and *e* above.

Alphabet

C_1: A B C D E F G H I-J K L M N O P Q R S T U V W X Y Z
C_2: U C B D F M S G E H K A T N P Q L R I O V W X Y Z

First cryptogram: LRHEL ANERE QDTDE DQAOW
Final cryptogram: KLGFK UTFLF QDIDF DQUNW

138. Fractionating Systems as Forms of Combined Substitution and Transposition

In studying the various types of substitution discussed in chapter 9, section II, it was not apparent, and no hint was given, that these systems combine both substitution and transposition methods into a single method. But the analysis presented in paragraph 137 shows clearly that there is a kind of transposition involved in digraphic methods involving the use of matrices.

139. Fractionation and Recombination within Regular or Variable Groupings of Fractional Elements

a. This method is an extension or modification of that illustrated in paragraph 136*e*. Let the text be written out in groups of 3, 4, 5, . . . letters, as prearranged between the correspondents. Suppose groupings of five letters are agreed upon; a bifid alphabet (that in par. 136*e*) is used for substitution; thus:

Message: ONEPL ANERE PORTE DLOST
41344 11323 44223 34442
23331 23333 32323 21252

REF ID:A56932

Then, let the recombinations be effected *within* the groups horizontally. Thus, for the first group the recombinations are 41, 34, 42, 33, and 31. The entire message is as follows:

41.34.4	11.32.3	44.22.3	34.44.2
2.33.31	2.33.33	3.23.23	2.12.52

Recomposition (using the same bifid alphabet as was used for the decomposition) yields the cryptogram:

LHOEB MDDEE QTERR HQTAW

b. As indicated, other groupings may be employed. Furthermore, a different bifid alphabet for the recomposition may be used than was employed for the original substitution or decomposition. It is also clear that sequences of variable-length groupings may also be employed, as determined by a subsidiary key.

c. Trifid alphabets also lend themselves to these methods. Note the following example:

Alphabet for decomposition			*Alphabet for recomposition*		
A=222	J=312	S=131	111=I	211=U	311=V
B=322	K=112	T=122	112=K	212=N	312=J
C=121	L=231	U=211	113=W	213=H	313=$\overline{\text{ZB}}$
D=133	M=323	V=311	121=C	221=X	321=E
E=321	N=212	W=113	122=T	222=A	322=B
F=123	O=333	X=221	123=F	223=Y	323=M
G=332	P=233	Y=223	131=S	231=L	331=Q
H=213	Q=331	Z=132	132=$\overline{\text{ZA}}$	232=R	332=G
I=111	R=232	?=313	133=D	233=P	333=O

Message: H A S A I R P L A N E R E T U R N E D Y E T ?

H	A	S	A	I	R	P	L	A	N	E	R	E	T	U	R	N	E	D	Y	E	T	?
2	2	1.2	1		2	2	2.2	2		3	2	3.1	2		2	2	3.1	2		3	1	3
1.2	3	2.1			3.3	3	2.1			2.3	2	2.1			3.1	2	3.2			2	2	1
3	2.1	2	1		2	3.1	2	2		1	2.1	2	1		2	2.1	3	3		1	2	3

Cipher text[9]: XUR$\overline{\text{ZA}}$C AYGFT MTBKC YFFAD $\overline{\text{ZB}}$XF
Final cryptogram: XURZA CAYGF TMTBK CYFFA DZBXF

[9] The reason for the regrouping shown in the final cryptogram requires a consideration of the fact that a trifid alphabet involves the use of 27 characters. Since our alphabet contains but 26 letters, either an extra symbol would have to be used (which is impractical) or some subterfuge must be adopted to circumvent the difficulty. This has been done in this case by using $\overline{\text{ZA}}$ and $\overline{\text{ZB}}$ to represent two of the permutations in the recomposition alphabet. In decryptographing, when the clerk encounters the letter Z in the text, it must be followed either by A or by B; according to the alphabet here used, ZA represents permutation 132, and ZB represents permutation 313. In order not to introduce a break in the regulation 5-letter groupings of cipher text, the final cryptogram is regrouped strictly into fives.

REF ID:A56932

d. Bifid and trifid alphabets may be combined within a single system with appropriate groupings, but such combinations may be considered as rather impracticable for military usage.

140. Fractionation Combined with Columnar Transposition

a. An excellent system of combined substitution-transposition that has stood the test of practical, war-time usage is that now to be described. Let a 36-character bipartite alphabet square be drawn up, and a message enciphered, as follows:

	M	O	N	T	H	S
W	H	8	A	1	I	9
I	L	C	3	0	U	M
N	B	2	P	Y	N	D
T	4	E	5	F	6	G
E	7	J	Ø	K	Q	R
R	S	T	V	W	X	Z

(Key for internal alphabet: HAIL COLUMBIA HAPPY LAND. Digits are inserted immediately after each letter from A to J, A being followed by 1, B, 2, etc.)

Message:

ADVANCE PROGRESSING SATISFACTORILY OVER 400 PRISONERS AND 5-75 MM GUNS CAPTURED. SECOND OBJECTIVE REACHED AT 5:15 P. M.

Substitution:

A	D	V	A	N	C	E	P	R	O	G	R	E	S	S
WN	NS	RN	WN	NH	IO	TO	NN	ES	IT	TS	ES	TO	RM	RM
I	N	G	S	A	T	I	S	F	A	C	T	O	R	I
WH	NH	TS	RM	WN	RO	WH	RM	TT	WN	IO	RO	IT	ES	WH
L	Y	O	V	E	R	4	ø	ø	P	R	I	S	O	N
IM	NT	IT	RN	TO	ES	TM	EN	EN	NN	ES	WH	RM	IT	NH
E	R	S	A	N	D	5	7	5	M	M	G	U	N	S
TO	ES	RM	WN	NH	NS	TN	EM	TN	IS	IS	TS	IH	NH	RM
C	A	P	T	U	R	E	D	S	E	C	O	N	D	O
IO	WN	NN	RO	IH	ES	TO	NS	RM	TO	IO	IT	NH	NS	IT
B	J	E	C	T	I	V	E	R	E	A	C	H	E	D
NM	EO	TO	IO	RO	WH	RN	TO	ES	TO	WN	IO	WM	TO	NS
A	T	5	1	5	P	M								
WN	RO	TN	WT	TN	NN	IS								

The C_1 text is now inscribed in a rectangle of predetermined dimensions. Transposition rectangle (columnar, based on key HAIL COLUMBIA HAPPY LAND) (see figure 70).

b. One of the important advantages of this type of cipher is that it affords accuracy in transmission since the text is composed of a

REF ID:A56932

OTOTM EMWNN OINT

Figure 70.

limited number of letters. In fact, if the horizontal and vertical coordinates of the cipher square are the same letters, then the cryptographic text is composed of permutations of but six different letters, thus aiding very materially in correct reception. Indeed, it is even possible to reconstruct completely a message that has been so badly garbled that only half of it is present. This cipher system was used with considerable success by the Germany Army in 1917–18, and was known to the Allies as the ADFGVX Cipher, because these were the letters used as horizontal and vertical coordinates of the cipher square, and consequently the cipher text consisted solely of these six letters.

c. The cipher text of the foregoing message is, of course, twice as long as the plain text, but it can be reduced to exactly the original plain-text length by combining the distributed or transposed θ^1_c and θ^2_c elements in pairs, referring to the original (or a different) polypartite square, and recomposing the pairs into letters. In this case, the horizontal and vertical coordinates must be identical in order to permit of finding equivalents for all possible pairs.

REF ID:A56932

CHAPTER 11

CIPHER DEVICES AND CIPHER MACHINES

Section I. CIPHER DEVICES

141. General

The cipher systems previously described by no means exhaust the category of complex systems, but it is impossible to describe them all. Furthermore, each one presents innumerable possibilities for modification in minor respects and for combination with other methods. In the paragraphs to follow, the principles upon which certain of the more simple cipher devices have been based are described.

142. Wheatstone Cipher[10]

a. The device is a little more than four inches in diameter, and consists of a dial with two hands, as shown in figure 71. The dial is composed of two independent circles of letters. In the outer circle the letters progress clockwise in normal alphabetic sequence, but there is an extra character between the Z and the A, making a total of 27 characters. Some of the spaces also have digits inscribed in them, for enciphering numbers. In the inner circle the letters are arranged in mixed alphabetic sequence and are inscribed either on a surface which permits of erasure, or on a detachable cardboard circle which can be removed and replaced by another circle bearing a different sequence. In figure 71 this inner sequence is a systematically mixed sequence derived from the keyword FRANCE, as follows:

1	2	3	4	5	6
F	R	A	N	C	E
B	D	G	H	I	J
K	L	M	O	P	Q
S	T	U	V	W	X
Y	Z				

F B K S Y R D L T Z A G M U N H O V C I P W E J Q X

[10] Credit for the invention of the device and system described in this paragraph belongs not to Sir Charles Wheatstone, as has until recently been thought, but to an American, Decius Wadsworth, who in 1817 constructed a device identical in principle with that described on pp. 342–347 of *The Scientific Papers of Sir Charles Wheatstone*, published by the Physical Society of London in 1879. The Wheatstone device used a 27-element outer alphabet (26 letters

REF ID:A56932

b. The two hands are pivoted concentrically, as are the hour and minute hands of a clock. Now, in a clock, the minute hand makes a complete revolution, while the hour hand makes only $\frac{1}{12}$ of a complete revolution; the action in the case of this device, however, is somewhat different. The short hand is free to move independently of the long one, although the motion of the latter affects the former. Since the outer circle has 27 spaces and the inner one only 26, by a simple mechanical contrivance each complete revolution of the long hand causes the short hand to make $1\frac{1}{26}$ revolutions, thus causing the short hand to point one place in advance of where it pointed at the end of the preceding revolution of the long hand. For example, when the long hand is over B of the outer circle and the short hand points to R of the inner circle, if the long hand is pushed clockwise around the dial, making a complete revolution, the short hand will also make a complete revolution clockwise plus one space, thus pointing to D.

c. To encipher a message, the long hand and the short hand are set to prearranged initial positions. It is usual to agree that the plain-text letters will be sought in the outer circle of letters, their cipher equivalents in the inner circle; and that the long hand is invariably to be moved in the same direction, usually clockwise.

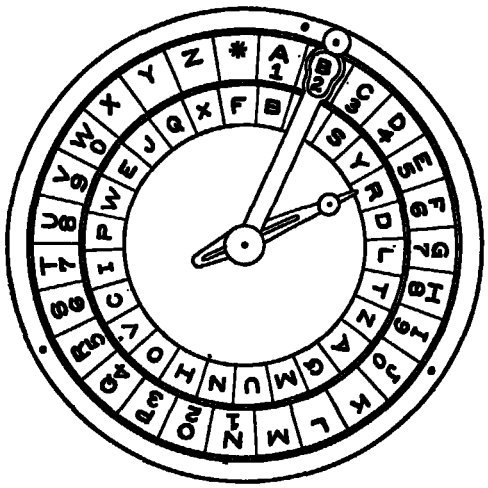

Figure 71.

Suppose the message to be enciphered is SEND AMMUNITION FORWARD. The long hand is moved clockwise until it is directly

and a word-separator), and a 26-element inner alphabet; the Wadsworth device used a 33-element outer alphabet (26 letters and the digits 2–8, inclusive), and a 26-element inner alphabet. Also, whereas in the Wheatstone device only the cipher component could be varied, in the Wadsworth device both components could be varied according to identical or non-identical mixed sequences.

REF ID:A56932

over S on the outer sequence. The letter to which the short hand points is the cipher equivalent of S and is written down. Then the long hand is moved clockwise to a position over E, the letter to which the short hand points is noted and written down. When a double letter occurs in the plain text, as in the case of the double M of AMMUNITION, some infrequently used letter, such as Q, must be substituted for the second occurrence of the letter. To decipher a message, the hands are returned to their initial prearranged position, and then the long hand is moved clockwise until the short hand points to the first cipher letter; the long hand is then directly over the plain-text letter. The process is continued until all the letters have been deciphered.

d. A consideration of the foregoing details shows that the encipherment of a message depends upon a combination of the following variables:

(1) The sequence of letters in the outer circle. In the case just considered, this sequence must be regarded as a known sequence, since it consists merely of the normal alphabet plus one character.
(2) The sequence of letters in the inner circle.
(3) The initial juxtaposition of the two sequences.
(4) The exact composition of the text to be enciphered, since this will determine the number of revolutions of the long hand required to encipher a given number of letters of the message.

e. It is obvious that if the outer alphabet is made a mixed alphabet, as well as the inner, both being different, the cryptograms will be made the more secure against cryptanalysis.

f. The same results as are obtained by using the device can be obtained by using sliding strips of paper, providing the operator will bear in mind that every time a θ_p on the plain component is situated to the left of the preceding θ_p, he must displace the cipher component one interval to the left, if the correspondents have agreed upon a clockwise movement of the long hand, or to the right, if they have agreed upon a counterclockwise movement of the long hand.

143. Jefferson Cipher

a. Credit for the invention of the cipher system and device now to be described belongs to Thomas Jefferson,[11] the original inventor,

[11] The late John M. Manly, Ph. D., formerly Captain, Military Intelligence Division, U. S. A., discovered, in 1922, a description of the device among Jefferson's Papers in the Library of Congress (vol. 232, item 41575, Jefferson's Papers). For a photographic reproduction of this historically interesting item, see pp. 189–91 of *Articles on Cryptography and Cryptanalysis Reprinted From The Signal Corps Bulletin*, Signal Security Service Publication, OCSigO, Washington, 1942.

REF ID:A56932

although it was independently invented many years later (1891) by a French cryptographer, Commandant Bazeries, and still later (1914) by Captain Parker Hitt, U. S. Army (now Colonel, U. S. Army, Ret.). Because it was first described in print (1901) by Bazeries, the principle upon which the cipher system is based is usually referred to in the literature as the Bazeries principle; for the sake of historical accuracy, however, it is herein called the Jeffersonian principle.

b. The basis of this principle is the use of a set of 20 (or more, if desired) mixed alphabets arranged in a sequence that can readily be changed; these can be used in the encipherment of a whole set of 20 letters with one and the same displacement of the alphabets. Successive encipherments are accomplished with different displacements of the alphabets.

c. Whereas Jefferson contemplated a device using a total of 36 different alphabets mounted on revolvable disks, the one Bazeries described used only 20 alphabets mounted in the same manner.

144. The Obsolete U. S. Army Cipher Device, Type M–94

a. This cipher device is based upon the Jeffersonian principle, using 25 mixed alphabets on small aluminum disks. It was widely employed in the U. S. military service and to a more limited extent in other U. S. services until 1942, when it was superseded by better devices.

b. In using the device, the 25 disks were first arranged according to the key for the day (the disks bearing the identifying numbers 1–25, and also the letters B–Z), and then the first twenty-five letters of the plain text were set up along a guide rule. The cipher text consisted of *any* one of the other rows, which would be taken off in five groups of five letters each. This process continued until the entire message was enciphered. To decryptograph, it was merely necessary for the deciphering clerk to set up along the guide rule of the device (properly arranged according to the daily key) the first twenty-five letters of the cipher text, and then by inspection find the one and only one row of letters that constituted plain text, which process would be repeated until the entire message was deciphered.

145. Strip Cipher Systems

a. A modification of the Jeffersonian principle which has found merit in practical cryptography is the strip cipher system. This is nothing more than a series of printed, random-alphabet strips to take the place of the disks of the cylindrical devices. These strips, bearing identifying numbers, slide freely in a strip board which may be made of metal, wood, or plastic. The strips are simpler to produce and more economical to replace than metal disks.

REF ID:A56932

b. It is possible to incorporate modifications of the basic idea of the Jeffersonian principle in using strip systems. For instance, there may be a daily selection of strips from a set consisting of a much larger number; or there may be different sets of strips for messages in the various security classifications; or different sets of strips may be issued to different groups of holders, etc.

Section II. CIPHER MACHINES

146. Importance of Cipher Machines in Modern Cryptographic Communication

The remarks made in paragraph 2 regarding the present trends in the art, are believed to be sufficient to give a clear idea of the importance of a knowledge of the uses and limitations of cipher machines as adjuncts to modern cryptographic communications. However, in this text only observations of a general character can be made, leaving for a future text an exposition of detailed principles involved in the construction and operation of a few typical cipher machines. More and more attention is today being devoted to this phase of cryptography and to a large extent cipher machines have replaced code systems even in lower headquarters, except for small, special-purpose codes.

147. Transposition-Cipher Machines

These are rarely encountered; the files of United States patents disclose but two examples and so far as is known no actual machines have been constructed conforming to the specifications covered therein. It may be said that substitution methods lend themselves so much more readily to automatic encipherment than do transposition methods that the possibilities for the construction of cipher machines for effecting transpositions are almost completely overlooked. Basically it would seem that a machine for effecting transposition would have to include some means for "storing up" the letters until all the plain text has been "fed into the machine," whereupon the transposing process is begun and the letters are finally brought out in what externally appears to be a randomized order. It is conceivable that a machine might be devised in which the disarrangement of the letters is a function merely of the number of letters comprising the message; daily changes in the randomizing machinery could be provided for by resetting the elements controlling the process.

148. Substitution-Cipher Machines

a. The substitution principle lends itself very readily to the construction of cipher machines for effecting it. The cipher devices described in the

REF ID:A56932

preceding section, as well as the simpler varieties making use merely of two or more superimposed, concentric disks are in the nature of hand-operated substitution-cipher mechanisms that are difficult to use, cannot be employed for rapid or automatic cryptographic manipulations, and are quite markedly susceptible to errors in their operation. For a long time these defects have been recognized and many men have striven to produce and to perfect devices more automatic in their functioning. However, the would-be inventors have not, as a rule, realized the complexity of the problems confronting them; nor have they approached these problems with the necessary and thorough knowledge of both theoretical and practical cryptography, with its many limitations, and theoretical as well as practical cryptanalysis, with its wide possibilities for the exercise of human ingenuity. However, when the problem of developing and producing a good cipher machine is attacked by a competent cryptographic and cryptanalytic engineering staff, highly efficient cipher machines can be developed. At this writing some very excellent machines are now in actual use for practical secret communications.

b. It is obvious that automatic devices of this nature should be equipped with a keyboard of some kind, resembling or duplicating that of an ordinary typewriter. Furthermore, for rapid manipulation these machines must be actuated by mechanisms affording speed in operation, such as electric or spring motors, compressed air, electromagnets, etc.

149. Machines Affording Only Monoalphabetic Substitution

Little need be said of those machines in which the ordinary keys of the keyboard are merely covered with removable caps bearing other letters or characters. They yield only the simplest type of substitution cipher known and have little to recommend them. Even when the mechanism is such that a whole series of alphabets can be brought into play, if the encipherment is monoalphabetic for a succession of 20 or more letters before the alphabet changes, the degree of cryptographic security is relatively low, especially if the various alphabets are interrelated as a result of their derivation from a limited number of primary components.

150. Machines Affording Polyalphabetic Substitution

a. In recent years there have been placed upon the commercial market several cipher machines of more than ordinary interest, but they cannot be described here in detail. In some of them the number of secondary alphabets is quite limited, but the method of their employment, or rather the manner in which the mechanism operates to bring the cipher alphabets into play is so ingenious that the solution of cryptograms prepared by means of the machine is exceedingly difficult. This point should be clearly recognized and understood: *other things being equal, the manner*

REF ID:A56932

of shifting about or varying the cipher alphabets contributes more to cryptographic security than does the number of alphabets involved, or their type. For example, it is quite possible to employ 26 direct-standard alphabets in such an irregular sequence as to yield greater security than is afforded by the use of 1,000 or more mixed alphabets in a regular or an easily-ascertained method. The importance of this point is not generally recognized by inventors.

b. One of the serious limitations upon the development of good cipher machines is that the number of letters in our alphabet, 26, does not lend itself well to mechanical or mathematical manipulation, because it has but the factors 1, 2, and 13; nor is it a perfect square. If the alphabet consisted of 25, 27, or 36 characters, much more could be done. The addition of figures or symbols to the 26-letter alphabet introduces the serious practical difficulty that the cryptograms will contain characters other than letters and the cost of transmitting intermixtures of letters, figures, and symbols by Morse telegraphy is prohibitive. Subterfuges of one sort or another, employed to circumvent this difficulty, are usually impractical and expensive.

151. The Converter M–209

a. This machine, widely used for low-echelon U. S. Army communications, is a small, compact, hand-operated, tape-printing, mechanical cipher machine, weighing 6 pounds, with dimensions 7¼" x 5$^{7}/_{16}$" x 3½". The cryptographic principle of this machine embodies polyalphabetic substitution, employing a complex mechanical arrangement to generate a long running key which is used in conjunction with reversed standard alphabets for the primary components. Despite the period of 101,405,850 before the keying cycle repeats, nevertheless a high degree of security can be imparted to messages enciphered by means of this converter *only* if the machine is properly used according to authorized instructions and if the messages are drafted with proper regard for security.

b. Space does not permit the inclusion of details of operation, etc., of this machine. However, full instructions as to its use, maintenance, and repair will be found in TM 11–380, "Converter M–209, M–209–A, M–209–B (Cipher)".

152. Advantages and Disadvantages of Cipher Machines

a. The principles underlying the various machines which have thus far been developed are so diverse and complex that no description of them can be undertaken in this text. However, a few remarks of a general character, dealing with the advantages and disadvantages of cipher machines in military communications today, are deemed pertinent.

REF ID:A56932

b. Until a few years ago, code methods were predominant in military cryptography within the United States Army but the reverse is now the case. This important change has been the result of advances made within comparatively recent years in the design and construction of cryptographic systems and apparatus. It may be useful to compare code methods in general with methods based upon cipher devices and cipher machines in general to note the advantages and disadvantages of each category of methods.

c. (1) When designed for keyboard operation and equipped with a standard typewriter keyboard, cipher machines afford much more speed in encipherment and decipherment than do any "hand-operated" cryptographic methods, including codes and certain types of cipher devices. Comparative speed tests gave the following data recently:

Number of groups or words per minute

Method*	Cryptographing	Decryptographing
1	4.04 (4-letter or 4-figure groups)	6.00
2	1.94 (4-letter or 4-figure groups)	2.26
3	1.75 (5-letter groups)	1.78
4	2.74 (5-letter groups)	3.98
5	3.14 (5-letter groups)	3.54
6	30.00 (5-letter groups)	25.00

*Method 1—A 2-part code of 6,000 groups unenciphered.
Method 2—The same code enciphered by a secure system.
Method 3—The obsolete U. S. Army Cipher Device, Type M–94.
Method 4—A small electrical cryptographic machine giving lamp indications but not provided with a typewriter keyboard.
Method 5—The Converter, M–209.
Method 6—An electrical cryptographic machine producing a printed record and provided with a keyboard.

(2) When properly designed, cipher machines and certain types of "hand-operated" cryptographs afford greater guarantees of cryptographic security than do code methods or hand-operated "pencil and paper" cipher systems, because machines can accurately, speedily, and tirelessly perform far more complex cryptographic operations than can possibly be performed even by the most skillful cryptographers working with code books and cipher tables, or with hand-operated cipher systems.

(3) Though the initial cost of a cipher machine may compare unfavorably with the initial cost of a code book, the over-all cost of maintaining cryptographic security by means of cipher machines is probably less than that in the case of code systems. Good machines designed by technically qualified experts afford a multiplicity of keying arrangements; once distributed there

REF ID:A56932

is no necessity for recalling "old editions" and substituting "new editions," as is the case with code books. Therefore, the labor costs incident to the necessity for repeated preparation, printing, and distribution of code books, together with the labor costs incident to the necessity for repeated accounting operations, correspondence exchanges relative to issue, receipt, etc., in the end overbalance the higher initial cost of cipher machines. In this connection it should be stated that merely the cost of printing an edition of 200 copies of a large 2-part code is well over $25,000. This does not include the cost of the labor involved in the compilation of the code, nor of that involved in preparing, printing, and binding cipher tables for superencipherment, etc.

(4) The security of a cryptographic system involving the use of a properly designed cipher device or cipher machine is not wholly dissipated by the capture or compromise of the machine or device itself, as is the case with a code book.

(5) On the other hand, it must be admitted that, as a general rule, the solution of a very few cryptograms by long and laborious cryptanalysis makes it possible, in the case of a cipher machine, to decryptograph more or less readily many or all other cryptograms enciphered by the same machine with the same (or in certain cases) different "settings," keys, or elements; whereas in the case of a large 2-part code the solution of a few code messages can hardly be accomplished at all, and practical analysis of the code must await the accumulation of a large amount of traffic. Even should the plain text of one or two code messages be obtained by theft or capture, this would not permit the prompt decoding of subsequent messages in the same code; whereas this may be possible in the case of cipher messages.

(6) Again, cipher machines are, as a rule, complicated and delicate mechanisms. They require considerable technical skill for their proper operation by cryptographic clerks, skill which may not always be possessed by such personnel. What is perhaps more important, complicated cipher machines require the skill and services of special personnel for their proper maintenance and repair. They usually require electric current for operation, which may not always be available.

(7) If the cipher machine employed is at all complicated to set up for enciphering and deciphering, errors are easy to make and sometimes call for costly or laborious exchanges of service messages relative to their correction. However, this may be a doubtful point because complex superenciphered code is just as subject to errors as is a complex cipher machine.

REF ID:A56932

(8) As regards administrative communications, cipher cannot compete with code from the point of view of condensation or abbreviation. A cipher message is always at least as long as the original plain-text message, whereas a code message prepared by means of a large code specially compiled to give a high degree of condensation is usually much shorter than the equivalent original plain-text message. This arises, of course, from the fact that in well-constructed code books single groups of 4 or 5 characters may represent long phrases or even whole sentences.

(9) As a rule, cipher devices or machines cannot readily be operated under all sorts of weather conditions. In very damp or in rainy climates, machinery failures are quite common, and it is difficult to keep delicate machines in regular service. Moreover, in hot, humid climates no machines can long survive the disastrous corrosive effects of moisture, vegetable growths, etc., whereas printed matter is hardly affected by these elements. Finally, under field conditions, while a code book can be manipulated outdoors in all sorts of weather, in rain, sleet, or snow, in high altitudes where the temperature is very low, or in the tropics where it is very hot and humid, a cipher machine, especially if electrical, often cannot be operated with success for more than a few minutes or, at most, a few hours.

REF ID:A56932

CHAPTER 12
CODE SYSTEMS

Section I. GENERAL

153. General

a. Chapter 4 was devoted to a general consideration of code systems and enciphered code. It was there indicated that code systems are systems of substitution where the elements of the substitutive process, comprising letters, syllables, words, phrases, and sentences, are so numerous that it is impossible to memorize them or to reconstruct them at will when necessary, so that printed books containing these elements and their code equivalents must be at hand in order to cryptograph or decryptograph messages. The various types of code groups were indicated, together with methods for their construction by means of permutation tables. One-part and two-part codes were briefly discussed. Finally, a few words were added for the purpose of indicating various types of enciphering code for greater cryptographic security.

b. Practical cryptography must take cognizance of the fact that the texts of governmental as well as commercial and social telegrams must conform to certain standard forms and practices. A subsequent text will go into these matters but at this moment it is only necessary to indicate that international telegraph regulations in the past have exercised an important influence upon the structure of code groups and upon the selection of cryptographic systems for their encipherment.

c. In the subsequent paragraphs, when reference is made to ***numerical code groups,*** or ***number-code groups,*** or ***figure-code groups,*** it will be understood that the code groups are composed of digits; when reference is made to ***alphabetical code groups,*** or ***letter-code groups,*** or ***letter groups,*** it will be understood that the code groups are composed of letters of the alphabet; and when reference is made to ***mixed code groups,*** or ***mixed groups,*** it will be understood that the code groups are composed of intermixtures of letters and digits.

154. Intermixtures of Code-Text and Other Kinds of Text

a. Only in commercial code messages is the practice of mixing plain text and code text common in modern communications. In governmental code messages, military, naval, or diplomatic, such intermixtures are today so rare that their presence in telegrams indicates abysmal ignorance

REF ID:A56932

of some of the fundamental rules of cryptographic security. Because the plain-text words give definite clues to the meaning of the adjacent code groups, even though the former may apparently convey no intelligibility in themselves (such words as *and, but, by, comma, for, in, period, stop, that, the,* etc.), their presence constitutes a fatal danger, and no cryptographer who is aware of this danger will countenance such intermixtures.

b. It often happens that correspondents employ a code which makes no provision for encoding proper names or unusual words not included in the vocabulary of the code book. Rather than leave the unencodable text in plain language in the message, *since its appearance will surely lead to clues to unauthorized reading of the message,* the correspondents encipher such words and proper names by means of any prearranged cipher system. Also, in some cases, when the code is limited in its vocabulary and the various inflections of words are not represented, the correspondents may suffix the proper inflections ("ed," "ing," "tion," etc.) in cipher. This procedure, however, is not to be recommended, because it considerably reduces the cryptographic security of the whole system.

c. Sometimes correspondents make use of two or more codes within the same message. This is occasionally the case when they are making use of a general or commercial code which does not have all the special expressions necessary for their business, the latter expressions being contained in a small private code. Sometimes, however, the intermixture of code text from several codes is done for the purposes of secrecy, though it is, as a rule, a rather poor subterfuge.

Section II. ENCIPHERED CODE

155. General

a. The purposes of enciphering code have already been explained together with brief indications of methods. The superimposition of a good cipher system upon the code text of a message is a safe and practical method of cryptography for governmental use, where more rapid machine methods are not available.

b. In the subsequent paragraphs, for brevity and ease in reference, the term *placode*[12] will be employed to designate the actual or unenciphered code groups representing the plain-text elements; the term is derived by telescoping the words *plain* and *code.* On the other hand, the term *encicode*[12] will be employed to designate the final product of the superencipherment; it is likewise derived by telescoping the words *enciphered* and *code.*

[12] Pronounced "play-code" and "en-sigh'-code."

REF ID:A56932

c. The terms *superenciphered code, superencipherment,* or (British) *reciphered code* and *recipherment* all apply to code text which undergoes a subsequent process of encipherment.

d. The terms *indicator system* and *indicator* are very important in connection with all cryptographic procedures but especially so in connection with enciphering systems as applied to code. The indicator gives information relative to the proper tables to use, or the proper point to begin in such tables, etc. Further information in this regard will be given in subsequent paragraphs.

156. General Types of Methods of Superencipherment

Both transposition and substitution methods may be applied to superencipher code. There are arithmetical methods which at first glance appear to constitute a third category of superencipherment methods since they involve mathematical processes apparently resembling neither transposition nor substitution. However, deeper study will lead to the conclusion that these arithmetical methods are substitutive in character.

157. Transposition Methods

a. Transposition methods wherein whole code groups or series of them are shifted about according to some key are not frequently encountered. Transposition methods applied strictly within the code groups, by rearrainging or shifting about the letters or figures composing them, have been used to a limited extent for a number of years. Prior to January 1, 1934, transposition processes for producing encicode messages, that is, for superenciphering code, were practically never employed in commercial or governmental practice because they destroyed the regular vowel-consonant structure of code groups so that they no longer conformed to the requirements of the international telegraph regulations referred to in paragraph 153*b*. However, the restrictions in this respect were lifted on the date indicated and it may be expected that transposition processes for superenciphering code will be encountered much more frequently than in the past.

b. One of the most commonly used transposition methods for this purpose is simple keyed-columnar transposition, either with special matrices, designs, or forms having nulls and blanks, or without these features. The system as a whole, however, is very subject to error and requires high-grade personnel for its practical operation. It is, of course, wholly unsuited for practical military usage, though it can be employed for other purposes. Solution of such a system if well constructed is a very difficult matter, especially if the basic code book is not known,

REF ID:A56932

158. Substitution Methods

a. GENERAL. All of the methods of substitution applicable in the case of cipher systems are available for use in superenciphering code.

b. MONOALPHABETIC METHODS. It is, of course, easy to draw up one or more single-mixed alphabets. When the code book is in possession of the enemy cryptanalysts and the original or placode groups are therefore at hand, this method does not yield any security, for reasons not necessary here to indicate. Even when the actual code book is not known, but it is known that it is one of a set of commerical codes having groups of the 2-letter difference type, the reconstruction of the cipher alphabets is not difficult.

c. POLYALPHABETIC METHODS.

(1) A very simple polyalphabetic method is to have 5 alphabets which are used in succession; or there may be a series of sets of 5 alphabets, the individual set to be used being determined by indicators inserted in the message itself.

(2) Any sort of polyalphabetic method may be used. For example, the repeating-key method, the running or continuous-key method, the interrupted-key method, etc., can be applied. Digraphic methods may also be used; also, combinations of digraphic and monographic methods are frequent.

(3) Tables of various sorts are often employed. For example, using a table applicable to code groups of 5 figures, a table giving pronounceable combinations of letters for the combinations of digits may result in converting a group such as 75152 into the letter group KOBAL. Tables for substituting combinations of letters into other combinations of letters are, of course, equally feasible. The substitution may be strictly digraphic, combining two 5-letter or 5-figure groups into a series of 10 digraphs; or it may be a combination of trigraphic and digraphic substitution, each 5-character group being split up into a 3-character and a 2-character combination. Other combinations are, of course, also possible.

(4) In all the foregoing methods the chief objection is that the advantage of the 2-letter differential feature is more or less dissipated by the encipherment, but this is true of every substitutive method that is superimposed on code.

(5) The disadvantage referred to in the preceding subparagraph is absent in those cases in which the encipherment operates merely to substitute other code groups of the same book for the message code groups. The most common methods of this type make use of the figure-code groups, the latter being manipulated in various ways to change them and the resulting groups then

REF ID:A56932

being given their letter-code equivalents. Some of these methods are explained below.

159. Arithmetical Methods

These are the most important of the various methods of superenciphering code, and must be dealt with in somewhat greater detail than the foregoing methods. There are several different types of treatment, each of which will be briefly discussed in the subsequent subparagraphs.

160. Single or Fixed Additives

a. If the code groups are numerical, the addition of an arbitrarily selected number to each code group in the code message constitutes a simple form of superencipherment. It may be varied by prearrangement between correspondents, simply by changing the fixed number as frequently as may be deemed necessary, or by some easily arranged system of change. The group of digits composing the number which is added to the placode values is commonly termed an *additive group*, or, more often, an *additive*, or sometimes simply an *adder*. In decipherment, the additive is merely removed from the received encicode groups by subtraction, leaving the placode groups, which can then be decoded by reference to the code book. Often the date or some number derivable from the date is employed as the additive but usually the number is simply an arbitrarily composed group of digits. Because the same number is employed throughout the encipherment of the entire code message, such an additive is called a *fixed additive*.

b. Methods such as the foregoing are particularly weak cryptographically if the basic code book and the code groups embody limitations in construction. For example, should it be employed in connection with a code having only 3,000 groups numbered consecutively from 0000 to 2999, then the initial digits of the groups are limited to the three digits 0, 1, and 2; the application of a fixed additive can therefore produce only three different digits as the initial digits of the encicode text. This phenomenon would, of course, soon lead to the determination of the initial digits of the placode groups.

c. One rather simple scheme involving the use of fixed additives in the case of codes having alphabetical as well as numerical code groups is to apply the fixed additive to the numerical code groups representing the plain-text words or phrases and then take the alphabetical code groups corresponding to the sums as the final encicode groups. In codes of this type the additives may be rather large numbers and the process of finding the alphabetical code groups corresponding to the sums is very easy. But in codes wherein only alphabetical code groups are listed, that is, no figure-code or numerical groups are also given, the additives employed must naturally be rather small numbers. It would be extremely

REF ID:A56932

laborious to count 573 groups forward, for example. In cases such as these additives limited to numbers from 1 to 20 or 30 are common.

d. (1) Instead of *adding* a fixed number in encipherment, the latter may be subtracted, in which case, in decipherment, the fixed number must be added to the encicode groups as received. Such a group may be termed a *subtractive group,* or *subtractor,* because subtraction is the process used in encipherment; in decipherment the group becomes, of course, an additive.

(2) Addition and subtraction of a fixed numerical group may be alternated within the same message, according to some simple subsidiary key; for example, a series of additive groups corresponding to the keyword BAD might, by prearrangement, consist of the numbers 200, 100, 400. These might be used in repetitive manner. Or the correspondents might agree to use these key numbers alternatively in additive and subtractive manner, such as +200, −100, +400, −200, +100, −400, +200, −100, etc.

e. Addition without "carrying," or *noncarrying addition,* is just as simple as *normal addition,* that is, addition with "carrying"; and subtraction without "borrowing," or *nonborrowing subtraction,* is just as simple as *normal subtraction,* that is, subtraction with "borrowing." It is merely necessary that the correspondents agree in advance on this point and apply the process consistently throughout a message. In practice, however, it is more common to perform these processes without "carrying" or "borrowing," *so that the operations can be performed from left to right as in normal writing.* Following is an example which will make the matter clear.

Example A

(a) Example of *"noncarrying" addition* in encipherment:

(1) Placode	5517	3082	9015	6710	9541
(2) Fixed group for addition	5678	5678	5678	5678	5678
(3) Encicode	0185	8650	4683	1388	4119

(b) In decipherment, *"nonborrowing" subtraction* is applied:

(1) Encicode	0185	8650	4683	1388	4119
(2) Fixed group for subtraction	5678	5678	5678	5678	5678
(3) Placode	5517	3082	9015	6710	9541

(c) Note that in the *decipherment* process the *encicode* serves as the *minuend,* the additive used in the encipherment serves as the *subtrahend,* and the placode is the *remainder.*

f. In the foregoing example the additive remains the same throughout the superencipherment but it is obvious that this is only the simplest sort of an arrangement. A *series of different additives* may readily be employed, as will be explained later.

REF ID:A56932

g. (1) *Cryptographic procedure.* It is, however, possible to make the cryptographic procedure the same in both encipherment and decipherment, by proper changes in method. *They can both be made either additive or subtractive in nature, thus requiring the learning of but a single process.* Two methods will be explained below.

(2) *Both processes additive.* If in encipherment an additive process is used, and if in decipherment the *complement* of the additive employed in encipherment is then *added* to the encicode groups, the decipherment also becomes an additive process. For example, the complement of the group 5678, on a basis of 10, is 5432. Note the following:

Example B

(a) Example of "noncarrying" addition in encipherment:

(1) Placode	5517	3082	9015	6710	9541
(2) Fixed group for addition	5678	5678	5678	5678	5678
(3) Encicode	0185	8650	4683	1388	4119

(b) In decipherment, using the complement of the additive used in encipherment, *addition* reproduces the placode:

(1) Encicode	0185	8650	4683	1388	4119
(2) Complement of fixed group	5432	5432	5432	5432	5432
(3) Placode	5517	3082	9015	6710	9541

(3) *Both processes subtractive.* By a very simple change in procedure it is possible to apply subtraction in *both* encipherment and decipherment, using the *same* numerical groups as *subtractors,* thus making it necessary to learn only one process. If the additive, instead of being in the second line of the three lines shown in the foregoing examples, is placed on the first line, and a subtraction process applied, the proper results are obtained *regardless of whether encipherment or decipherment is involved.* Note the following example:

Example C

(a) Example of "nonborrowing" subtraction in encipherment and decipherment:

(1) Fixed group	5678	5678	5678	5678	5678
(2) Placode	5517	3082	9015	6710	9541
(3) Encicode	0161	2696	6663	9968	6137

(b) Decipherment (*subtraction also*):

(1) Fixed group	5678	5678	5678	5678	5678
(2) Encicode	0161	2696	6663	9968	6137
(3) Placode	5517	3082	9015	6710	9541

REF ID:A56932

(c) Note that in the *encipherment* process the keying group serves as the *minuend*, the *placode* as the *subtrahend*, whereupon the *remainder* becomes the *encicode;* in the *decipherment* process the keying group again serves as the *minuend*, the *encicode* as the *subtrahend*, whereupon the *remainder* becomes the *placode*.

(4) *Explanation.* The explanation involves a consideration of the nature of the processes themselves when looked at from the point of view of simple algebra. Note the following, where the symble x denotes placode, y denotes the fixed group, and z denotes encicode:

In example A (a)..... $x+y=z$
Transposing..... $x=z-y$
That is..... $z-y=x$

It is seen here that y must be *subtracted* from z in order to recover x and in order that x may be a positive quantity. Thus, this method involves both addition and subtraction.

But in example C (a)..... $y-x=z$
Transposing..... $y-z=x$,

which is exactly what is done in Example C (b). Hence it is seen that in the case of this second method only subtraction is involved, *in both processes.*

h. The method illustrated in Example C is becoming more common, because of its simplicity and ease in manipulation. It is termed the *subtractor method* and the numerical groups employed as keying groups are called *subtractors.* In paragraph 162 more will be said about this method.

161. Repeating or Recurring-Key Additives and Subtractors

a. In the foregoing examples the number which was added or subtracted in encipherment was always the same but this need not, of course, be true. It is possible to employ a *sequence* of numbers for addition or subtraction, the sequence being agreed upon in advance or it may be easily derivable from a key phrase, etc. Thus, suppose the placode message is the same as in the previous examples and that the repeating key is 432809721 and that this key is employed according to the subtractor method explained in paragraph 160*g* (3). Note the following:

(a) Encipherment:

(1) Repeating key.....	4328	0972	1432	8097	2143
(2) Placode.....	5517	3082	9015	6710	9541
(3) Encicode.....	9811	7990	2427	2387	3602

(b) Decipherment:

(1) Repeating key.....	4328	0972	1432	8097	2143
(2) Encicode.....	9811	7990	2427	2387	3602
(3) Placode.....	5517	3082	9015	6710	9541

REF ID:A56932

b. It is important to note that such a key as the foregoing must be of a length that does not contain a factor in common with the length of the code groups involved in the encipherment, for if it does contain a common factor the period will be abbreviated. For example, in the foregoing case, since the repeating key contains 9 digits and the code groups 4 digits, the length of the enciphering period is 9 groups, that is, two identical placode groups must be at least 9 groups apart before they will produce identical encicode groups. But if the keying sequence were 10 digits in length this phenomenon of cyclic repetition could happen if the identical placode groups were but 5 groups apart, since the common factor 2 cuts the potential keying length in half; and if the keying sequence were 12 digits in length the period would be but 3 groups. In this connection see also paragraph 131 *c.*

162. Nonrepeating Additives and Subtractors

a. When special tables are employed as the source of the adders or subtractors for superenciphering code, a much more secure system is provided. The tables may be contained in a book or document called a *keybook,* an *additive book,* or a *subtractor book.* On each page of such a book groups of numbers are regularly disposed in rows and columns on the page. By applying identifying symbols called *indicators* to the pages, as well as to the rows and the columns on each page of the keybook, it is possible to provide for the safe superencipherment of a large volume of traffic. All correspondents must, of course, be provided with the same basic code book and the same keybook. In employing the keybook the *indicators* tell the recipient of a message what groups were used; that is, where to begin in the decipherment of the encicode. A page from a typical keybook of this sort is shown in figure 72.

b. It should be noted that whether the arbitrary numerical groups in the keybook are employed as *adders* or as *subtractors* has nothing to do with the nature of the groups themselves: the latter may be used either way, provided consistency is observed and the correspondents agree as to whether the groups will be employed throughout the messages in the additive manner (in encipherment) illustrated in Example A (a) in paragraph 160*e,* or in the subtractor manner illustrated in Example C (a), in paragraph 160*g.* In figure 72 are shown two sets of 100 4-digit groups, disposed in numbered blocks each containing 10 columns and 10 rows of groups. To designate a group as the initial one to be employed in encipherment, or decipherment, it is merely necessary to give the block number, the row number and the column number of the group. For example, 0116 is the indicator for the group 8790. It is usual to take the successive groups in the normal order of reading, that is, from left to right and from the top downwards, although any other order of reading may be agreed upon between correspondents. The book from which this

Figure 72.

REF ID:A56932

example was taken consisted of 50 pages each containing 200 groups, making 10,000 in all. The groups themselves, of course, consist merely of digits selected *at random* when the keybook is in preparation.

c. Referring back to the method illustrated in Example B in paragraph 160*g* (2), in which addition is employed in both encipherment and decipherment, it was noted that in decipherment the *complement* of the additive employed in encipherment must be used in order to recover the placode. This principle serves as the basis for preparing keybooks in which half the contents are additives, the other half, their complements. By proper manipulation of indicators it is possible to use any given page of the arbitrary groups for encipherment, whereupon a specific page (containing the complements) must be used for decipherment. This method obviously requires considerable care in preparing the keybooks, so as to insure that complementary pages are present and are properly indicated; it also involves much more care to insure that the groups on complementary pages are accurate, although there are mechanical methods of preparing series of complements of this type.

d. If a keybook for an additive or a subtractor system is used *once and only once,* security of an absolute order is imparted to the messages *even if the basic code book is known to and possessed by the enemy.* It is not even necessary to use indicators except where a question may arise as to the serial order of one of two or more messages arriving at about the same time. In such a case the system is referred to as a *one-time system* and the keybook is called a *one-time pad* because the pages are usually fastened securely in the form of a tablet or pad and are destroyed as soon as it is certain that the recipient of a message has properly deciphered and decoded it. The disadvantages of such a system are two in number, both very serious. In the first place the production and distribution of the pads present very difficult problems in composition, printing, assembly of sheets, etc. For voluminous correspondence many pads are necessary and the mere question of the production, timely distribution, and proper safekeeping of the pads is a serious one. In the second place, a system such as this is suitable for *only two correspondents* and even in this case there usually must be two pads, one for incoming, the other for outgoing messages, otherwise it will occasionally or frequently happen that both correspondents will use the same series of additives or subtractors.

e. The foregoing difficulties make it desirable to modify the system so that while its security may not be absolute it can be employed by a larger number of correspondents, cutting down on the number of pads required and permitting of intercommunication among all correspondents. For such use, indicators are absolutely essential in order to facilitate the prompt decipherment of messages received from several different correspondents.

REF ID:A56932

f. The security of a scheme such as the foregoing is dependent upon the manner in which the indicators are treated in the cryptographing processes. If the indicators are given *in clear,* that is, without disguise of one sort or another, it becomes possible to study a series of encicode messages and perhaps to solve them, even without possession of the code. On the other hand, if the indicators are themselves disguised by enciphering them according to a well-designed method, the system as a whole becomes very secure and may, indeed, be made impregnable against attack for a very long time.

163. Observations on Arithmetical Methods

a. It can be perceived by this time that the foregoing arithmetical methods are, in reality, substitution methods. Where a fixed group is added or subtracted from the placode group this is easy to see. For example, if the fixed additive is 3089 and the placode group is 8752, the encicode group is 1731. This is the same as saying that a 4-alphabet system is involved, and the alphabets are as follows:

Placode.....		1	2	3	4	5	6	7	8	9	0	
Alphabet No.	1	4	5	6	7	8	9	0	1	2	3	"Cipher"
	2	1	2	3	4	5	6	7	8	9	0	
	3	9	0	1	2	3	4	5	6	7	8	
	4	0	1	2	3	4	5	6	7	8	9	

Note that merely a simple cyclic displacement of values is involved in the process, the amount of displacement being governed by the particular digit in each position of the additive group. What this amounts to, in cryptographic terms, is a four-alphabet encipherment using direct standard alphabets, where the "normal alphabet" is 1 2 3 4 5 6 7 8 9 0. The process could be made more difficult by employing "mixed alphabets" of course, but then the feature of speed, which is now possible (in view of early training in addition, whereby the mental arithmetic involved becomes second nature), would be lost, since constant reference would have to be made to enciphering and deciphering tables.

b. It becomes clear that when a series of different additives or subtractors is used, as when a keybook is employed, then the number of alphabets involved corresponds to the number of digits employed. Thus, despite the fact that the encipherment process is here one that involves merely the numerical equivalents of direct standard alphabets, the system can have great cryptographic security, depending upon (1) how long the keying sequence is, that is, the number of groups comprising the additive or subtractor series; (2) the composition of this keying sequence, that is, whether it consists of random digits or is systematic in its construction; and (3) whether this sequence or parts of it are used only once or several times. The last-mentioned factor is the most

REF ID:A56932

important of the three, for if the keying sequence or parts of it are used but once or a very limited number of times, say 2 or 3, its recovery by cryptanalytic processes is difficult or impossible and therefore even if the sequence is systematic in its construction this fact might not become known. However, as a rule the additives or subtractors are merely digits selected by a purely random means, such as drawing them out of a box, or equivalent means. The length of the sequence is guided only by the amount of traffic to be superenciphered; for a voluminous traffic, keybooks containing thousands of groups are necessary, even with a good indicator system, and even then the books must be changed at frequent intervals.

c. Arithmetical methods are favored above most other methods of superencipherment because of their simplicity and relatively better speed of operation than in the case of alphabetical methods. The speed factor is, of course, attributable to the fact that practically everybody can add (or subtract) rapidly and accurately when single digits are involved, and although very similar processes could be applied in cryptographic processes involving letters of the alphabet, the operations of addition or subtraction would proceed very much more slowly because early training does not devote any time to arithmetical processes involving letters. For example, every child learns that "8 plus 5 equals 13" but none learns that "H plus E equals M."

d. However, these arithmetical methods have two serious disadvantages. First, there is the disadvantage that the final encicode text is composed of numbers. The latter are not only more subject to errors in telegraphic handling than are letters, but also it is more difficult to correct garbled groups when figures are involved than when letters are involved. These disadvantages are, it must be admitted, more serious in American practice, when emphasis in training is laid upon the telegraphic transmission of letters and not figures, than they are in other practices; they may not hold in regard to countries where the emphasis in training is in the other direction, figures being preferred to letters. Second, the physical procedures involved in the preparation, reproduction, distribution, and accounting of the necessary keybooks of adders or subtractors are tedious, costly, and time consuming. Where provision must be made for voluminous intercommunication among many units and for relatively long periods of time, these matters constitute a difficult if not impossible problem for the compiling agency.

Preface

ATP 2-22.9 establishes a common understanding, foundational concepts, and methods of use for Army open-source intelligence (OSINT). ATP 2-22.9 highlights the characterization of OSINT as an intelligence discipline, its interrelationship with other intelligence disciplines, and its applicability to unified land operations.

This Army techniques publication—

- Provides fundamental principles and terminology for Army units that conduct OSINT exploitation.
- Discusses tactics, techniques, and procedures (TTP) for Army units that conduct OSINT exploitation.
- Provides a catalyst for renewing and emphasizing Army awareness of the value of publicly available information and open sources.
- Establishes a common understanding of OSINT.
- Develops systematic approaches to plan, prepare, collect, and produce intelligence from publicly available information from open sources.

The target audience for this Army techniques publication is Army units at the division level and below conducting OSINT exploitation.

Defined terms are identified in the text. Definitions for which this publication is the proponent are printed in boldface. These terms and their definitions will be incorporated into the next revision of FM 1-02. For other definitions in the text, the term is italicized, and the number of the proponent publication follows the definition. Terms for which this publication is the proponent are indicated with an asterisk in the glossary.

"OSINT personnel" applies to intelligence and nonintelligence Active Army, Army National Guard/Army National Guard of the United States, and U.S. Army Reserve personnel who engage in missions involving publicly available information and open sources.

AR 381-10 defines a *U.S. person* as—

- A U.S. citizen.
- A U.S. permanent resident alien.
- An unincorporated association substantially composed of U.S. citizens or permanent resident aliens.
- A corporation or subsidiary incorporated in the United States that is not directed or controlled by a foreign government.

The following are presumed to be *non-U.S. persons*:

- A person or organization outside of the United States.
- A person not a citizen or permanent resident alien of the United States.

The use or mention of the name of any commercial or private organization or its associated trademark or services by the Army does not express or imply an endorsement of the sponsor or its products and services by the Army.

This publication applies to the Active Army, the Army National Guard/Army National Guard of the United States, and the U.S. Army Reserve unless otherwise stated.

Headquarters, U.S. Army Training and Doctrine Command, is the proponent for this publication. The preparing agency is the U.S. Army Intelligence Center of Excellence (USAICoE), Fort Huachuca, AZ. Send written comments and recommendations on DA Form 2028 (Recommended Changes to Publications and Blank Forms) directly to: Commander, USAICoE, ATTN: ATZS-CDI-D (ATP 2-22.9), 550 Cibeque Street, Fort Huachuca, AZ 85613-7017.

Introduction

Since before the advent of the satellite and other advanced technological means of gathering information, military professionals have planned, prepared, collected, and produced intelligence from publicly available information and open sources to gain knowledge and understanding of foreign lands, peoples, potential threats, and armies.

Open sources possess much of the information needed to understand the physical and human factors of the operational environment of unified land operations. Physical and human factors of a given operational environment can be addressed utilizing publicly available information to satisfy information and intelligence requirements and provide increased situational awareness interrelated with the application of technical or classified resources.

The world is being reinvented by open sources. Publicly available information can be used by a variety of individuals to expand a broad spectrum of objectives. The significance and relevance of open-source intelligence (OSINT) serve as an economy of force, provide an additional leverage capability, and cue technical or classified assets to refine and validate both information and intelligence.

As an intelligence discipline, OSINT is judged by its contribution to the intelligence warfighting function in support of other warfighting functions and unified land operations.

Chapter 1

Open-Source Intelligence (OSINT) Fundamentals

Pioneer and reformative directives led to the passing of legislation that affected the U.S. intelligence community and its application of publicly available information. The National Security Act of 1992 began the reformation of the U.S. intelligence community resulting in the establishment of the Open Source Office and subsequently the Director of National Intelligence (DNI) Open Source Center (OSC) in 2005. This chapter describes the fundamentals of open-source intelligence (OSINT).

DEFINITION AND TERMS

1-1. *Open-source intelligence* is the intelligence discipline that pertains to intelligence produced from publicly available information that is collected, exploited, and disseminated in a timely manner to an appropriate audience for the purpose of addressing a specific intelligence and information requirement (FM 2-0). OSINT also applies to the intelligence produced by that discipline.

1-2. OSINT is also intelligence developed from the overt collection and analysis of publicly available and open-source information not under the direct control of the U.S. Government. OSINT is derived from the systematic collection, processing, and analysis of publicly available, relevant information in response to intelligence requirements. Two important related terms are open source and publicly available information:

- **Open source** is any person or group that provides information without the expectation of privacy—the information, the relationship, or both is not protected against public disclosure. Open-source information can be publicly available but not all publicly available information is open source. Open sources refer to publicly available information medium and are not limited to physical persons.
- **Publicly available information** is data, facts, instructions, or other material published or broadcast for general public consumption; available on request to a member of the general public; lawfully seen or heard by any casual observer; or made available at a meeting open to the general public.

***Note*.** All OSINT operations conducted by intelligence personnel must comply with the legal restrictions as outlined in Executive Order (EO) 12333, DOD 5240.1-R, DODD 3115.12, JP 2-0, and AR 381-10.

1-3. OSINT collection is normally accomplished through monitoring, data-mining, and research. Open-source production supports all-source intelligence and the continuing activities of the intelligence process (generate intelligence knowledge, analyze, assess, and disseminate), as prescribed in FM 2-0. Like other intelligence disciplines, OSINT is developed based on the commander's intelligence requirements.

CHARACTERISTICS

1-4. The following characteristics address the role of OSINT in unified land operations:

- **Provides the foundation.** Open-source information provides the majority of the necessary background information on any area of operations (AO). This foundation is obtained through

open-source media components that provide worldview awareness of international events and perceptions of non-U.S. societies. This foundation is an essential part of the continuing activity of *generate intelligence knowledge*.

- **Answers requirements.** The availability, depth, and range of publicly available information enables organizations to satisfy intelligence and information requirements without the use or support of specialized human or technical means of collection.
- **Enhances collection.** Open-source research supports surveillance and reconnaissance activities by answering intelligence and information requirements. It also provides information (such as biographies, cultural information, geospatial information, and technical data) that enhances and uses more technical means of collection.
- **Enhances production.** As part of a multidiscipline intelligence effort, the use and integration of publicly available information and open sources ensure commanders have the benefit of all sources of available information to make informative decisions.

THE INTELLIGENCE WARFIGHTING FUNCTION

1-5. The intelligence warfighting function is composed of four distinct Army tactical tasks (ARTs):

- Intelligence support to force generation (ART 2.1).
- Support to situational understanding (ART 2.2).
- Perform intelligence, surveillance, and reconnaissance (ART 2.3).
- Support to targeting and information superiority (ART 2.4).

1-6. The *intelligence warfighting function* is the related tasks and systems that facilitate understanding of the operational environment, enemy, terrain, weather, and civil considerations (FM 1-02). As a continuous process, the intelligence warfighting function involves analyzing information from all sources and conducting operations to develop the situation. OSINT supports each of these ARTs.

1-7. Publicly available information is used to—

- Support situational understanding of the threat and operational environment.
- Obtain information about threat characteristics, terrain, weather, and civil considerations.
- Generate intelligence knowledge before receipt of mission to provide relevant knowledge of the operational environment.
- Rapidly provide succinct answers to satisfy the commander's intelligence requirements during intelligence overwatch.
- Develop a baseline of knowledge and understanding concerning potential threat actions or intentions within specific operational environments in support of the commander's ongoing intelligence requirements.
- Generate intelligence knowledge as the basis for Army integrating functions such as intelligence preparation of the battlefield (IPB). IPB is designed to support the staff estimate and the military decisionmaking process (MDMP). Most intelligence requirements are generated as a result of the IPB process and its interrelation with MDMP.
- Support situation development—a process for analyzing information and producing current intelligence concerning portions of the mission variables of enemy, terrain and weather, and civil considerations within the AO before and during operations (see FM 2-0). Situation development—
  - Assists the G-2/S-2 in determining threat intentions and objectives.
  - Confirms or denies courses of action (COAs).
  - Provides an estimate of threat combat effectiveness.
- Support information collection. Planning requirements and assessing collection analyzes information requirements and intelligence gaps and assists in determining which asset or combination of assets are to be used to satisfy the requirements.

1-8. For more detailed information on the intelligence warfighting function, see FM 2-0. For examples of how OSINT is used to support other intelligence disciplines and operational tasks, see appendix D.

THE INTELLIGENCE PROCESS

1-9. The intelligence process consists of four steps (plan, prepare, collect, and produce) and four continuing activities (analyze, generate intelligence knowledge, assess, and disseminate). Just as the activities of the operations process (plan, prepare, execute, and assess) overlap and recur as the mission demands, so do the steps of the intelligence process. The continuing activities occur continuously throughout the intelligence process and are guided by the commander's input.

1-10. The four continuing activities plus the commander's input drive, shape, and develop the intelligence process. The intelligence process provides a common model for intelligence professionals to use to guide their thoughts, discussions, plans, and assessments. The intelligence process results in knowledge and products about the threat, terrain and weather, and civil considerations.

1-11. OSINT enhances and supports the intelligence process and enables the operations process, as described in FM 2-0. The intelligence process enables the systematic execution of Army OSINT exploitation, as well as the integration with various organizations (such as joint, interagency, intergovernmental, and multinational). Figure 1-1 illustrates the intelligence process. (For more information on the intelligence process, see FM 2-0.)

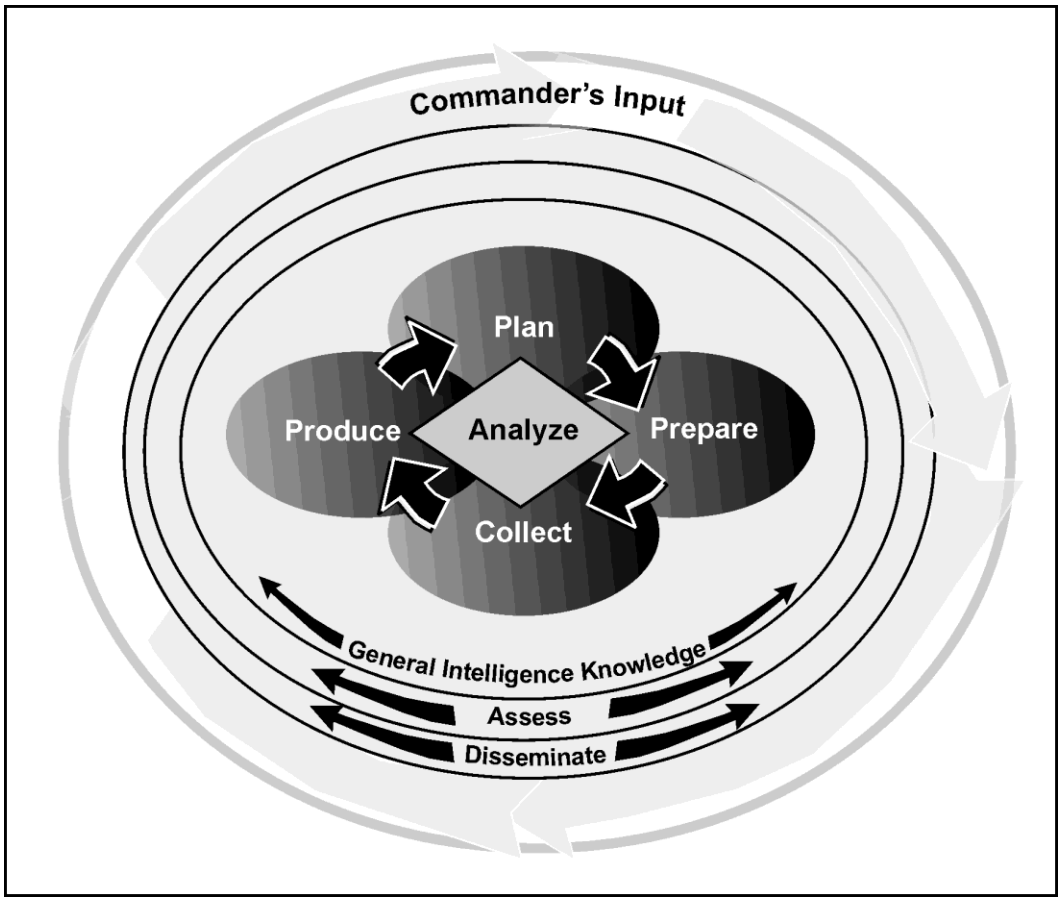

Figure 1-1. The intelligence process

THE PLANNING REQUIREMENTS AND ASSESSING COLLECTION PROCESS

1-12. Information collection informs decisionmaking for the commander and enables the application of combat power and assessment of its effects. *Information collection* is an activity that synchronizes and integrates the planning and operation of sensors, assets, as well as the processing, exploitation, and dissemination of systems in direct support of current and future operations (FM 3-55). This is an integrated intelligence and operations function. For Army forces, this activity is a combined arms operation that focuses on priority intelligence requirements (PIRs) while answering the commander's critical information requirements (CCIRs).

1-13. Information collected from multiple sources and analyzed becomes intelligence that provides answers to commanders' information requirements concerning the enemy and other adversaries, climate, weather, terrain, and population. Developing these requirements is the function of information collection:

- A *commander's critical information requirement* is an information requirement identified by the commander as being critical to facilitating timely decisionmaking. The two key elements are friendly force information requirements and priority intelligence requirements (JP 3-0).
- A *priority intelligence requirement* is an intelligence requirement, stated as a priority for intelligence support, which the commander and staff need to understand the adversary or the operational environment (JP 2-0).
- A *friendly force information requirement* is information the commander and staff need to understand the status of friendly force and supporting capabilities (JP 3-0).

1-14. The *planning requirements and assessing collection* process involves six continuous, nondiscrete activities. These activities and subordinate steps are not necessarily sequential and often overlap. The planning requirements and assessing collection process supports the staff planning and operations processes throughout unified land operations.

THE MILITARY DECISIONMAKING PROCESS

1-15. Upon receipt of the mission, commanders and staffs begin the MDMP. The *military decisionmaking process* is an iterative planning methodology that integrates the activities of the commander, staff, subordinate headquarters, and other partners to understand the situation and mission; develop and compare courses of action; decide on a course of action that best accomplishes the mission; and produce an operation plan or order for execution (FM 5-0).

1-16. During the second step of the of the MDMP, mission analysis, commanders and staffs analyze the relationships among the mission variables—mission, enemy, terrain and weather, troops and support available, time available, civil considerations (METT-TC)—seeking to gain a greater understanding of the—

- Operational environment, including enemies and civil considerations.
- Desired end state of the higher headquarters.
- Mission and how it is nested with those of the higher headquarters.
- Forces and resources available to accomplish the mission and associated tasks.

1-17. Within the MDMP, OSINT assists in enabling the planning staff to update estimates and initial assessments by using publicly available information and open sources. Major intelligence contributions to mission analysis occur because of IPB. (For more information on the MDMP, see FM 5-0.)

Note. Nonintelligence staff can also research publicly available information to prepare functional area-specific estimates, papers, briefings, plans, and orders in support of the MDMP.

INTELLIGENCE PREPARATION OF THE BATTLEFIELD

1-18. *Intelligence preparation of the battlefield* is a systematic process of analyzing and visualizing the portions of the mission variables of threat, terrain, weather, and civil considerations in a specific area of interest and for a specific mission. By applying intelligence preparation of the battlefield, commanders gain the information necessary to selectively apply and maximize operational effectiveness at critical points in time and space (FM 2-01.3).

1-19. IPB was originally designed to support the MDMP and troop leading procedures, but it can also be incorporated into other problem-solving models like design and red teaming. OSINT plays a significant and integral part during IPB in satisfying intelligence and information requirements indicated during the MDMP in support of unified land operations. The indicators that can be satisfied using OSINT during IPB include but are not limited to—

- Population.
- Propaganda.
- Commodities.
- Environment.

1-20. IPB is used primarily by commanders and staffs as a guide to evaluate specific datasets in order to gain an understanding of a defined operational environment. Prior to operations, an examination of national, multination partner, joint, and higher echelon databases is required to determine if the information requested is already available. As operations commence, new intelligence and information requirements are further identified as a result of battlefield changes. Publicly available information and open sources, when produced and properly integrated in support of the all-source intelligence effort, can be used to satisfy intelligence and information requirements. (For more information on IPB and indicators, see FM 2-01.3.)

Chapter 2

Planning and Preparation of the OSINT Mission

Directly or indirectly, publicly available information and open sources form the foundation for all intelligence when conducting operations. This foundation comes from open-source media components that provide worldview awareness of international events and perceptions of non-U.S. societies. This awareness prompts commanders to visualize a plan. Planning occurs when intelligence and information requirements are identified and means are developed as to how they will be satisfied. Effective OSINT mission planning and preparation are conducted during the Army force generation (ARFORGEN) train/ready force pool to enable the ease of transition to combat operations. (See FM 7-0 for more information on ARFORGEN.)

SECTION I – PLANNING OSINT ACTIVITIES

2-1. The *plan* step of the intelligence process consists of the activities that identify pertinent information requirements and develop the means for satisfying those requirements and meeting the commander's desired end state. As an aspect of intelligence readiness, planning for OSINT exploitation begins before a unit receives an official order or tasking as part of the *generate intelligence knowledge* continuing activity of the intelligence process.

2-2. The focus of OSINT research prior to deployment is determined and directed by the commander's guidance. Sustained and proactive open-source research using basic and advanced Internet search techniques plays a critical role in understanding AOs through foundational knowledge required for unit readiness and effective planning. Research during planning for possible missions provides insight into how nontraditional military forces, foreign military forces, and transnational threats have operated in similar AOs. Prior to deployment, organizations with dedicated OSINT missions can also be resourced to satisfy intelligence and information requirements. (See appendix E.)

2-3. After a unit receives a mission, the focus of OSINT research is further refined based on the AO in which the unit operates. OSINT supports the continuous assessment of unified land operations during planning. Effective research and planning ensure commanders receive timely, relevant, and accurate intelligence and information to accomplish assigned missions and tasks. The MDMP and IPB driven by the intelligence process frame the planning of OSINT exploitation. OSINT is integrated into planning through the four steps of the IPB process:

- Define the operational environment.
- Describe environmental effects on operations.
- Evaluate the threat.
- Determine threat COAs.

DEFINE THE OPERATIONAL ENVIRONMENT

2-4. When assessing the conditions, circumstances, and influences in the AO and area of interest, the intelligence staff examines all characteristics of the operational environment. There are preexisting publicly available inputs that can be used to identify significant variables when analyzing the terrain, weather, threat, and

civil considerations. At the end of step one of the IPB process, publicly available information and open sources can be used to support the development of the AO assessment and area of interest assessment.

DESCRIBE ENVIRONMENTAL EFFECTS ON OPERATIONS

2-5. When analyzing the environmental effects on threat and friendly operations, publicly available information and open sources can be used to describe the—

- Physical environment (terrestrial, air, maritime, space, and information domains).
- Weather.
- Civil considerations.
- Threat.

2-6. Combine the evaluation of the effects of terrain, weather, and civil considerations into a product that best suits the commander's requirements. At the end of the second step of IPB, publicly available information and open sources can be used to better inform the commander of possible threat COAs and products and assessments to support the remainder of the IPB process.

EVALUATE THE THREAT

2-7. Step three of the IPB process is to evaluate each of the significant threats in the AO. If the staff fails to determine all the threat factions involved or their capabilities or equipment, or to understand their doctrine and tactics, techniques, and procedures (TTP), as well as their history, the staff will lack the intelligence needed for planning. At the end of step three of IPB, publicly available information and open sources can provide the majority of the information required to identify threat characteristics, as well as provide possible information needed to update threat models.

DETERMINE THREAT COURSES OF ACTION

2-8. Step four of the IPB process is to identify, develop, and determine likely threat COAs that can influence accomplishment of the friendly mission. The end state of step four is to replicate the set of COAs available to the threat commander and to identify those areas and activities that, when observed, discern which COA the threat commander has chosen. At the end of step four of IPB, publicly available information and open sources can be used to determine indicators adopted by the threat commander.

SECTION II – PREPARATION OF OSINT ACTIVITIES

2-9. The reliance on classified databases has often left Soldiers uninformed and ill-prepared to capitalize on the huge reservoir of unclassified information from publicly available information and open sources, as the following quote describes:

> *OSINT was fairly new to us and once the term was understood we placed a signals intelligence analyst in charge of OSINT. At the tactical level, it seemed to be effective after the fact. There were three successful attacks against coalition forces aircraft in a specific area. We couldn't figure out the "how" and 5Ws [who, what, when, where, why] but our OSINT analyst found a downed aircraft video on the Internet that helped us identify the ingress and egress routes used during the attack that led to a "no fly" area and successful area denial missions in our area of operation.*
>
> All-Source Intelligence Analyst, Combat Aviation Brigade
> Operation Iraqi Freedom 2008-2009,

OSINT EXPLOITATION

2-10. When preparing to conduct OSINT exploitation, the areas primarily focused on are—

- Public speaking forums.
- Public documents.
- Public broadcasts.
- Internet Web sites.

PUBLIC SPEAKING FORUMS

2-11. Acquiring information at public speaking forums requires close coordination to ensure that any overt acquisition is integrated and synchronized with the information collection plan and does not violate laws prohibiting the unauthorized collecting of information for intelligence purposes. (See appendix A for further information on U.S. persons.)

2-12. Before gathering OSINT information at public speaking forums—

- Coordinate with key staff sections, such as the G-2X/S-2X, G-7/S-7, G-9/S-9, public affairs officer (PAO), and staff judge advocate (SJA), prior to conducting surveillance.
- Identify additional force protection personnel and equipment requirements.
- Identify the procedure for emplacement and recovery of audio and video processing equipment.

2-13. The operation order (OPORD), TTP, or unit standard operating procedures (SOPs) should describe how the unit that is tasked with the public speaking forum mission requests, allocates, and manages funds to purchase digital camera and audio recording equipment along with the computer hardware and software to play and store video-related data.

PUBLIC DOCUMENTS

2-14. Organizations within an AO conduct document collection missions. Once collected, documents are analyzed and the information is disseminated throughout the intelligence community. Before executing any OSINT exploitation related to collecting public documents, it is important to—

- Coordinate document collection, processing, and analysis activities across echelons.
- Identify the procedure to deploy, maintain, recover, and transfer hardcopy, analog, and digital media processing and communications equipment.
- Identify academic and commercial-off-the-shelf (COTS) information services that are already available for open-source acquisition, processing, and production.

2-15. The OPORD, TTP, or unit SOPs should describe how the unit requests, allocates, and manages funds for—

- Document collection and processing services.
- Purchasing books, dictionaries, images, maps, newspapers, periodicals, recorded audio and video items, computer hardware, digital cameras, and scanning equipment.
- The cost of subscribing to newspapers, periodicals, and other readable materials.

2-16. For more detailed information on public documents and document exploitation, see TC 2-91.8.

PUBLIC BROADCASTS

2-17. The DNI OSC collects, processes, and reports international and regional broadcasts. This enables deployed organizations to collect and process information from local broadcasts that are of command interest. Before exploiting OSINT related to public broadcasts, it is important to—

- Coordinate broadcast collection, processing, and production activities with those of the OSC.
- Identify the procedure to deploy, maintain, recover, and transfer radio and television digital media storage devices and content processing and communications systems.

- Identify Internet collection and processing resources to collect on television or radio station-specific Web casts.

2-18. The OPORD, unit SOPs, or TTP should describe how the unit tasked with public broadcast missions requests, allocates, and manages funds to purchase antenna and computer equipment, machine translation services or software, and subscribes to regional and international satellite radio and television broadcast service providers.

INTERNET WEB SITES

2-19. Information collected, processed, and produced from Internet Web sites supports unified land operations. Before exploiting OSINT related to Internet Web sites—

- Coordinate Internet collection, processing, and analysis activities across echelons.
- Identify the procedure to deploy, maintain, recover, and transfer computers and associated communications and data storage systems.
- Coordinate with G-6/S-6 for access to the INTELINK-U network or approved commercial Internet service providers that support open-source acquisition, processing, storage, and dissemination requirements.
- Coordinate with G-6/S-6 to develop a list of authorized U.S. and non-U.S. Internet Web sites for official government use, open-source research, and non-U.S. Internet Web sites restricted to selected authorized personnel engaged in OSINT exploitation.
- Identify academic and COTS information services that are already available for open-source information acquisition, processing, and production.

2-20. The OPORD, unit SOPs, or TTP should describe how the unit tasked with Internet research missions requests, allocates, and manages funds to purchase digitized documents, geospatial information, computer hardware and software applications, as well any subscriptions to academic and commercial online databases, newspapers, periodicals, and references.

PREPARATION CONSIDERATIONS

2-21. Preparing for OSINT exploitation also includes—

- Establishing an OSINT architecture.
- Prioritizing tasks and requests.
- Task-organizing assets.
- Deploying assets.
- Assessing completed operations.

ESTABLISHING AN OSINT ARCHITECTURE

2-22. OSINT contributes to establishing an intelligence architecture, specifically ART 2.2.2, *Establish Intelligence Architecture*. Establishing an intelligence architecture comprises complex and technical issues that include sensors, data flow, hardware, software, communications, communications security materials, network classification, technicians, database access, liaison officers, training, and funding. A well-defined and -designed intelligence architecture can offset or mitigate structural, organizational, or personnel limitations. This architecture provides the best possible understanding of the threat, terrain and weather, and civil considerations. An established OSINT architecture incorporates data flow, hardware, software, communications security components, and databases that include—

- **Conducting intelligence reach.** *Intelligence reach* is a process by which intelligence organizations proactively and rapidly access information from, receive support from, and conduct direct collaboration and information sharing with other units and agencies, both within and outside the area of operations, unconstrained by geographic proximity, echelon, or command (FM 2-0).
- **Developing and maintaining automated intelligence networks.** This task entails providing information systems that connect assets, units, echelons, agencies, and multinational partners for

intelligence, collaborative analysis and production, dissemination, and intelligence reach. It uses existing automated information systems, and, when necessary, creates operationally specific networks.

- **Establishing and maintaining access.** This task entails establishing, providing, and maintaining access to classified and unclassified programs, databases, networks, systems, and other Web-based collaborative environments for Army forces, joint forces, national agencies, and multinational organizations.
- **Creating and maintaining databases.** This task entails creating and maintaining unclassified and classified databases. Its purpose is to establish interoperable and collaborative environments for Army forces, joint forces, national agencies, and multinational organizations. This task facilitates intelligence analysis, reporting, production, dissemination, sustainment, and intelligence reach.

Operational and Technical Open-Source Databases

2-23. OSINT exploitation requires access to databases and Internet capabilities to facilitate processing, storage, retrieval, and exchange of publicly available information. These databases are resident on local area networks (LANs), the World Wide Web (WWW), and the Deep Web (see appendix C for additional information). To support unified land operations, OSINT personnel use evaluated and analyzed publicly available information and open sources to populate information databases such as—

- **Operational information databases**, which support the correlation of orders, requests, collection statuses, processing resources, and graphics.
- **Technical information databases**, which support collection operations and consist of unprocessed text, audio files, video files, translations, and transcripts.

Open-Source Collection Acquisition Requirement–Management System

2-24. The primary open-source requirements management operational information and technical information database is the Open-source Collection Acquisition Requirement-Management System (OSCAR-MS). OSCAR-MS is a Web-based service sponsored by the Office of the Assistant Deputy Director of National Intelligence for Open Source (ADDNI/OS) to provide the National Open Source Enterprise (NOSE) with an application for managing open-source collection requirements. OSCAR-MS links OSINT providers and consumers within the intelligence community down to the brigade combat team (BCT) level. Personnel at the BCT level access OSCAR-MS via the SECRET Internet Protocol Router Network (SIPRNET) in order to submit requests for information to the Department of the Army Intelligence Information Services (DA IIS) request for information portal. The goal of the OSCAR-MS is to automate and streamline ad hoc open-source collection requirements by—

- Providing useful metrics to understand OSINT requirements.
- Allowing the digital indexing and tagging of submitted and completed open-source products to be searchable in the Library of National Intelligence.
- Providing for local control of administrative data such as unit account management, local data tables, and local formats.
- Allowing simple and flexible formats that employ database auto-population.
- Using complete English instead of acronyms, computer codes, and other nonintuitive shortcuts.
- Allowing linkages between requirements, products, and evaluations.
- Enabling integration of open-source users for collaboration between agencies.
- Reducing requirement duplication through customers directly contributing to existing requirements.

2-25. For more detailed information on OSCAR-MS or to submit OSINT requirements, contact the U.S. Army Intelligence and Security Command (INSCOM) DA IIS at https://www.intelink.gov/sharepoint/default.aspx.

PRIORITIZING TASKS AND REQUESTS

2-26. The G-2/S-2 and G-3/S-3 staffs use commander guidance and primary intelligence requirements to complete the information collection plan. The plan is used to assign tasks to subordinate units or submit requests to supporting intelligence organizations to achieve the desired information collection objectives. Embodied in the information collection plan, these tasks describe how the unit—

- Requests collection and production support from joint, interagency, intergovernmental, and multinational organizations.
- Task-organizes and deploys organic, attached, and contracted collection, processing, and production assets.
- Conducts remote, split-based, or distributed collection, processing, and production.
- Requests and manages U.S. and non-U.S. linguists based on priority for support, mission-specific skills, knowledge requirements (such as language, dialect, and skill level), clearance level, and category.

2-27. When developing information collection tasks for subordinate units, the G-2/S-2 and G-3/S-3 staffs use the task and purpose construct for developing task statements to account for—

- *Who* is to execute the task?
- *What* is the task?
- *When* will the task begin?
- *Where* will the task occur?

TASK-ORGANIZING ASSETS

2-28. With the exception of the Asian Studies Detachment (ASD) that maintains an organic table of distribution and allowances (TDA) with the government of Japan in support of U.S. Pacific Command (USPACOM), the Army does not have a TDA or base table of organization and equipment for OSINT personnel or units when preparing to conduct OSINT exploitation.

DEPLOYING ASSETS

2-29. Deployment of publicly available assets—

- Supports the scheme of maneuver.
- Supports the commander's intent.
- Complies with unit SOPs.

2-30. The deployment of assets generally requires a secure position, with network connectivity to the Internet, in proximity to supporting sustainment, protection, and communications resources.

ASSESSING COMPLETED OPERATIONS

2-31. Typical guidelines used to assess operations are—

- Monitoring operations.
- Correlating and screening reports.
- Disseminating and providing a feedback mechanism.
- Cueing.

2-32. See paragraph 2-67 for an explanation of these guidelines.

SECTION III – PLANNING AND PREPARATION CONSIDERATIONS

2-33. Planning and preparation considerations when planning for OSINT exploitation include—

- Open-source reliability.
- Open-source information content credibility.
- Compliance.
- Operations security (OPSEC).
- Classification.
- Coordination.
- Deception and bias.
- Copyright and intellectual property.
- Linguist requirements.
- Machine foreign language translation (MFLT) systems.

OPEN-SOURCE RELIABILITY

2-34. The types of sources used to evaluate information are—

- Primary sources.
- Secondary sources.

2-35. A *primary source* refers to a document or physical object that was written or created during the time under study. These sources are present during an experience or time period and offer an inside view of a particular event. Primary sources—

- Are generally categorized by content.
- Is either public or private.
- Is also referred to as an original source or evidence.
- In fact, are usually fragmentary, ambiguous, and difficult to analyze. The information contained in primary sources is also subject to obsolete meanings of familiar words.

2-36. Some types of primary sources include—

- Original documents (excerpts or translations) such as diaries, constitutions, research journals, speeches, manuscripts, letters, oral interviews, news film footage, autobiographies, and official records.
- Creative works such as poetry, drama, novels, music, and art.
- Relics or artifacts such as pottery, furniture, clothing, artifacts, and buildings.
- Personal narratives and memoirs.
- Person of direct knowledge.

2-37. A *secondary source* interprets, analyzes, cites, and builds upon primary sources. Secondary sources may contain pictures, quotes, or graphics from primary sources. Some types of secondary sources include publications such as—

- Journals that interpret findings.
- Textbooks.
- Magazine articles.
- Commentaries.
- Histories.
- Criticisms.
- Encyclopedias.

Note. Primary and secondary sources are oftentimes difficult to distinguish as both are subjective in nature. Primary sources are not necessarily more of an authority or better than secondary sources. For any source, primary or secondary, it is important for OSINT personnel to evaluate the report for deception and bias.

2-38. Open-source reliability ratings range from **A** (reliable) to **F** (cannot be judged) as shown in table 2-1. A first-time source used in the creation of OSINT is given a source rating of **F**. An **F** rating does not mean the source is unreliable, but OSINT personnel have no previous experience with the source upon which to base a determination.

Table 2-1. Open-source reliability ratings

A	***Reliable***	**No doubt** of authenticity, trustworthiness, or competency; has a history of complete reliability.
B	***Usually reliable***	**Minor doubt** about authenticity, trustworthiness, or competency; has a history of valid information most of the time.
C	***Fairly reliable***	**Doubt** of authenticity, trustworthiness, or competency, but has provided valid information in the past.
D	***Not usually reliable***	**Significant doubt** about authenticity, trustworthiness, or competency, but has provided valid information in the past.
E	***Unreliable***	**Lacking** authenticity, trustworthiness, and competency; history of invalid information.
F	***Cannot be judged***	**No basis** exists for evaluating the reliability of the source.

OPEN-SOURCE INFORMATION CONTENT CREDIBILITY

2-39. Similar to open-source reliability, credibility ratings range from **one** (confirmed) to **eight** (cannot be judged) as shown in table 2-2. If the information is received from a first-time source, it is given a rating of **eight** and, like the reliability ratings scale, does not mean the information is not credible but that OSINT personnel have no means to verify the information.

Table 2-2. Open-source content credibility ratings

1	***Confirmed***	**Confirmed** by other independent sources; logical in itself; consistent with other information on the subject.
2	***Probably true***	**Not confirmed**; logical in itself; consistent with other information on the subject.
3	***Possibly true***	**Not confirmed**; reasonably logical in itself; agrees with some other information on the subject.
4	***Doubtfully true***	**Not confirmed**; possible but not logical; no other information on the subject.
5	***Improbable***	**Not confirmed**; not logical in itself; contradicted by other information on the subject.
6	***Misinformation***	**Unintentionally false**; not logical in itself; contradicted by other information on the subject; confirmed by other independent sources.
7	***Deception***	**Deliberately false**; contradicted by other information on the subject; confirmed by other independent sources.
8	***Cannot be judged***	**No basis** exists for evaluating the validity of the information.

COMPLIANCE

2-40. In accordance with EO 12333, DOD 5240.1-R, and AR 381-10, procedure 2, Army intelligence activities may collect publicly available information on U.S. persons only when it is necessary to fulfill an assigned function. (For more information on intelligence oversight, see appendix A.)

OPERATIONS SECURITY

2-41. OSINT could unintentionally provide present and future indicators of U.S. military operations. Information generally available to the public can reveal the existence of, and sometimes details about classified or sensitive information that can be used to neutralize or exploit military operations. Intelligence organizations

must determine the level of contact with open sources and the collection or acquisition technique that could affect Army operations.

CLASSIFICATION

2-42. AR 380-5 states that intelligence producers "must be wary of applying so much security that they are unable to provide a useful product to consumers." This is an appropriate warning for OSINT personnel where concern for OPSEC can undermine the ability to disseminate inherently unclassified information. Examples of unclassified information being over-classified are—

- Reported information found in a foreign newspaper.
- Message from a foreign official attending an international conference.

2-43. AR 380-5 directs that Army personnel will not apply classification or other security markings to an article or portion of an article that has appeared in a newspaper, magazine, or other public medium. Final analysis of OSINT may require additional restrictions and be deemed *controlled unclassified information* or *sensitive but unclassified information*.

COORDINATION

2-44. During planning, the G-2/S-2 and G-3/S-3 staff must ensure that OSINT missions and tasks are synchronized with the scheme of maneuver. Acquiring open-source information may compromise the operations of other intelligence disciplines or tactical units. Open-source acquisition that is not synchronized may also result in the tasking of multiple assets and the improper utilization of forces and equipment, adversely affecting the ability of nonintelligence organizations, such as civil affairs, military police, and public affairs, to accomplish assigned missions and tasks. Conversely, overt contact with an open source by nonintelligence organizations can compromise OSINT missions and tasks and lead to the loss of intelligence.

DECEPTION AND BIAS

2-45. Deception and bias is a concern in OSINT exploitation. OSINT exploitation does not normally acquire information by direct observation of activities and conditions within the AO. OSINT exploitation relies mainly on secondary sources to acquire and disseminate information. Secondary sources, such as government press offices, commercial news organizations, and nongovernmental organizations spokespersons, can intentionally or unintentionally add, delete, modify, or otherwise filter the information made to the general public. These sources may also convey one message in English with the intent to sway U.S. or international perspectives and a different non-English message for local populace consumption. It is important to know the background of open sources and the purpose of the public information in order to distinguish objectives, factual information, identify bias, or highlight deception efforts against the reader and the overall operation.

COPYRIGHT AND INTELLECTUAL PROPERTY

2-46. *Copyright* is a form of protection, for published and unpublished works, provided by Title 17, United States Code (USC), to authors of "original works of authorship," including literary, dramatic, musical, and artistic works. Intellectual property is considered any creation of the mind and includes, but is not limited to—

- Musical works and compositions.
- Artistic displays.
- Discoveries.
- Inventions.
- Words or phrases.
- Symbols and designs.

2-47. It is illegal to violate the rights provided by the copyright law to the owner of copyright. One major limitation is the doctrine of fair use, which is given a statutory basis in Section 107 of the 1976 Copyright Act. According to the U.S. Copyright Office, "fair use" of a copyrighted work for purposes such as criticism, comment, news reporting, teaching, scholarship, or research is not an infringement of copyright. The four factors in determining fair use are the—

- Purpose and character of the use.
- Nature of the copyrighted work.
- Amount and substantiality of the portion used in relation to the copyrighted work as a whole.
- Effect of the use upon the potential market for or value of the copyrighted work.

2-48. AR 27-60 prescribes policies and procedures for the acquisition, protection, transfer, patent usage, copyrights, and trademarks of intellectual property. Army policy recognizes the rights of copyright owners consistent with Army missions and worldwide commitments. OSINT personnel will not produce or distribute copyrighted works without the permission of the copyright owner unless such use is authorized under U.S. copyright law. There is also a requirement for OSINT personnel to forward to the Service SJA for approval and waiver of notice to the copyright holder, if necessary, for OPSEC. (For more information on copyright laws and applicability, see the International Copyright Relations of the United States at http://www.copyright.gov or the local SJA office.)

LINGUIST REQUIREMENTS

2-49. The ability to gather and analyze foreign materials is critical in OSINT exploitation. The effective use and employment of linguists, both civilian and military, facilitates this activity. The areas of the highest criticality of required foreign language skills and knowledge proficiency are—

- **Transcription.** Both listening and writing proficiency in the source language are essential for an accurate transcript. A transcript is extremely important when English language skills of the OSINT personnel are inadequate for authoritative or direct translation from audio or video into English text.
- **Translation.** Bilingual competence is a prerequisite for translations. Linguists must be able to—
  - Read and comprehend the source language.
  - Write comprehensibly in English.
  - Choose the equivalent expression in English that fully conveys and best matches the meaning intended in the source language.
- **Interpretation.** Bilingual competence is a prerequisite for interpretation. Linguists must be able to—
  - Hear and comprehend the source language.
  - Speak comprehensibly in English.
  - Choose the equivalent expression in English that fully conveys and best matches the meaning intended in the source language.

Note. Interpretation is a specific skill in which not all linguists are trained.

2-50. To effectively plan and employ linguists, commanders and staffs must understand the Army linguist proficiency evaluation system. Evaluation and reevalution of linguist proficiency is covered in detail in AR 11-6, chapter 5. Language testing is required for all Army personnel, in a language-dependent military occupational specialty (MOS) or Army occupational code (AOC), who have received foreign language training. Other Army personnel who have knowledge of a foreign language are encouraged to take the proficiency test and may work as linguists.

2-51. The Army uses the Defense Language Proficiency Test (DLPT) to measure the proficiency level in a specific language. The DLPT is an indication of foreign language capability, but it is not the definitive evaluation of an individual's ability to perform linguist support.

2-52. The Army uses Interagency Language Roundtable (ILR) descriptions of the proficiency levels for the skills of speaking, listening, reading, and writing a foreign language. Detailed descriptions of these levels are available at http://www.govtilr.org. The plus-level designators, shown as a "+" symbol, are used to designate when a linguist is above a base level, but not yet to the capability of the next level. The six base levels of proficiency as established by the DLPT are—

- **Level 0 (no proficiency).** The Soldier has no functional foreign language ability. Level 0+ is the minimum standard for special-forces personnel and indicates a memorized proficiency only.
- **Level 1 (elementary proficiency).** The Soldier has limited control of the foreign language skill area to meet limited practical needs and elementary foreign language requirements.
- **Level 2 (limited working proficiency).** The linguist is sufficiently skilled to be able to satisfy routine foreign language demands and limited work requirements.
- **Level 3 (general professional proficiency).** The linguist is capable of performing most general, technical, formal, and informal foreign language tasks on a practical, social, and professional level.
- **Level 4 (advanced professional proficiency).** The linguist is capable of performing advanced professional foreign language tasks fluently and accurately on all levels.
- **Level 5 (functionally native proficiency).** The linguist is functionally equivalent to an articulate and well-educated native in all foreign language skills; the linguist reflects the cultural standards of the country where the foreign language is natively spoken.

2-53. The above proficiency base levels designate proficiency in any of the four language skills—listening, reading, speaking, and writing. The DLPT only evaluates reading and listening skills (for example, 2+/3, or 3/1+). Currently, these tests do not evaluate linguists above the 3-proficiency level. The current Army standard to be considered a qualified linguist is a level 2. Oral proficiency interviews evaluate speaking proficiency and may be used to provide a listening score. These interviews may provide an evaluation all the way up to the 5-proficiency level.

2-54. Along with proficiency and fluency, OSINT personnel must consider the biases and cultural backgrounds of civilian interpreters when analyzing non-English open-source information. When planning to utilize linguists, commanders must identify requirements by category. Linguist screening categories are—

- **Category I.** Linguists must at least have advanced professional proficiency in the target language, a level 4 as measured by the ILR and general working proficiency (ILR 2+) in English. They may be locally hired or from a region outside the AO. They do not require a security clearance.
- **Category II.** Linguists are U.S. citizens granted access to a Secret clearance by the designated U.S. Government personnel security authority. They must at least have advanced professional proficiency in the target language (ILR 4) and general working proficiency (ILR 2+) in English.
- **Category III.** Linguists are U.S. citizens granted Top Secret (TS)/Sensitive Compartmented Information (SCI) or an interim TS/SCI clearance by the designated U.S. Government personnel security authority. They must meet a minimum of ILR 3 in both the target language and English.

MACHINE FOREIGN LANGUAGE TRANSLATION SYSTEMS

2-55. Developing a reliable and proficient linguist requires a great deal of time, both for training and gaining experience. This extended timeline often results in shortages of linguist personnel. To fill personnel vacancies throughout Army units and to meet language requirements and demands, MFLT systems are used. When employed properly, MFLT systems can provide an increased capability for translation in support of unified land operations.

2-56. Reliable MFLT capability exists to translate media broadcasts into English and there is readily available software to translate Internet sources into English as well. There are limited speech-to-speech (S2S) capabilities in use.

FOREIGN MEDIA MONITORING

2-57. Media monitoring systems like the BBN Broadcast Monitoring System™ (BMS™) create a continuous searchable archive of international television broadcasts. These systems automatically transcribe the real-time audio stream and translate it into English. Both the transcript and translation are searchable and synchronized to the video, providing powerful capabilities for effective retrieval and precise playback of the video based on its speech content. With this system, intelligence analysts can sift through vast collections of news content in other languages quickly and efficiently.

2-58. These systems provide real-time transcription and translation of broadcast television news, allowing English speakers to rapidly triage non-English television content, be alerted when new content that matches a profile is captured by the system, and work closely with human linguists and cultural experts to create actionable high-quality translations of extracted content.

2-59. The interface allows users to quickly search for specific spoken content in the video archive through keyword queries in English or the source language. Search terms are highlighted in the results, which show an image thumbnail, the transcript segment in the original language, and an English translation. Clicking on a result begins playback of the segment.

2-60. Users interact with the system from any personal computer (PC) or laptop via a common high-speed Internet connection. The only required client software is Microsoft® Internet Explorer and Windows Media® Player.

2-61. The BBN BMS™ continuously captures, encodes, analyzes, and stores live video streams in an automatically maintained, dynamic cache containing 30 days of recorded audio or video. As the video plays back, the system highlights the spoken words in both the original language and the translation. The transcript is enriched by highlighting the names of people, locations, and organizations, and by separating the speakers in the audio file. Users can jump to any point in the cache and begin playback.

2-62. Users can extract video segments or still photos for sharing, presentation, and collaboration. Demonstration compact discs (CDs) contain extracted segments that preserve the highlighting and synchronization of video, transcript, and translation during playback.

2-63. The BBN BMS™ currently translates—

- Modern Standard Arabic.
- Mandarin Chinese.
- Western Hemisphere Spanish.
- Persian Farsi.
- North American English.
- United Kingdom English.
- French.
- Bahasa Indonesian.
- Hindi.
- Urdu.

2-64. The BBN BMS™ does not require any hardware setup, software installation, or onsite administration or maintenance by the customer.

SPEECH-TO-SPEECH

2-65. Army and Marine units continue to attempt to integrate available COTS S2S translation devices into predeployment training and military operations while deployed. The primary tactical use for these devices has been language translation within security operations conducted in and among a general population of non-English speaking people.

SECTION IV – MANNING THE OSINT SECTION

2-66. OSINT personnel that comprise the OSINT section within the intelligence staff section can consist of both intelligence and nonintelligence individuals with the technical competence, creativity, forethought, cultural knowledge, and social awareness to exploit open sources effectively. The designation of OSINT personnel to satisfy requirements, missions, and tasks is generally identified by commanders and task-organized through organic assets (intelligence personnel, nonintelligence personnel, U.S. and non-U.S. contractor personnel, or linguists) in support of unified land operations.

OSINT SECTION DUTIES

2-67. The duties of the OSINT section are to—

- **Monitor operations.** This ensures responsiveness to the current situation and to anticipate future acquisition, processing, reporting, and synchronization requirements.
- **Correlate reports.** Reports (written, verbally, or graphically) should correlate classified reports through OSINT validation.
- **Screen reports.** Information is screened in accordance with the CCIRs and commander's guidance to ensure that pertinent and relevant information is not overlooked and the information is reduced to a workable size. Screening should encompass the elements of timeliness, completeness, and relevance to satisfy intelligence requirements.
- **Disseminate intelligence and information.** Satisfied OSINT requirements are disseminated to customers in the form of useable products and reports.
- **Cue.** Effective cueing by OSINT to more technical information collection assets, such as human intelligence (HUMINT) and counterintelligence (CI) improves the overall information collection effort by keeping organizations abreast of emerging unclassified information and opportunities as well as enabling the use of a multidiscipline approach to confirm or deny information by another information source, collection organization, or production activity.
- **Provide feedback.** An established feedback mechanism is required to the supported commander or customer on the status of intelligence and information requirements.

OSINT SECTION AT THE BRIGADE COMBAT TEAM LEVEL

2-68. Each combatant command may have a task-organized OSINT cell or section to some varying degree in scope and personnel. At the tactical level of operations, it is commonplace for commanders to create OSINT cells from organic intelligence personnel to satisfy intelligence requirements.

2-69. The following quote illustrates how task organization of organic personnel within the common ground station (CGS) can assist in satisfying intelligence and information requirements using the Nonsecure Internet Protocol Routing Network (NIPRNET) and various electronic devices, such as an amplitude modulation and frequency modulation (AM/FM) radio, video cassette recorder (VCR), and digital video disc (DVD) player, to ensure the success of their BCT to perform information collection at the tactical operations center (TOC):

With their CGS team, four to five interpreters, and a steady flow of radio, television, and newspaper reports, the open-source intelligence team produced a daily rollup with analysis. Their office consisted of one television with local and international cable, one laptop connected to the NIPRNET, AM/FM radio, and the daily newspaper. Also, the team acquired a VCR and DVD player to study confiscated propaganda and other media. They understand the importance of local reporting to the success of the BCT campaign and have made it a point to conduct thorough research on topics of local importance. Their product was studied and further analyzed by the (information collection) analysis team at the BCT TOC prior to submission to the BCT S-2 and dissemination to battalions or division.

Military Intelligence Company Commander, 3ID,
Operation Iraqi Freedom 2004—2005

2-70. As displayed in figure 2-1, personnel comprising the OSINT section at the BCT level include—

- Section leader.
- Requirements manager.
- Situation development analyst.
- Target development analyst.

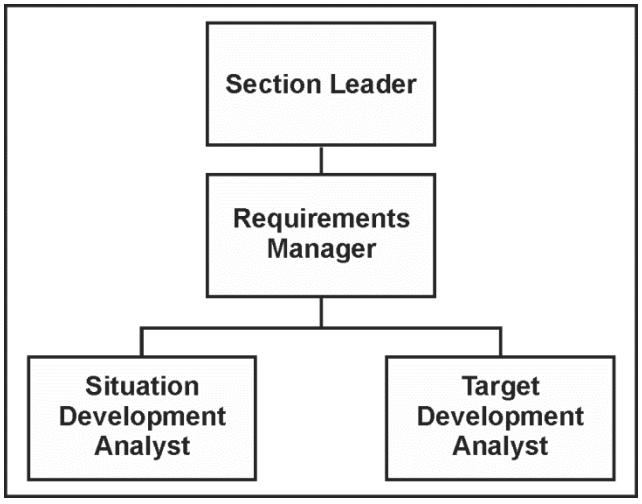

Figure 2-1. Brigade combat team's OSINT section

SECTION LEADER

2-71. The section leader—

- Is the primary liaison and coordinator with the BCT S-2.
- Provides supervisory and managerial capacity oversight.
- Sets the priority of tasks.
- Monitors ongoing intelligence support required by the BCT S-2.
- Ensures that all OSINT products are included in the planning for current and future operations.

REQUIREMENTS MANAGER

2-72. The requirements manager—

- Ensures that situation development and target development support the overall efforts of the section.
- Verifies the availability of collection assets.
- Performs quality control for situation development and target development products.
- Supervises the receipt, analysis, and dissemination of OSINT products.

SITUATION DEVELOPMENT ANALYST

2-73. The situation development analyst—

- Monitors publicly available information and open sources in order to ensure the most accurate common operational picture.
- Analyzes information and produces current intelligence about the operational environment, enemy, terrain, and civil considerations before and during operations.
- Refines information received on threat intentions, objectives, combat effectiveness, and potential missions.
- Confirms or denies threat COAs based on publicly available indicators.
- Provides information to better understand the local population in areas that include, but are not limited to—
  - Tribal affiliations.
  - Political beliefs.
  - Religious tenets.
  - Key leaders.
  - Support groups.
  - Income sources.

TARGET DEVELOPMENT ANALYST

2-74. The target development analyst—

- Identifies the components, elements, and characteristics of specific targets, both lethal and nonlethal.
- Identifies civil and other non-target considerations within the AO.
- Provides publicly available information on threat capabilities and limitations.

TASK ORGANIZATION CONSIDERATIONS

2-75. When task-organizing the OSINT section to satisfy intelligence and information requirements, units must consider—

- Mission command.
- Acquisition.
- Collecting and processing.
- Production.
- Computer systems.

MISSION COMMAND

2-76. Dedicated mission command personnel are needed in order to provide management and oversight of OSINT exploitation to ensure continued synchronization with maneuver elements, tasks, and requests.

ACQUISITION

2-77. Due to the volumes of publicly available information, acquisition through established information collection activities and systems are necessary in order to ensure that open-source information is not lost or misplaced that could provide essential and necessary mission-related information. Publicly available information acquired from open sources should be reported in accordance with established unit SOPs.

COLLECTING AND PROCESSING

2-78. OSINT properly integrated into overall collection plans during operations are used to satisfy CCIRs. In order to access the full array of domestic and foreign publicly available information, the processing of materials oftentimes requires OSINT support to personnel operating in the areas of document exploitation (DOCEX).

Note. Personnel engaging in the collecting and processing of information involving these aspects will require an understanding of those items and materials that are commonplace and those that could possess intelligence value. They must further be versed in the additional regulations for Director, National Security Agency (DIRNSA) oversight. Unless foreign publicly available information and open sources are collected and subsequently processed into a suitable form, the information will lose intelligence value.

PRODUCTION

2-79. Production of actionable and timely publicly available information through open sources is vital in OSINT exploitation. Research methods, Internet techniques (basic and advanced), and other associated tools are utilized to retrieve, integrate, evaluate, analyze, and interpret information into OSINT. Research information and finalized metadata as products are stored in databases accessible to other intelligence and nonintelligence personnel that have vested OSINT exploitation requirements.

COMPUTER SYSTEMS

2-80. OSINT personnel conducting OSINT exploitation need to have software allocated to the appropriate task. The necessary unfettered exploitation suite includes such programs as Analyst Notebook, Portable Document Format (PDF) Maker, and Text Chart.

Chapter 3

Collecting OSINT

Due to the unclassified nature of publicly available information, those engaging in OSINT collection activities can begin researching background information on their assigned area of responsibility long before the issuance of an official military deployment order while generating intelligence knowledge. IPB, an integrating process for Army forces, is the mechanism identifying intelligence and information requirements that can be satisfied utilizing publicly available information and open sources.

COLLECTING PUBLICLY AVAILABLE INFORMATION

3-1. Publicly available information and open-source research, applied as an economy of force, is an effective means of assimilating authoritative and detailed information on the mission variables (METT-TC) and operational variables (political, military, economic, social, information, infrastructure, physical environment, time [PMESII-PT]). The compilation of unanswered intelligence and information requirements determined at the conclusion of the MDMP and IPB are exercised through the commander's input. Commander's input—

- Is expressed in the terms of describe, visualize, and direct.
- Is the cornerstone of guidance used by OSINT personnel.
- Validates intelligence and information requirements.

3-2. Commander's input is expressed as CCIRs and categorized as friendly force information requirements (FFIRs) and PIRs. Continuous research and processing methods, coupled with the commander's input and intelligence and information requirements, OSINT personnel collect publicly available information for exploitation. The *collect* step of the intelligence process involves collecting, processing, and reporting information in response to information collection tasks. Collected information is the foundation of intelligence databases, intelligence production, and situational awareness.

3-3. OSINT is integrated into planning through the continuous process of IPB. Personnel engaging in OSINT exploitation must initiate collection and requests for information to satisfy CCIRs to the level of detail required. Collecting open-source information comprises four steps, as shown in figure 3-1 on page 3-2:

- Identify information and intelligence requirements.
- Categorize intelligence requirements by type.
- Identify source to collect the information.
- Determine collection technique.

IDENTIFY INFORMATION AND INTELLIGENCE REQUIREMENTS

3-4. Intelligence and information gaps are identified during the IPB process. These gaps should be developed and framed around the mission and operational variables in order to ensure the commander receives the information needed to support all lines of operations or lines of effort. As information and intelligence are received, OSINT personnel update IPB products and inform the commander of any relevant changes. OSINT needs clearly stated information and intelligence requirements to effectively focus

acquisition and production and should be incorporated into collection plans in order to satisfy these requirements.

Note. OSINT cannot eliminate all the unknown aspects or uncertainties that concern commanders and staffs. The G-2/S-2 must be prepared to fill gaps with reasonable assumptions; once gaps are filled, the G-2/S-2 must begin developing databases at the unit level in order to have information readily available. This reduces the number of new requests for information from subordinate units or organizations.

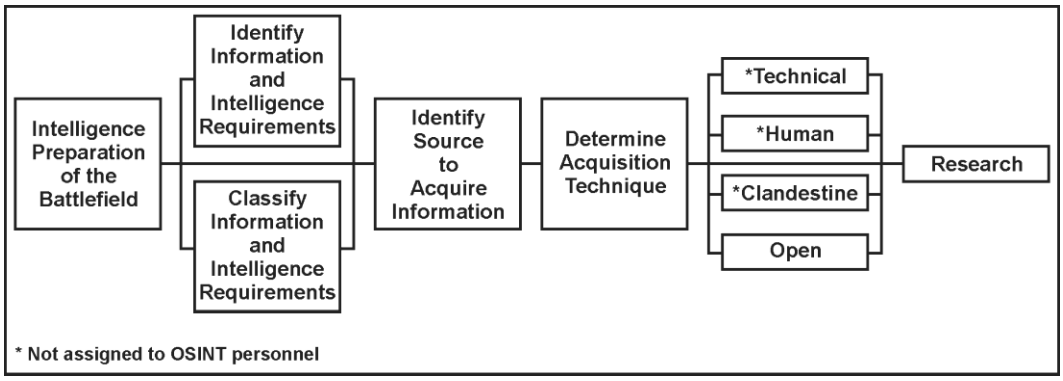

Figure 3-1. Process for collecting publicly available information

CATEGORIZE INTELLIGENCE REQUIREMENTS BY TYPE

3-5. Intelligence requirements that need to be satisfied can extend beyond the scope of OSINT, resulting in gaps. OSINT is subject to information and intelligence gaps that need to be satisfied using other appropriate methods to close those gaps.

3-6. IPB is used to classify intelligence and information requirements by type based on mission analysis and friendly COAs. OSINT personnel provide input during this step. Two important related terms that work in concert with OSINT are private information and publicly available information:

- **Private information** comprises data, facts, instructions, or other material intended for or restricted to a particular person, group, or organization. Intelligence requirements that require private information are not assigned to OSINT sections. There are two subcategories of private information:
  - ***Controlled unclassified information*** requires the application of controls and protective measures, for a variety of reasons (that is, *sensitive but unclassified* or *for official use only*).
  - ***Classified information*** requires protection against unauthorized disclosure and is marked to indicate its classified status when produced or disseminated.
- **Publicly available information** comprises data, facts, instructions, or other material published or broadcast for general public consumption; available on request to a member of the general public; lawfully seen or heard by any casual observer; or made available at a meeting open to the general public.

Note. The amount of classified information produced on any one topic can be limited and taken out of context if viewed from a solely classified perspective. OSINT validation is necessary when dealing with a large amount of classified information. OSINT validation is used when classified sources are unavailable or to confirm or support preexisting classified sources. This strengthens the credibility of OSINT products in support of all-source intelligence. OSINT validation provides the ability to cue other assets thus enhancing the accuracy and precision of gained intelligence.

IDENTIFY SOURCE TO COLLECT INFORMATION

3-7. Identifying the source is part of planning requirements and assessing collection plans. The two types of sources used to collect information are confidential sources and open sources:

- **Confidential sources** comprise any persons, groups, or systems that provide information with the expectation that the information, relationship, or both are protected against public disclosure. Information and intelligence requirements that require confidential sources are not assigned to OSINT sections.
- **Open sources** comprise any person or group that provides information without the expectation of copyright or privacy—the information, the relationship, or both is not protected against public disclosure. Open sources include but are not limited to—
  - ***Academia.*** Courseware, dissertations, lectures, presentations, research papers, and studies in both hardcopy and softcopy covering subjects and topics on economics, geography (physical, cultural, and political-military), international relations, regional security, and science and technology.
  - ***Government agencies and nongovernmental organizations.*** Databases, posted information, and printed reports on a wide variety of economic, environmental, geographic, humanitarian, security, and science and technology issues.
  - ***Commercial and public information services.*** Broadcasted, posted, and printed news on current international, regional, and local topics.
  - ***Libraries and research centers.*** Printed documents and digital databases on a range of topics.
  - ***Individuals and groups.*** Handwritten, painted, posted, printed, and broadcasted information on subjects and topics on art, graffiti, leaflets, posters, tattoos, and Web sites.
  - ***Gray literature.*** Materials and information that are found using advanced Internet search techniques on the Deep Web consisting of technical reports, scientific research papers, and white papers.

DETERMINE COLLECTION TECHNIQUE

3-8. Collection implies gathering, by a variety of means, raw data and information from which finalized intelligence is then created or synthesized, and disseminated. Collected information is analyzed and incorporated into all-source and other intelligence discipline products. These products are disseminated per unit SOPs, OPORDs, other established feedback mechanism, or intelligence architecture. These techniques confirm the presence of planned targets and provide a baseline of activity and information on sources within the AO for further development and future validation. When gathering information, the utilized technique includes specific information requests, objectives, priorities, timeframe of expected activity, latest (or earliest) time the information is of value (LTIOV), and reporting instructions.

3-9. Open-source information that satisfies a CCIR is disseminated as quickly as possible to the commander and other staff personnel per unit SOPs or OPORDs. OSINT can use unintrusive collection techniques to cue more technical collection assets. Collection techniques, depending on operation complexities, can enhance the chances of satisfying intelligence and information requirements.

3-10. Open-source acquisition of information and intelligence requirements are assigned to OSINT personnel. Open-source collection includes the acquisition of material in the public domain. The extent to which open-source collection yields valuable information varies greatly with the nature of the target and the subject involved. The information might be collected by individuals who buy books and journals, observe military parades, or record television and radio programs.

RESEARCH

3-11. After determining the collection technique, OSINT personnel conduct research to satisfy intelligence and information requirements.

3-12. Research—

- Leads to the population of information and intelligence databases. These databases enable OSINT personnel to accurately respond to changes within the AO by providing requested information to satisfy requirements.
- Is used to gather information that contributes to providing an understanding of a problem and organizing the results comprehensively.
- Is used to generate intelligence knowledge before and during deployments.

3-13. Two types of research methods that can be used are—

- **Field research.** Personnel from academic, governmental, intergovernmental, and nongovernmental organizations acquire data from primary sources, as well as retrieve data and information from secondary sources. Field research—
  - Consists of participant observation, data collection, and survey research.
  - Is typically conducted at the operational and strategic levels when time is not a factor in the development of information and intelligence of the operational variables (PMESII-PT) to provide commanders situational awareness.
- **Practical research.** Intelligence personnel retrieve existing data and information from secondary sources. Practical research—
  - Is typically conducted at the tactical level when time is a factor in the development of information and intelligence of the mission variables (METT-TC) in providing commanders situational awareness.
  - Is primarily used among intelligence personnel that engage in OSINT exploitation.

3-14. All research begins with the determination of a research question and the development of a research plan.

DETERMINE RESEARCH QUESTION

3-15. Research begins with the determination of a research question expressed in the form of CCIRs regarding a given topic. In OSINT exploitation, the research question can be based on the mission variables (METT-TC) and operational variables (PMESII-PT). The research question is refined through the development of information and intelligence requirements to be satisfied. Those requirements that are not satisfied are included in the planning requirements and assessing collection plan where more technical means of collection can be utilized.

DEVELOP RESEARCH PLAN

3-16. Different facets of a question may be expressed as information and intelligence requirements. These requirements form the basis for the research plan. A research plan can use both field research and practical research. The plan consists of—

- Identification of information sources (both primary and secondary).
- Description of how to access those sources.
- Format for compiling the data.
- Research methodology.
- Dissemination format.

IMPLEMENT RESEARCH PLAN

3-17. Utilizing open-source media—the means of sending, receiving, and recording information—components, and associated elements (see table 3-1), OSINT personnel implement a research plan. The primary media used to implement a research plan include—

- Public speaking forums.
- Public documents.
- Public broadcasts.
- Internet Web sites.

Note. The table does not illustrate an all-inclusive list of open-source media types but rather the categories of open-source media to consider when collecting open-source information.

Table 3-1. Open-source media, components, and elements

Media	*Components*	*Elements*	
Public Speaking	Speaker	• Sponsor • Relationship	• Message
	Format	• Conference • Debate • Demonstration • Speeches	• Lecture • Rally • Loud speakers • Talk shows
	Audience	• Location	• Composition
Public Documents	Graphic	• Drawing • Engraving • Painting • Graffiti	• Photograph • Print • Posters
	Recorded	• Compact data storage device • Digital video disk	• Hard disk • Tape
	Printed	• Book • Brochure • Newspapers • Magazines • Government releases • “Dumpster diving” • Annuals	• Periodical • Pamphlet • Report • Novelties • Non-government releases • Leaflets • Business cards
Public Broadcasts	Radio	• Low frequency AM radio • Medium frequency AM radio • Short wave radio	• VHF FM radio • Satellite radio • Standard wave radio
	Television	• Ku band satellite television • VHF and UHF terrestrial television • Advertisements • Motion pictures	
Internet Web Sites	Communications	• Chat • E-mail • News; newsgroup	• Web cam • Web cast • Web log
	Databases	• Commerce • Education	• Government • Military organizations
	Information (Web page content)	• Commerce • Education	• Government • Military organizations
	Services	• Dictionary • Directory • Downloads • Financial	• Geospatial • Search and URL lookup • Technical support • Translation

AM	amplitude modulation	URL	uniform resource locator
FM	frequency modulation	VHF	very high frequency
UHF	ultrahigh frequency		

Public Speaking Forums

3-18. OSINT personnel conduct research by attending public speaking forums such as conferences, lectures, public meetings, working groups, debates, and demonstrations. Attending these and similar events are opportunities to build relationships with nonmilitary professionals and organizations. Intelligence personnel require a thorough understanding of the local culture and laws to ensure any collection activities are unintrusive and do not violate local customs or laws, such as the Chatham House Rule. It is recommended to have the SJA's oversight during such collection missions to ensure compliance with AR 381-10, procedure 10. OSINT personnel require situational awareness and cultural understanding that is typically done by establishing both military and nonmilitary relationships with attendees, identifying any modifications of a speaker's message, and identifying personnel of interest attending the event.

3-19. OSINT personnel engaging in open-source exploitation, utilize public speaking forums typically in operational environments dominated by either stability operations or counterinsurgency operations where the level of violence is low.

Note. The Chatham House Rule states, "When a meeting, or part thereof, is held under the Chatham House Rule, participants are free to use the information received, but neither the identity nor the affiliation of the speakers, nor any other participants, may be revealed." Questioning the invocation of the Chatham House Rule should be inquired before the engagement begins. An invoked Chatham House Rule changes the characterization of the source from an open to a confidential source and may demand collection restrictions to ensure compliance with intelligence oversight limitations. (See appendix A.)

Public Documents

3-20. When acquiring public documents, OSINT personnel must be aware of the local environment and use a technique that is unintrusive and appropriate for the situation. These techniques include but are not limited to—

- Photographing and copying documents available in public forums such as town halls, libraries, and museums.
- Finding discarded documents in a public area such as streets, markets, and restrooms.
- Photographing documents in public areas such as banners, graffiti, and posters.
- Purchasing documents directly from street vendors, newspaper stands, book stores, and publishers.
- Purchasing documents through a third party such as a wholesale distributor or book club.
- Receiving documents upon request without charge from the author, conferences, trade fairs, direct mail advertising.

Public Broadcasts

3-21. Regional bureaus of the DNI OSC collect on regional and international broadcast networks in accordance with open-source information and intelligence requirements. Coverage of regional and international broadcasts enables OSINT personnel and organizations to use assets from already identified sources. The four techniques used to acquire information of public broadcasts are—

- **Spectrum search.** Searching the entire spectrum to detect, identify, and locate all emitters to confirm overall activity. This search provides an overview of the amount and types of activities and where they are located in the spectrum.
- **Band search.** Searching a particular segment of the spectrum to confirm overall activity. By limiting the size of the search band, the asset can improve the odds of acquiring a signal.
- **Frequency search.** Searching for radio or television frequencies.
- **Program search.** Searching for radio or television programs. Programs vary by type, content characteristics, and media format. Program surveillance verifies and expands upon initial results.

Note. For best results, OSINT personnel should use these techniques in combination rather than independently to generate intelligence knowledge. The selection of the techniques depends on the mission, the number of personnel, and capabilities.

3-22. For detailed information on collecting information from public broadcasts, see the DNI OSC.

Internet Web Sites

3-23. The four steps to acquire information on Internet Web sites are—

- Plan Internet search.
- Conduct Internet search.
- Refine Internet search.
- Record results.

3-24. For more detailed information on research using Internet Web sites, see appendix C.

Chapter 4

Producing OSINT

The Army operates in diverse environments around the world. This diversity requires proper use of publicly available information and open sources in the production of OSINT. Given the volume of existing publicly available information and the unpredictability of requests for information and intelligence requirements, OSINT personnel engaging in open-source exploitation must be fluidly aware of and flexible when producing OSINT. Effective production ensures that commanders and subordinates receive timely, relevant, and accurate intelligence. OSINT personnel produce OSINT by evaluating, analyzing, reporting, and disseminating intelligence as assessments, studies, and estimates.

CATEGORIES OF INTELLIGENCE PRODUCTS

4-1. After receiving a mission through the MDMP and commander's intent—expressed in terms of *describe*, *visualize*, and *direct*—intelligence and information requirements are identified. Personnel engaging in OSINT exploitation typically gather and receive information, perform research, and report and disseminate information in accordance with the categories of intelligence products. (See table 4-1.) OSINT products are categorized by intended use and purpose. Categories can overlap and some publicly available and open-source information can be used in more than one product. (For more detailed information on the categories of intelligence products, see FM 2-0.)

Table 4-1. Categories of intelligence products

Indications and Warning
Indications and warning are intelligence activities intended to detect and report time-sensitive intelligence information on foreign developments that could involve an threat to the United States, U.S. ally, or U.S. citizens abroad. It includes forewarning of hostile actions or intentions against the United States, its activities, overseas forces, or allied/coalition nations (JP 2-0).
Current Intelligence
Current intelligence supports ongoing operations; it involves the integration of time-sensitive, all-source intelligence and information into concise, accurate, and objective reporting on the area of operations (AO) and current threat situation. One of the most important forms of current intelligence is the threat situation portion of the common operational picture. The intelligence officer is responsible for producing current intelligence for the unit. In addition to the current situation, current intelligence should provide projections of the threat's anticipated actions and their implications on the friendly operation. (See JP 2-0.)
General Military Intelligence
General military intelligence is intelligence concerning (1) military capabilities of foreign countries or organizations or (2) topics affecting potential U.S. or multinational military operations relating to armed forces capabilities, including threat characteristics, organization, training, tactics, doctrine, strategy, and other factors bearing on military strength and effectiveness and area terrain intelligence… (excludes scientific and technical intelligence (JP 2-0). This broad category of intelligence is normally associated with long-term planning at the national level. ***Note.*** This definition was shortened for brevity. The complete definition is available in JP 2-0.

Table 4-1. Categories of intelligence products (continued)

Target Intelligence
Intelligence that portrays and locates the components of a target or target complex and indicates its vulnerability and relative importance (JP 3-60). Target intelligence is the analysis of threat units, dispositions, facilities, and systems to identify and nominate specific assets or vulnerabilities for attack, reattack, or exploitation. It consists of target development and combat assessment. Target development is the systematic evaluation and analysis of target systems, system components, and component elements to identify high-value targets for potential engagement through lethal or nonlethal means. Combat assessments provide a timely and accurate estimate of the effects of the application of military force (lethal or nonlethal) and mission command warfare on targets and target systems based on predetermined objectives.
Scientific and Technical Intelligence
Scientific and technical intelligence is the product resulting from the collection, evaluation, analysis, and interpretation of foreign scientific and technical information. Scientific and technical intelligence covers foreign developments in basic and applied research and in applied engineering techniques and scientific and technical characteristics, capabilities, and limitations of all foreign military systems, weapons, weapon systems, and materiel, the related research and development, and the production methods employed for their manufacture (JP 2-01).
Counterintelligence
Information gathered and activities conducted to identify, deceive, exploit, disrupt, or protect against espionage, other intelligence activities, sabotage, or assassinations conducted for or on behalf of foreign powers, organizations or persons or their agents, or international terrorist organizations or activities (EO 12333). Counterintelligence analyzes the threats posed by foreign intelligence and security services, and international terrorist organizations, and the intelligence activities of non-state actors such as organized crime, terrorist groups, and drug traffickers.
Estimative
Intelligence that identifies, describes, and forecasts adversary capabilities and the implications for planning and executing military operations (JP 2-0). Estimates provide forecasts on how a situation may develop and the implications of planning and executing military operations. Estimative intelligence goes beyond descriptions of threat capabilities or reporting of threat activity and tries to forecast the unknown based on an analysis of known facts using techniques such as pattern analysis, inference, and statistical probability.

EVALUATE INFORMATION

4-2. Open sources are overt and unclassified. Due to these aspects of publicly available information and open sources, deception, bias, and disinformation are of particular concern when evaluating sources of information during OSINT exploitation. Information is evaluated in terms of—

- Communications.
- Information reliability and credibility.

COMMUNICATIONS

4-3. A simple communications model is typically two-way and consists of six parts:

- Intended message.
- Speaker (sender).
- Speaker's encoded message.
- Listener (receiver).
- Listener's decoded message.
- Perceived message.

4-4. The speaker and listener each have different perspectives and aspects of communications (as shown in table 4-2 on page 4-4). There are great challenges facing communicators as the message becomes encoded by the speaker and decoded by the listener.

4-5. Communications during public speaking engagements are often difficult to evaluate given the myriad of elements that can prevent a successfully transmitted message. Given the multiple elements taken simultaneously, public speaking events are subjective and can be misunderstood.

4-6. The speaker has an intended message through a verbal, nonverbal, vocal, or visual media channel or combination thereof. Within communications, the areas typically involved in preventing the true intent of the message are the sending method, environment, and receiving method. Having an understanding of these areas generally yields a greater success rate between the speaker and listener.

4-7. Verbal communication begins with a speaker imparting or interchanging thoughts, opinions, or information. This communication can be either positive or negative. The typical speaker has a communication type:

- Passive.
- Aggressive.
- Passive-aggressive.
- Assertive.

4-8. Speakers communicate verbally and nonverbally based on their beliefs, emotions, or goals. These types of communication are indicated in table 4-2 on page 4-4. It is important to understand the differences in communication styles, how they are interpreted by an audience in order to effectively communicate the message intended and avoid misunderstandings. Evaluating information acquired through public speaking venues can be challenging based on these factors. Using the table to compare these types of communication can assist collection personnel in determining the influences surrounding communicators and predicting how the messages may be perceived. Table 4-2 illustrates and provides a guideline to assist in determining the type of displayed behavior, beliefs, emotions, and goals.

Note. Table 4-2 is not intended to stand alone but used in support of all-source intelligence. Publicly available information and open sources are used to develop personality and characteristic traits of an individual. These traits include previous speeches, lectures, sermons, or statements that are used to determine a baseline of anticipated behavior and responses. There are external influences that can positively or negatively affect an individual. These external influences include but are not limited to consequences of disputing a superior's opinion, the atmosphere or setting (such as academic, religious, or political), or an impromptu public interview using a question and answer format.

INFORMATION RELIABILITY AND CREDIBILITY

4-9. OSINT personnel evaluate information with respect to reliability and credibility. It is important to evaluate the reliability of open sources in order to distinguish objective, factual information; bias; or deception. The rating is based on the subjective judgment of the evaluator and the accuracy of previous information produced by the same source.

4-10. OSINT personnel must assess the reliability and the credibility of the information independently of each other to avoid bias. The three types of sources used to evaluate and analyze received information are—

- **Primary sources.** Have direct access to the information and conveys the information directly and completely.
- **Secondary sources.** Conveys information through intermediary sources using the vernacular and summarizes or paraphrases information.
- **Authoritative sources.** Accurately reports information from the leader, government, or ruling party.

Note. Secondary and authoritative sources, such as government press offices, commercial news organizations, political campaign staffs, research center publications, newspapers, periodicals, databases, and libraries, can intentionally or unintentionally add, delete, modify, or filter the information made available to the public.

Table 4-2. Comparison of communication types

	Passive	*Aggressive*	*Passive-Aggressive*	*Assertive*
Behavior	• Keeps quiet. • Does not say what is actually felt, needed, or wanted. • Frequently puts oneself down. • Apologizes when expressing oneself. • Denies feelings of disagreements or indifferences.	• Expresses feelings and wants as though any other view is unreasonable or stupid. • Dismisses, ignores, or insults the needs, wants, and opinions of others.	• Fails to meet the expectations of others through 'deniable' means (such as forgetting or delays). • Denies personal responsibility for actions.	• Expresses needs, wants, and feelings directly and honestly. • Does not assume correctness or everyone feels similar. • Allows others to hold other views without dismissal or insults.
Nonverbal Communication	• Minimizes oneself. • Looks down, hunches shoulders, avoids eye contact. • Speaks softly.	• Enlarges oneself and appears threatening. • Eye contact is fixed and penetrating. • Voice is loud, perhaps shouting.	• Typically mimics the passive style.	• Body is relaxed, and movements are casual. • Eye contact is frequent but not glaring.
Beliefs	• Others' needs are more important. • Others have more rights. • Others' contributions are more valuable.	• Personal needs are more important and more justified than others'. • Others have no personal rights. • Personal contributions are more valuable.	• Entitled to get own way, even after making commitments to others. • Not responsible for personal actions.	• Everyone's needs are equally important. • Everyone has equal rights to be expressive. • Everyone has valuable contributions. • Responsible for personal behavior.
Emotions	• Fears rejection. • Feels helpless, frustration, and anger. • Bears resentment toward others' mistreatment. • Has reduced self-respect.	• Angry or powerful at the time of victory. • Feels remorse, guilt, or self-hatred for hurting others.	• Fears assertiveness. • Resents the demands of others. • Fears of being confronted.	• Feels positive about oneself and the treatment of others. • High level of self-esteem.
Goals	• Avoids conflict. • Pleases others at any expense. • Gives others control.	• Wins at any expense to others. • Gets control over others.	• Gets personal way without having to take responsibility.	• Self-respect is kept by everyone. • Expresses oneself without having to win all the time. • No one controls anyone else.

4-11. Nonauthoritative sources lack reliability and trustworthiness and seldom stand apart from authoritative sources. The information provided by nonauthoritative sources generally does not support topics agreed upon as being true and reliable in academia. Nonauthoritative sources also make finding additional in-depth information difficult to locate.

4-12. Nonauthoritative sources are generally unavailable and inaccessible by the public. Nonauthoritative sources are uncorroborated by multiple public sources of information. Examples of nonauthoritative sources include but is not limited to—

- Unreviewed documents from self-published Web repositories such as blogs, Wikipedia, political sites, and commercial advertising.
- Material received via uncorroborated e-mail, hearsay, or statements solely in oral form.
- Informal personal communications such as letters to the editor and opinion essays.

4-13. When evaluating sources of information to determine reliability and credibility consider—

- **Identity.** *Who* produced the information (for example a student, teacher, political organization, or reporter)?
- **Authority.** *How* much does the source know about the information?
- **Motive.** *Why* was the information published?
- **Access.** Did the source have direct access to the event or information?
- **Timeliness.** *What* is the date of the information?
- **Internal and external consistency.** Does the information contradict governmental policies among local citizens?

PROCESS INFORMATION

4-14. *Process* is an information management activity: to raise the meaning of information from data to knowledge (FM 6-0). The function of processing, although not a component of the intelligence process, is a critical element in the analyzing and producing of OSINT. Publicly available information answers intelligence and information requirements. Based on the type of information received, it must be processed before being reported and disseminated as finalized OSINT. Intelligence personnel transform publicly available information and open sources into a form suitable for processing by—

- Digitizing.
- Transcribing and translating.

DIGITIZING

4-15. OSINT personnel create a digital record of documents by scanning or taking digital photographs. Pertinent information about the document must be annotated to ensure accountability and traceability. Digitization enables the dissemination of the document to external databases and organizations, as well as enables the use of machine translation tools to screen documents for keywords, names, and phrases.

TRANSCRIBING AND TRANSLATING

4-16. A *transcript* refers to a written verbatim, native language rendering of the spoken words in an audio or video recording. Both listening and writing proficiency in the source language are essential for an accurate transcript. The transcript includes descriptions of the activity, background, and conditions that the transcriber hears in the audio and observes in the video. The linguist uses online dictionaries, gazetteers, working aids, and software to improve the transcript. Once completed, the transcription is sent to a quality control linguist.

4-17. A *translation* is not verbatim but an approximation of the literal and implied meaning of the foreign language. The linguist must be able to read and comprehend the source language, write comprehensibly in English, and choose the equivalent expression in English that fully conveys and best matches the meaning intended in the source language.

4-18. During processing, a linguist creates either an extract, a summary, or a full translation of the original document or transcript into a standardized format established by unit SOPs. The linguist uses online dictionaries, gazetteers, working aids, and software to improve the translation. Once completed, the translation is sent to a quality control linguist.

4-19. Linguists perform quality control reviews of each transcription and translation to ensure both quality and consistency with established unit SOPs. A U.S. Government or military linguist should review all information that a non-U.S. Government linguist processes with exceptions involving long-term multinational partners of the United States and U.S. contractors with the requisite skills and the confidence of the command. Linguistic quality control is an important facet to process foreign publicly available information. Each transcription and translation undergoes two levels of review:

- **Quality control.** During quality control, a qualified linguist ensures that the transcription or translation is accurate, complete, free of bias, and in accordance with reporting and dissemination standards. The U.S. linguist returns the transcript or translation for correction, adds or corrects missed content, or corrects minor format errors. Upon completion of quality control, the transcription or translation is available for processing.
- **Quality assurance.** During quality assurance, a qualified U.S. linguist or OSINT analyst reviews the transcript or translation to ensure that it contains all required information and reads naturally in English. Once reviewed, the completed transcription or translation is saved to internal databases to be processed for reporting and dissemination.

ANALYSIS OF MEDIA SOURCES

4-20. Analysis of the media is the systematic comparison of the content, behavior, patterns, and trends of organic media organizations and sources of a country. Analysis of the media as an activity was developed and based on methods and experience gained during OSINT exploitation against authoritarian political systems during the World War II and Cold War eras where media was government-controlled. Publicly available information and open sources must be analyzed for proper inclusion in OSINT processing. OSINT personnel weigh media analysis against set criterion. These criterions assist OSINT personnel to discern facts, indicators, patterns, and trends in information and relationships. This involves inductive or deductive reasoning to understand the meaning of past events and predict future actions.

4-21. Comparison of trends in the content of individual media with shifts in official policy suggests that some media continues to mirror the dominant policy line. By establishing a track record for media that is vulnerable to external and internal pressure to follow the central policy line, OSINT personnel can identify potential policy shifts. Comparison of *what is said* and *what is not said* against the background of *what others are saying* and *what has been said before* is the core of media source analysis.

4-22. Media source analysis is also important in semi-controlled and independent media environments. In media environments where both official and nonofficial media are present, official media may be pressured to follow the central policy line. Analyzing media in these environments must encompass both the journalist and commentator level. It is important to establish the track record of such individuals to discover access to insider information from parts of the government or being used by officials to float policies.

Note. Differences in content between media outlets controlled by different official elites can reveal policy and leadership disputes. For example, a report on a speech by the President covered by government-controlled media may reveal differences from reports covering the same speech in either a semi-controlled or independent media environment.

4-23. The three aspects of media source analysis are—

- Media control.
- Media structure.
- Media content.

Media Control

4-24. Analyzing media environments in terms of media control requires awareness by intelligence personnel of how different elements of the media act, influence, and are of intelligence value. Careful examination of the differences in how media is handled in different types of environments can provide insight into domestic and foreign government strategies. Media environments are categorized as—

- **Government-controlled.**
  - Control over the media is centralized.
  - The dominant element of control is the government and higher tiers of political leadership.
  - Governments use censorship mechanisms to exercise control over media content prior to dissemination of information.
- **Semi-controlled.**
  - Control over the media is semi-centralized.
  - Governments exercise and promote self-censorship by pressuring media managers and journalists prior to dissemination of information.
- **Independent.**
  - Control over the media is decentralized.
  - Governments may regulate allocation of broadcast frequencies, morality in content, ownership in media markets, and occasionally apply political pressure against media or journalists.
  - Economic factors, norms of the journalist profession, the preferences of people who manage media, and the qualities of individual journalists who report or comment on the news all influence or control media content.

4-25. All media environments are controlled to some degree and therefore easier to perform media source analysis. The challenge for OSINT personnel is to determine the level, factors, and elements (see table 4-3) that elites, institutions, or individuals exercise control, how much power each possesses, and what areas are of interest to satisfy intelligence and information requirements.

Table 4-3. Level, factors, and elements of media control

Level	*Factor*	*Elements*
Political	The laws and norms governing operations of the media, officials, and the distribution of power	• Top leadership consensus • Top leaders individually • Institutions
Journalist	The degree of freedom afforded to the media by the political system that is subordinated from media executives, to media managers, and to individual journalists	• Board of directors of media companies • Individual directors • Influential shareholders • Managing editors • Department editors • Program producers • Anchors • Individual journalist
Individual	The laws and norms governing the appearance and behavior of individuals in the media	• Group of subjects or participants • Individual subject or participant

Media Structure

4-26. Media structure encompasses attributes of media material. There are structural elements that affect the meaning and significance of the content of the item and are often as important as the content itself. Analysis of these elements uncovers insights into the points of view of personnel in government-controlled, semi-controlled, and independent environments to establish the structure of media elements.

4-27. The media structural elements are—

- Selection, omission, and slant.
- Hierarchy of power.
- Format.
- Media type.
- Prominence.
- Dissemination.
- Timing.

Selection, Omission, and Slant

4-28. Selection of media items is a fundamental editorial decision at the core of news reporting. Selection includes media manager decisions about which stories are covered, which stories are not covered, and which slant (viewpoint), images, and information should be included, emphasized, deemphasized, or omitted in a news item.

Hierarchy of Power

4-29. All political systems involve a hierarchy of power (see table 4-4) that logically follows official statements issued by elements in corresponding hierarchy of authoritativeness. Authoritativeness is the likelihood that the views expressed in the statement represent the dominant viewpoint within the political system. The hierarchy is obvious at the political level—a statement by the prime minister trumps a statement by a minister. In other cases, the hierarchy may not be so obvious—a speech by the party chairman is more authoritative than the head of state.

Table 4-4. Hierarchy of media power

Information Type	*Purpose*	*Example*
Reports	Inform the viewer, listener, or reader	Authoritative or nonauthoritative based on track record
Commentary and editorials	State a position or opinion and persuade the viewer, listener, or reader	**Commentators** Authoritative: • Know pseudonym of top leader • Known advisor to Prime Minister • Associated with major party • Contributor to a major paper **Editors** Authoritative: • Ruling party's leaders or large donors • Large segment of political or financial elite • Large numbers of voters or small campaign contributors • Small segment of voters or population with special interests or radical views • Local officials and citizens
Official Statement	Declaration of policy or position by an officer or an executive body of the government or ruling party	Authoritative: • President • Secretary of State • State Department spokesperson

Format

4-30. Format consists of how media is produced and disseminated for public consumption. Format can be in the form of a live news report, a live interview, or a prerecorded report or interview that gives individuals more opportunity to influence the context delivered to consumers.

Media Type

4-31. Television is the medium with the largest potential audience in media environments and has a significant impact in shaping the impressions of the general viewing public. Television has replaced radio as the main source of news except in media environments where poverty prevents mass access to television. Fewer people may get information from newspapers and Internet news Web sites, but these people may be richer, better educated, and more influential than the general television audience. Specialized print publications and Internet Web sites reach a still smaller audience, but the audience will likely include officials and experts who that have influence on policy debates and outcomes.

Prominence

4-32. Questions to consider pertaining to prominence of media stories are—

- Does the story appear on the front page of newspapers or on the homepage of news Web sites?
- How much space is the story given?
- In what order does the story appear in the news broadcast?
- Is it featured in the opening previews of the newscast?
- How frequently is the story rebroadcast on subsequent newscasts or bulletins?
- How much airtime did it get?

Dissemination

4-33. Attention to patterns of dissemination of leader statements is important in government-controlled media environments. Leaders communicate publicly in a variety of ways such as formal policy statements, formal interviews, and impromptu remarks. By comparing the volume of media attention given to a statement, determination is made to whether the statement was intended to be taken as a pronouncement of established policy or merely as an ad hoc, uncoordinated expression prompted by narrow contextual or temporal conditions.

Timing

4-34. OSINT personnel have traditionally paid close attention to the timing of the appearance of information in the media as the information corresponds to the news cycle. A news cycle is the process and timing by which different types of media sources obtain information, incorporate or turn the information into a product, and make the product available to the public.

Media Content

4-35. Understanding the significance of media content can enhance the value of media source analysis. Media content encompasses the elements of—

- Manifest content.
- Latent content.

Manifest Content

4-36. Manifest content is the actual words, images, and sounds conveyed by open sources. One of the most important forms of media source analysis involves the careful comparison of the content of authoritative official statements to identify the policies or intentions represented. Governments, political entities, and actors use statements and information released to the media to strengthen, support, and promote policies.

4-37. Manifest content analysis of authoritative public statements is an effective tool to discern leadership intentions and attitudes. Manifest content, in order to be effective, consists of the following:

- **Esoteric communications** or "reading between the lines" are public statements whose surface meaning (manifest content) does not reveal the real purpose, meaning, or significance (latent content) of the author. Esoteric communication is particularly evident in political systems with strong taboos against public contention or in cases where sensitive issues are at stake. Esoteric communication is more formalized in some media environments than in others but is common in all political communications.
- **Multimedia content** analysis considers elements of content beyond the words used such as facial expressions, voice inflections of leaders giving a speeches or while being interviewed, or the reading of a script by a news broadcaster all provide indicators about the views of a subject or topic. These indicators assist to determine whether a statement was seriously considered, intended to be humorous, or simply impromptu.
- **Historical or past behavior** of open sources must be considered. Influences such as media outlet, journalist, newsmaker, or news broadcaster are factors beyond immediate control. Other issues such as time pressures, deadlines, or technical malfunctions, may also affect the content or context of public information. Analysts' judgments about source behavior must be made with careful consideration of previous behavior.

Latent Content

4-38. Latent content refers to the hidden meaning of a thought. Latent content can reveal patterns about the views and actions of the media controllers. These patterns and rules come from the unstated content that provides the underlying meaning of media content and behavior. When a pattern of content is changed, inference of a change in the viewpoint of the controller or a change in the balance of power among different controlling elements has occurred.

REPORT AND DISSEMINATE INFORMATION

4-39. Intelligence and information requirements satisfied through publicly available information and open sources should be immediately reported and disseminated in accordance with unit SOPs that are generally centered on intelligence requirements, information criticality, and information sensitivity.

Note. Staff personnel not directly assigned to the OSINT section also acquire information that is incorporated within the running estimate of each staff element. Close cooperation between these individuals fosters a supportive environment about *what* and *how* to report information of potential operational or intelligence value through the proper channels.

4-40. Finalized OSINT serves no purpose unless it is timely, accurate, and properly disseminated to commanders and customers in a useable form. Reporting and disseminating a finalized OSINT product that satisfies intelligence and information requirements include but are not limited to—

- Single discipline or multidiscipline estimates or assessments.
- Statements of facts.
- Evaluations of threat capabilities and limitations.
- The threat's likely COAs.

REPORTING GUIDELINES AND METHODS

4-41. Effective dissemination creates a mechanism of feedback in order to assess usefulness and predict or assess future intelligence and information requirements. The objective in reporting and disseminating intelligence and information is to provide relevancy to support conducting (planning, preparing, executing, and assessing) operations.

4-42. The basic guidelines in preparing products for reporting and disseminating information are—

- **Timely.** Information should be reported to affected units without delay for the sole purpose of ensuring the correct format.
- **Relevant.** Information must contribute to the answering of intelligence requirements. Relevant information reduces collection, organization, and transmission times.
- **Complete.** Prescribed formats and SOPs ensure completeness of transmitted information.

4-43. The three reporting methods used to convey intelligence and information are—

- **Written.** Methods include formats (spot reports), tactical reports (TACREPs), or information intelligence reports (IIRs).
- **Graphic.** Web-based report dissemination is an effective technique to ensure the widest awareness of written and graphical information across echelons. OSINT personnel can collaborate and provide statuses of intelligence requirements through Web sites. Information can also be uploaded to various databases to support future open-source missions and operations.
- **Verbal and voice.** The most common way to disseminate intelligence and information verbally is through a military briefing. Based on the criticality, sensitivity, and timeliness of the information, ad hoc and impromptu verbal communication methods are the most efficient to deliver information to commanders.

SECURITY DOMAINS

4-44. OSINT is disseminated via security domains. A security domain is an application or collection of applications that share the same authentication or authorization. A security domain determines the overall classification of an enclave of servers, computers, or networks. Networks are separated by classification in order to prevent the compromise of information. OSINT organizations can exchange publicly available information on unclassified and classified networks across echelons between Army and other armed forces as well as joint organizations and federal, state, and local government agencies.

4-45. The replication of Web sites and databases from unclassified networks to classified networks ensure publicly available information, open sources, and finalized OSINT products are reported and disseminated to intelligence and nonintelligence personnel to support unified land operations. The establishment of an effective OSINT architecture involves the proper utilization of the three primary security domains:

- Joint Worldwide Intelligence Communications System (JWICS).
- SIPRNET.
- NIPRNET.

Joint Worldwide Intelligence Communications System

4-46. JWICS is a system of interconnected computer networks used by various U.S. Government departments to transmit TS/SCI over the transmission control protocol/Internet protocol (TCP/IP) suite in a secure environment. JWICS supports the synchronization of OSINT exploitation, dissemination of OSINT and supporting metadata, and collaboration between deployed and supporting intelligence personnel.

SECRET Internet Protocol Router Network

4-47. SIPRNET is a system of interconnected computer networks used by various U.S. Government departments to transmit classified information over the TCP/IP in a secure environment. SIPRNET is the principal mission-command data network at the tactical level. The network allows access to OSINT services and products through various databases, as well as gives intelligence and nonintelligence personnel the ability to collaborate, view, submit, and track OSINT intelligence and information requirements.

Nonsecure Internet Protocol Router Network

4-48. NIPRNET is used by various U.S. Government departments to exchange information up to the sensitive but unclassified level. NIPRNET is configured to provide access to Internet-based capabilities across all DOD components. It is the domain most commonly used to conduct open-source research and produce OSINT.

REPORTING AND DISSEMINATION CONSIDERATIONS

4-49. When reporting and disseminating OSINT products, considerations include but are not limited to—

- **Classification.** When creating products from raw information, write-to-release at the lowest classification level to facilitate the widest distribution of the intelligence. Use tearline report formats to facilitate the separation of classified and unclassified information for users operating on communications networks of differing security levels. Organizations with original classification authority or personnel with derivative classification responsibilities must provide subordinate organizations and personnel with a security classification guide or guidance for information and intelligence derived from publicly available information and open sources in accordance with the policy and procedures in AR 380-5.
- **Feedback-mechanism development.** E-mail, postal addresses, rating systems, and survey forms are mechanisms that OSINT personnel can use in order to understand the information requirements for customers.
- **Intellectual property identification.** Identify intellectual property that an author or an organization has copyrighted, patented, or trademarked taken to preserve rights to the information. OSINT exploitation does not involve the selling, importing, or exporting of intellectual property. OSINT personnel engaging in exploitation should cite all sources used in reported and disseminated products. When uncertain, OSINT personnel should contact the supporting SJA office before reporting and disseminating a finalized OSINT product.
- **Use of existing dissemination methods, when and if possible.** Creating new dissemination methods can at times complicate existing dissemination methods.
- **Analytical pitfalls.** Analysts need to be cognizant that there are pitfalls when reporting and disseminating OSINT. The errors, referred to as fallacies (omission and assumption), are usually committed accidentally although sometimes they are deliberately used to persuade, convince, or deceive. Analysts must also be aware of hasty generalization, false cause, misuse of analogies and languages, biases (cultural, personal, organizational, cognitive), and hindsight. (For more information on analytical pitfalls, see TC 2-33.4.)

Appendix A

Legal Restrictions and Regulatory Limitations

Publicly available information and open sources cover a wide array of areas. Exploring, assessing, and collecting publicly available information and open sources has the potential to adversely affect organizations that execute OSINT missions. In some regards, OSINT missions could involve information either gathered against or delivered by U.S. persons. Given the scope of OSINT and its applicability within the intelligence community, having a firm awareness of intelligence oversight and its regulatory applications is necessary.

EXECUTIVE ORDER 12333

A-1. All OSINT exploitation conducted by intelligence and nonintelligence personnel must comply with the legal restrictions, policies, and guidelines outlined in EO 12333 and other associated regulations, instructions, or directives.

A-2. EO 12333 states the goal of the national intelligence effort is to provide the President and the National Security Council the necessary information on which to base decisions concerning the conduct and development of foreign defense, economic policy, and protection of U.S. national interests.

A-3. EO 12333 originated from operations that DOD intelligence units conducted against U.S. persons involved in the Civil Rights and anti-Vietnam War movements. DOD intelligence personnel used overt and covert means to collect information on the political positions of U.S. persons, retained the information in a nationwide database, and disseminated the information to law enforcement authorities.

A-4. The purpose of EO 12333 is to enhance human and technical collection techniques, the acquisition of foreign intelligence, and the countering of international terrorist activities conducted by foreign powers especially those undertaken abroad, and the acquisition of significant foreign intelligence, as well as the detection and countering of international terrorist activities and espionage conducted by foreign powers. Accurate and timely information about the capabilities, intentions, and activities of foreign powers, organizations, and subordinate agents is essential to informed national defense decisions. Collection of such information is a priority objective, pursued in a vigorous, innovative, and responsible manner that is consistent with the U.S. Constitution and applicable laws and principles.

INTERPRETATION AND IMPLEMENTATION

A-5. AR 381-10 interprets and implements EO 12333 and DOD 5240.1-R. AR 381-10 enables the intelligence community to perform authorized intelligence functions in a manner that protects the constitutional rights of U.S. persons. The regulation does not authorize intelligence activity. An Army intelligence unit or organization must have the mission to conduct any intelligence activity directed against U.S. persons. In accordance with the Posse Comitatus Act (Section 1385, Title 18, USC), the regulation does not apply to Army intelligence units or organizations when engaged in civil disturbance or law enforcement activities without prior approval by the Secretary of Defense.

ASSIGNED FUNCTIONS

A-6. Based on EO 12333, the assigned intelligence functions of the Army are to—

- Collect, produce, and disseminate military-related foreign intelligence as required for execution of responsibility of the Secretary of Defense.
- Conduct programs and missions necessary to fulfill departmental foreign intelligence requirements.
- Conduct activities in support of DOD components outside the United States in coordination with the Central Intelligence Agency (CIA) and within the United States in coordination with the Federal Bureau of investigation (FBI) pursuant to procedures agreed upon by the Secretary of Defense and the Attorney General.
- Protect the security of DOD installations to include its activities, property, information, and employed U.S. persons by appropriate means.
- Cooperate with appropriate law enforcement agencies to protect employed U.S. persons, information, property, and facilities of any agency within the intelligence community.
- Participate with law enforcement agencies to investigate or prevent clandestine intelligence activities by foreign powers or international terrorists.
- Provide specialized equipment, technical knowledge, or assistance to U.S. persons for use by any department or agency, or, when lives are endangered, to support local law enforcement agencies.

ARMY REGULATION 381-10

A-7. AR 381-10 enables any Army component to perform intelligence functions in a manner that protects the constitutional rights of U.S. persons. It also provides guidance on collection techniques used to obtain information for foreign intelligence and CI purposes. Intelligence activity is not authorized by this regulation.

COLLECTION OF U.S. PERSON INFORMATION

A-8. Collection, in this context, is the gathering or receiving information by intelligence personnel in the course of official duties with the intent to use or retain the information for intelligence purposes. Action must be taken to demonstrate intended use of the collected information such as producing an intelligence information report, incident report, or adding the information to an intelligence database.

A-9. There must be a link between the collection of the U.S. person information and the intelligence agency assigned mission. This link is particularly important when dealing with publicly available information, open-source information, and information data exploitation.

A-10. Army intelligence components may collect U.S. person information by lawful means but must be limited to the least intrusive means feasible and shall not violate the law (see DOD 5240.1-R). These least intrusive collection means must be attempted before utilizing more intrusive collection means such as—

- Acquisition from publicly available sources or with the consent of the U.S. person of interest.
- If proven unfeasible or inefficient, acquisition from cooperating sources.
- If proven unfeasible or inefficient, acquisition from other lawful means that do not require a warrant or Attorney General approval.
- If proven unfeasible or inefficient, an approval request for the use of techniques requiring a warrant or Attorney General approval.

A-11. Within the United States, Army intelligence components may collect foreign intelligence concerning U.S. persons by overt means when the following conditions are met:

- The foreign intelligence sought is significant and does not concern the domestic activity of the U.S. person.
- The foreign intelligence cannot be reasonably obtained by overt means.

- Collection has been coordinated with the FBI in order to prevent the disruption of current operations.

A-12. The following considerations apply to the collection of U.S. person information from the Internet:

- Army intelligence components must use government computers to access the Internet for official government business unless otherwise authorized.
- IP addresses, uniform resource locators (URLs), and e-mail addresses that are not associated with a U.S. person may be acquired, retained, and processed by Army intelligence components without making an effort to determine association with a U.S. person as long as the component does not engage in analysis focused upon specific addresses.

A-13. AR 381-10 does not authorize the collection of any information relating to a U.S. person solely because of personal lawful advocacy of measures opposed to government policy as embodied in the First Amendment to the U.S. Constitution. The First Amendment states that Congress shall make no law respecting an establishment of religion, or prohibiting the free exercise thereof; or abridging the freedom of speech, or of the press; or the right of the people peaceably to assemble, and to petition the government for a redress of grievances.

RETENTION OF U.S. PERSON INFORMATION

A-14. *Retention* refers only to maintaining information about U.S. persons that the Army intelligence component can retrieve by the person's name or other personal identifying data. AR 381-10, procedure 3, describes the kinds of U.S. person information that an Army intelligence component may knowingly retain without the individual's consent.

A-15. AR 381-10 authorizes the retention of U.S. person information under the following criteria:

- Information properly collected in accordance with AR 381-10, procedure 2.
- Army intelligence components acquired the information incidental to an otherwise authorized collection activity, and retained the information if it—
  - Could have been collected intentionally under the provisions of AR 381-10, procedure 2.
  - Is necessary to understand or assess foreign intelligence or CI.
  - Is foreign intelligence or CI collected from authorized electronic surveillance.

Note. *Electronic surveillance* refers to the acquisition of a nonpublic communication by electronic means without the consent of a person who is a party to an electronic communication or, in the case of a nonelectronic communication, without the consent of a person who is visibly present at the place of communication, but not including the use of radio direction-finding equipment solely to determine the location of a transmitter.

  - Is incidental to authorized collection and may indicate involvement in activities that may violate federal, state, local, or foreign law.
- Information relating to functions of other Army activities, DOD components, or non-DOD agencies. The information pertains solely to the functions and responsibilities of other activities, components or agencies, and is retained only as necessary to transmit the information to that agency. The transmittal is filed and destroyed under general correspondence records management. Army intelligence components will not retain the information in intelligence databases or repositories.

A-16. *Temporary retention* refers to the authorization for Army intelligence components to retain information up to 90 days, solely to determine if the information is, in fact, retainable under this regulation. The 90-day period starts upon receipt of the information.

A-17. *Other information* retained by Army intelligence components must be reported for oversight purposes and for necessary subsequent proceedings.

A-18. Access to U.S. person information retained in intelligence files, databases, and repositories is limited to those with a need to know the information. U.S. person information in intelligence files, databases, and

repositories is retained in accordance with disposition criteria in AR 25-400-2. Intelligence components will review intelligence files and databases annually. Intelligence components will specifically review U.S. person information to ensure its retention is still necessary to an assigned function. This ensures U.S. person information is not held beyond established disposition criteria, is retained for an authorized function, and was not retained in violation of this regulation. This does not apply to the Investigative Records Repository or other authorized long-term records holding areas.

DISSEMINATION OF U.S. PERSON INFORMATION

A-19. *Disseminate*, an information management activity, refers to communicating relevant information of any kind from one person or place to another in a usable form by any means to improve understanding or to initiate or govern action (FM 6-0). In other words, dissemination is the delivery of intelligence to users in a suitable form with application of the intelligence to appropriate missions, tasks, and functions. AR 381-10, procedure 4, governs the types of information regarding U.S. persons that Army intelligence organizations may disseminate without the person's consent outside the component which collected and retained the information.

QUESTIONABLE INTELLIGENCE ACTIVITY

A-20. Questionable intelligence activity occurs when intelligence operations potentially violate—

- Laws.
- EOs.
- Presidential directives.
- DOD or Army policies.

A-21. Intelligence personnel should report questionable intelligence activity through the chain of command, the inspector general, or directly to the Assistant to the Secretary of Defense for Intelligence Oversight in accordance with AR 381-10. The following are examples of questionable intelligence activity on improper collecting, retaining, or disseminating of U.S. person information:

- Collecting and gathering information about U.S. domestic groups not connected with a foreign power or international terrorism.
- Producing and disseminating intelligence threat assessments containing U.S. person information without a clear explanation of the intelligence purpose for which the information was collected.
- Collecting and gathering U.S. person information for force protection purposes without determining if the intelligence function is authorized.
- Collecting and gathering U.S. person information from open sources without a logical connection to the mission of the unit.

A-22. AR 381-10 directs intelligence organizations to refer questions concerning the interpretation of the instructions on collection, retention, and dissemination of U.S. person information to the local SJA's office.

ASSISTANT DEPUTY DIRECTOR OF NATIONAL INTELLIGENCE FOR OPEN SOURCE

A-23. The responsibilities of the ADDNI/OS include—

- Exercising the integration, evaluation, and oversight for the NOSE.
- Providing strategic oversight of and guides strategic involvement of OSINT.
- Chairing the National Open Source Committee (NOSC) and Open Source Board of Advisors.
- Overseeing the DNI OSC and the distributed NOSE.
- Ensuring the integration of the open-source collection management strategy.
- Developing oversight of the NOSE.
- Overseeing interagency sharing of open-source information.

INTELLIGENCE COMMUNITY

A-24. The responsibilities of the intelligence community include—

- Developing programmatic oversight and evaluation to be centralized under the ADDNI/OS.
- Supporting all intelligence disciplines.
- Establishing appropriate source and information validation and verification procedures of all open-source exploitation efforts.
- Developing metrics for overall open-source activities.
- Making all open-source information, products, and services available throughout the intelligence community.

NATIONAL OPEN-SOURCE COMMITTEE

A-25. The NOSC provides guidance to the NOSE. The responsibilities of the NOSC include—

- Developing appropriate operational standards for source or information verification, tradecraft, and training.
- Developing science and technology standards for metadata tagging and storage.

DIRECTOR OF NATIONAL INTELLIGENCE OPEN-SOURCE CENTER

A-26. The DNI OSC serves to advance the exploitation of open-source information through acquisition, procurement, analysis, and dissemination of products and services. The responsibilities of the DNI OSC include—

- Facilitating open-source exploitation for U.S. Government partners and customers.
- Securing appropriate licensing agreements for open-source customers.
- Developing open-source programs.
- Training personnel to properly exploit open-source information in accordance with security practices.

Appendix B

Cyberspace Internet Awareness

Intelligence and nonintelligence personnel conducting open-source research must be aware of the digital operational environment by minimizing and reducing cyber "footprints," practicing effective cyber OPSEC, utilizing safe online surfing techniques and habits, and understanding that embedded metadata can be contained in documents.

CYBERSPACE SITUATIONAL AWARENESS AND CYBER SECURITY

B-1. More than any other intelligence discipline, research involving publicly available information and open sources could unintentionally reveal CCIRs. Open-source research sometimes requires access to Internet Web sites that block browsing sessions originating from *.mil* or *.gov* sources. In the areas of computer information assurance and Internet security, internet awareness is needed in order to be effective, aggressive, and to successfully conduct open-source research and exploitation. Unjustified Internet Web-site restrictions have the potential to severely impede acquiring and the subsequent processing, reporting, and disseminating of publicly available information and open sources.

B-2. Awareness is the beginning of effective cyber security. Computers transmit machine specifications such as operating system, type of version of each enabled program, security levels, a history of Web sites visited, cookie information, user preferences, IP addresses, enabled languages, and referring URL when searching the Internet. Visitors are frequently redirected to alternate Web sites based on search criterion, location, language, and time the search is conducted.

B-3. The Internet is described as a "network of networks" due to the hundreds of thousands of interconnected networks consisting of millions of computers. Computers and users connected to the Internet are identified by a system-specific IP address that designates location. The IP address serves as the address where transferred information and datum is delivered. The concern therein rests in the understanding that while visiting nonstandard or questionable Internet Web sites in accordance with official duties, sensitive unit information could inadvertently be revealed.

B-4. *Cyberspace* is a global domain within the information environment consisting of the interdependent network of information technology infrastructures, including the Internet, telecommunications networks, computer systems, embedded processors, and controllers (JP 1-02). The Army operates in and through the cyberspace domain, using and managing the electromagnetic spectrum as a holistic and integrated part of unified land operations. Personnel engaging in OSINT exploitation need to understand the cyberspace environment in order to develop and identify outcomes-based, integration-focused, and resource-informed solutions for cyber situational awareness concerns.

B-5. *Cyber situational awareness* is the knowledge of friendly, neutral, and threat relevant information regarding activities in and through cyberspace and the electromagnetic spectrum (FM 1-02). Cyberspace and cyber security involve increasing cyber situational awareness by—

- Identifying threat operations to determine the effect on friendly operations and countermeasures.
- Determining how to use cyberspace to gain support from friendly and neutral entities.
- Determining how to gain, maintain, and exploit technical and operational advantages.

B-6. There are OPSEC and computer security risks to searching and interacting with Internet Web sites. Searching the Internet can compromise OPSEC by leaving "digital footprints" on visited Web sites. "Surfing" on Internet Web sites can compromise computer security by exposing the computer and network to malicious software (such as viruses, worms, and Trojan Horses) or unauthorized access. Intelligence personnel must be vigilant to potential threats, use only authorized hardware and software, and comply with established unit operations security measures.

B-7. URL information from the previous Web site visited is frequently an OPSEC issue and it identifies characteristics and interests of the user. While necessary for an effective research, the use of specific and focused search terms have potential OPSEC implications.

Cyber Security Example

If the user enters the search terms [bradley us army], the referring URL from the Google hit list would be: http://www.google.com/search?hl=en&q=bradley+us+army. This tells the visited site that the user is searching in English (hl=en) for information on Army General of the Army Omar N. Bradley or the U.S. Army's Bradley infantry fighting vehicle.

B-8. All actions on a Web site are logged and saved. The information is saved and linked to what is referred to as *cookie data*. User actions include but are not limited to—

- Words typed in search parameter fields.
- Drop-down menu choices.
- Check boxes.
- Web site movement patterns such as changing domain name or Web site address.

B-9. On many Web sites, information that the user provides or fills in becomes part of the Web site and is searchable. Key information to avoid sharing includes but is not limited to—

- Military plans.
- Operations.
- Exercises.
- Maps and charts.
- Locations.
- Schedules.
- Equipment vulnerabilities, capabilities, and shortfalls.
- Names and related numbers:
  - Telephone numbers.
  - Birth dates.
  - Identification numbers.

B-10. Traditional and irregular threats are disruptive in nature and use the cyberspace domain to conduct operations against the Army. These threats are innovative, networked, and technologically adept. These threats capitalize on emerging technologies to establish and maintain a cultural and social advantage leveraging areas, to include but not limited to mission command, recruiting, logistics, fund raising and laundering, IO, and propaganda.

B-11. When engaged in OSINT exploitation utilizing computer systems and Internet usage, cyberspace awareness assessments should be developed and cover areas including but not limited to network vulnerabilities, network threats (physical and virtual), and future risks.

B-12. For more detailed information about cyber security threats and tips see the U.S. Computer Security Readiness Team's Web.

Appendix C

Basic and Advanced Internet Search Techniques

The ability to search the Internet is an essential skill for open-source research and acquisition. The Internet, considered a reconnaissance and surveillance research tool, provides access to Web sites and databases that hold a wide range of information on current, planned, and potential areas of operation. The exponential growth in computer technology and the Internet has placed more publicly available information and processing power at the fingertips of Soldiers than ever before. A body of knowledge on culture, economics, geography, military affairs, and politics that was once inaccessible to some degree, now rest in the hands of high school and college students—future leaders of the Army.

THE WORLD WIDE WEB AND DEEP WEB

C-1. The Internet is a dynamic information environment consisting of stationary and moving virtual and target Web sites containing a mixture of old and new content. There are numerous virtual databases that grow at exponential rates. Keeping pace with technology is an enduring challenge for personnel that engage in OSINT exploitation utilizing the WWW and Deep Web.

WORLD WIDE WEB

C-2. The WWW is indexed by standard search engines. Standard search engines are typically incapable of accessing or retrieving the type of information necessary for conducting effective open-source research. The total amount of Internet information is estimated to be over 7,500 terabytes and continues to increase. Of this amount, customary search engines on the Internet are estimated to index only one-quarter of the information. Considered a very large amount of information, it only represents a fraction of the amount of open-source information available during research utilizing publicly available information. The other three-quarters (or roughly 5,625 terabytes) are contained on what is called the Deep Web.

THE DEEP WEB

C-3. The *Deep Web* refers to content that is not part of the traditional WWW. This content is estimated to be more than twice the content saved and accessible on the traditional WWW. The content and information contained on the Deep Web is designed around Web-based databases. Unlike the WWW, the Deep Web is not indexed. Nonstatic Web sites and databases located on the Deep Web cannot be accessed or indexed by traditional search engines. The Deep Web offers a tremendous amount of resources. Deep Web resources could fall into one or more of the following:

- **Dynamic content.** Web pages that are returned in response to a submitted query.
- **Unlinked content.** Web pages that are not linked to other Web pages that prevent standard Web crawling programs from accessing the content.
- **Private Web content.** Web pages without backlinks or inlinks.
- **Limited access content.** Web sites that limit access to information.
- **Nonhypertext markup language content.** Textual content encoded in multimedia files that are not handled by search engines.

SEARCH ENGINES

C-4. Search engines are the primary tools that personnel engaging in OSINT activities use when conducting research of publicly available information through open sources. OSINT personnel use search engines and search terms to locate text, images, and information on thousands of Web sites. Technically, search engines are actually searching through the index of Web sites. Commercial and government search engines vary in what parameters are searched, how searches are processed, and how search results are displayed. Most search engines use programs called *web crawlers* to build indexed databases. A web crawler searches Internet Web sites and files and saves the results in a database.

C-5. Most search engines use relevancy formulas to display results in a specific order with a brief description and hyperlink to the reference Internet file. Relevancy formulas evaluate how well the query matches the request. Relevancy formulas are significant to the user as search engines evolve and will not all yield similar results. The placement of keywords yield different results if rearranged due to more emphasis placed on one word over another. As search engines have evolved, some have become adept at finding specific types of information, such as statistical, financial, and news, more effectively. To overcome this specialization, software engineers have developed metasearch engines that allow the user to query more than one search engine at a time.

Search Engines

If a particular search engine cannot accommodate phrases in quotation marks or other types of Boolean functions, then the metasearch engine eliminates that function from the search. The resulting search then becomes too broad and less useful than a well-formatted search using a specialized search engine.

C-6. With an understanding of how search engines work, intelligence personnel—

- Conduct initial searches using unique keywords and combinations.
- Apply Boolean logic to improve search parameters.
- Conduct follow-on searches using natural language.

SEARCH BY KEYWORD

C-7. In keyword-based searches, OSINT personnel should consider what keywords are unique to the information being researched. Keywords should be balanced to yield relevant results without an over abundance of irrelevant information. Common words to be avoided include—

- A.
- An.
- And.
- The.

C-8. These words should be avoided in search terms unless part of the title of a book or article. Most search engines ignore common words. For example, if looking for information about Russian and Chinese tank sales to Iraq, do not use *tank* as the only keyword in the search. Instead, use additional defining words such as "Russian Chinese tank sales Iraq."

BOOLEAN LOGIC OPERATORS, CONNECTORS, AND DELIMITERS

C-9. When searching the Internet, the vast data available can be searched according to the rules of computer database searches. The logical relationship between search terms is referred to as *Boolean logic*. This method of searching provides options for constructing logical relationships among search terms using local operators, connectors, and delimiters.

C-10. Boolean logic operators, connectors, and delimiters assist intelligence personnel in establishing relationships between keywords to improve search activities.

Example of Using Boolean Logic Operators

Applying the following example, using the operators (see table C-1), the search engine searches for *Russian* and *tank* together when placed within parentheses—for example, *(Russian tank)*—and to exclude Chinese tank sales from the search result, use *(Russian tank) NOT (Chinese tank) sale Iraq* in the search. Intelligence personnel can also use a *NEAR* search when the relationship and the distance between the terms are well established. For example, if intelligence personnel are looking for incidents of tank sales in Baghdad and news articles normally place the name of the location within five words of *tank sales* in the title of the body of the article then use *tank sales NEAR/5* in the search.

Table C-1. Boolean logic operators, connectors, and delimiters

Function	*Boolean*	*Example*
Must be present *	AND	Chemical AND weapon chemical *weapon
Must not be present	NOT	Africa NOT Sudan
May be present	OR	Chemical OR biological
Complete phrase	* *	*Chinese tank sales to Iraq*
Nested	( )	(Shining Path)
Near**	NEAR	"White House" NEAR "airspace incursion"
Wildcards	Word* or *word	Gun* (gunpowder)

Note. Boolean searches may not work on all search engines. Using the "Advanced Search" option is available on many web browsers. Advanced search pages include fields to fill in such as "Find web pages that contain all these words;" "this exact wording or phrase;" or "Do not show pages including any of these words."

SEARCH IN NATURAL LANGUAGE

C-11. An alternative to using a keyword search is the *natural language* question format as most of the major search engines allow this capability. OSINT personnel obtain the best results when the question contains good keywords. One of the major downsides to this technique is the large number of results. If the needed information is not found in the results of the first few pages the question should be refined to initiate a new search using different parameters.

INTERNET WEB SITES

C-12. The four steps used to exploit publicly available information and open sources on Internet Web sites are—

- Plan Internet search.
- Conduct Internet search.
- Refine Internet search.
- Record results.

PLAN INTERNET SEARCH

C-13. OSINT personnel use an understanding of intelligence and information requirements to plan Internet searches. Intelligence and information requirements help to determine what information to search for, where to search, and provides the focus and initial keywords used in the search. After determining the focus and keywords, OSINT personnel use Internet browsers and search engines to connect to a previously identified Internet Web site.

Keyword Searches

If a unit is planning a humanitarian assistance operation in a particular country, intelligence requirements may be to locate refugee concentrations in that country. The task for an OSINT cell could include to locate—

- Humanitarian relief organizations operating food distribution centers.
- Population centers in the country.
- Concentrations of militia forces.
- Areas of militia operations within in the last 30 days.

Useful search terms would include—

- Refugee.
- Humanitarian relief.
- Militia.
- Water sources.
- Food distribution.

Locating possible indicators of where refugees may or may not concentrate include—

- Nongovernmental organization aid centers.
- Food.
- Water.
- Hostile militia forces.

Based on intelligence requirements, the search objective is to locate refugee concentrations based on the position of supplies and militia forces in the country.

CONDUCT INTERNET SEARCH

C-14. OSINT personnel conduct an initial search of likely sources using related terms or subject matter for the research question. The initial search is the first of potentially many subsequent searches for data and information that is retrieved and recorded in accordance with the research plan. Once retrieved, the information is integrated into the appropriate digital or analog database. OSINT personnel should avoid the temptation of using only one search engine as each has strengths and weaknesses. Organizational standards, research experience, and peer recommendations typically guide the selection of which search engine to use.

Note. If the information is not identified using multiple search engines within 30 minutes, it is possible that the information does not exist on the Internet, has not been indexed, or is not in a retrievable format.

REFINE INTERNET SEARCH

C-15. Typically, the first few pages of search results are the most relevant. Based on these pages, OSINT personnel exploit the initial search results for relevancy and accuracy for follow-on searches to determine if the results satisfied the intelligence or information requirement. Initial Internet searches can yield undesired results to satisfy intelligence and information requirements. OSINT personnel typically use measures to refine Internet results, including but not limited to—

- Reordering search terms.
- Adjusting upper or lower case.
- Searching within results.
- Searching in the cache and archive.
- Web site domains.
- Changing spelling and grammar.
- Using keyword variants.
- Searching by field.
- Truncating the URL.

Reorder Search Terms

C-16. Search engines may place a higher value on the first word or words in a multiple word or phrase search string. For example, changing the word order from *devices explosive* to *explosive devices* may yield different search results.

Change Spelling and Grammar

C-17. Search engines attempt to match the exact spelling of the words in the search string. There are search engines that recognize alternate spellings or prompt the user to correct common misspellings. For example, changing the spelling of a word from the American-English *center* to the British-English *centre* may yield different results. Boolean logic can also be used in order to circumvent potential spelling mistakes. Additionally, changing the spelling of a transliterated name generates different results that may be useful depending upon the objective of the search, such as the spelling variations of the name—

- *Al-Qaeda*.
- *al-Qaida*.
- *al-Qa'ida*.
- *el-Qaida.*
- *al Qaeda.*

Adjust Upper or Lower Case

C-18. Search engines may or may not support case sensitive searches. Some search engines attempt to match the word exactly as entered in the search. Most searches should be all lowercase letters. When looking for the name of a person, geographical location, title, or other normally capitalized word, use a case sensitive search engine. For example, changing the case of a word such as *java* to *JAVA* changes the results from coffee Web sites to software program Web sites.

Use Keyword Variants

C-19. OSINT personnel use terms that are culturally or geographically common. Using variants of a keyword such as changing *policeman* to *cop*, *bobby*, *gendarme*, *carabiniere*, *policía*, *politzei*, or other forms may improve search results.

Search Within Results

C-20. If the initial or follow-on search produces good but still unsatisfactory results, OSINT personnel can search within these results to produce a higher probability of finding the desired results. Most search engines display an option such as *search within these results* or *similar pages* to assist the user.

Search by Field

C-21. In a field search, OSINT personnel look for keywords within the URL as opposed to searching the Internet. This is typically done when the search engine returned a large number of results. While capabilities vary by search engine, some of the common field search operators are—

- **Anchor.** Searches for Web sites with a specified hyperlink.
- **Domain.** Searches for specific domains.
- **Like.** Searches for Web sites similar or related in some way to specified URLs.
- **Link.** Searches for specific hyperlinks embedded in a Web site.
- **Text.** Searches for specific text in the body of the Web site.
- **URL.** Searches for specific text in complete Web site addresses.

Search in Cache and Archive

C-22. Sometimes a search or an attempt to search with results returns a URL that matches exactly the search objective but when accessed the Web site is no longer active. If the search engine captures data as well as the URL locator, select the cached link to access the original data. OSINT personnel can also search an Internet archive Web site, such as www.archive.org, for the content. OSINT personnel need to have awareness that this information is historical and not subject to update by original creators.

Truncate the Uniform Resource Locator

C-23. Based on the topic of the information or intelligence requirement, OSINT personnel can manually search within the results by truncating the URL to a Web site. OSINT personnel work backwards from the original search result to the Web site containing the desired information or database by deleting the end segments of the URL at the forward slash. See manually truncating a URL example in table C-2.

C-24. There are also URL shortening assistance Web sites that redirect a user from a short URL (such as in the second part of table C-2) to a much longer URL serving as the actual address of the Web site. These are often used in social media services like Twitter due to the character restrictions placed on users.

Table C-2. Truncating and shortening uniform resource locators

Manually Truncating a Uniform Resource Locator (URL)	
Example URL to truncate	http://www.website.com/default.aspx?utm_source=twitter&utm_medium=social-media
Delete all but the main part of the Web site address	http://www.website.com/
Shortening URLs Using Shortening Assistance	
Example URL to paste into shortening assistance Web site	http://www.amazon.com/Kindle-Wireless-Reading-Display-Globally/dp/B003FSUDM4/ref=amb_link_353259562_2?pf_rd_m=ATVPDKIK X0DER&pf_rd_s=center-10&pf_rd_r=11EYKTN682A79T370AM3&pf_rd_t=201&pf_rd_p=1270985982&pf_rd_i=B002Y27P3M
The shortening Web site produces the example URL to use in social media settings or in e-mail	http://tinyurl.com/KindleWireless

Web Site Domains

C-25. Domain names on the Internet are identifying labels and are used in various networking contexts. They are used as simple identification labels to indicate ownership or control of a resource. With the millions of URLs on WWW, intelligence personnel are faced with a myriad of Web sites that may or may not produce or maintain the information presented in that domain. Certain domains, such as those listed in table C-3, are consistently reliable as being administered and authored by those types of organizations.

Note. OSINT personnel exploiting publicly available information and open sources must not take *.org*, *.info*, or *.net* extensions as necessarily produced by a bona fide organization for that domain.

Table C-3. Common Web site domains

Domain	*Description*
.aero	Reserved for members of the air transport industry
.biz	Restricted to businesses
.com	Unrestricted top-level domain intended for commercial content
.coop	Reserved for cooperative associations
.edu	Reserved for postsecondary institutions accredited by an agency on the U.S. Department of Education's list of Nationally Recognized Accrediting Agencies
.gov	Reserved exclusively for the U.S. Government
.info	Unrestricted top-level domain
.int	Used only for registering organizations established by international treaties between governments
.jobs	Reserved for human resource managers
.mil	Reserved exclusively for the U.S. military
.museum	Reserved for museums
.name	Reserved for individuals
.net	Reserved for networking technological individuals
.org	Intended for noncommercial use but open to all communities
.pro	Restricted to credentialed professionals and related entities

OPEN-SOURCE DATABASES, SOFTWARE, AND TOOLS

C-26. There are numerous COTS software applications, tools, and databases that are searchable using query words for research. Search engines used for research include but are not limited to—

- **Google Scholar.** Google Scholar provides a simple way to broadly search for scholarly literature. From one place, searches expand across many disciplines and sources that include articles, theses, books, and abstracts. Google Scholar helps locate relevant work across the world of scholarly research.
- **Spokeo.** Spokeo specializes in organizing people-related information (names, addresses, phone numbers) from phone books, social networks, marketing lists, business Web sites, and other public sources. Spokeo uses algorithms to piece together data into coherent profiles.
- **Blog Pulse.** BlogPulse is an automated trend discovery system for blogs by applying machine-learning and natural language processing techniques.
- **Pipl.** Pipl query engine helps locate Deep Web pages that cannot be found on regular or standard search engines. Pipl uses advanced language-analysis and ranking algorithms to retrieve the most relevant information about an individual.
- **Monitter.** Monitter is a browser-based Twitter search engine. Monitter displays three constantly updated keyword searches parallel to each other in your browser.
- **Maltego.** Maltego is a forensic application that offers data-mining and gathering of information into packaged representations. Maltego allows the identification of key relationships between information and identify previously unknown relationships.

GOOGLE TOOLS

C-27. Google tools assist in exploiting publicly available information and open sources through—

- Query words.
- Query types.
- Query modifiers.

QUERY WORDS

C-28. Google supports several advanced Boolean logic operators, which are query words that have special meaning to Google. Typically query types and query modifiers, when applied by operators, modify the parameters and results of search engines.

QUERY TYPES

C-29. Four categories covering most Web-search queries include—

- **Cache.** If other words are included in the query, Google highlights those words within the cached document. For example, [cache:www.google.com web] shows the cached content with the word "web" highlighted.
- **Link.** The query [link:] lists Web pages that have links to the specified Web page. For example, [link:www.google.com] lists Web pages that have links pointing to the Google homepage.
- **Related.** The query [related:] lists Web pages that are similar to a specified Web page. For example, [related:www.google.com] lists Web pages that are similar to the Google homepage.
- **Info.** The query [info:] presents some information that Google has about that Web page. For example, [info:www.google.com] shows information about the Google homepage.

QUERY MODIFIERS

C-30. Research using a specific search query can be modified using the following modifiers:

- **Site.** If [site:] is included in the query, the results are restricted to those Web sites in the given domain. For example, [help site:www.google.com] finds pages about *help* within www.google.com. [help site:com] finds pages about *help* within *.com* URLs.
- **Allintitle.** If a query starts with [allintitle:], the results are restricted to those Web sites with all of the query words in the title. For example, [allintitle: google search] returns only documents that have both *google* and *search* in the title.
- **Intitle.** If [intitle:] is included in the query, the results are restricted to documents containing that word in the title. For example, [intitle:google search] returns documents that have the word *google* in their title, and have the word *search* anywhere in the document (title or not). Putting [intitle:] in front of every word in the query is equivalent to putting [allintitle:] at the front of the query: [intitle:google intitle:search] is the same as [allintitle: google search].
- **Allinurl.** If a query starts with [allinurl:], the results are restricted to those Web sites with all of the query words in the URL. For example, [allinurl: google search] returns only documents that have both *google* and *search* in the URL.
- **Inurl.** If [inurl:] is included in the query, the results are restricted to those documents containing that word in the URL. For example, [inurl:google search] returns documents that have the word *google* in their URLs, and have the word *search* anywhere in the document (URL or not). Putting "inurl:" in front of every word in the query is equivalent to putting "allinurl:" at the front of the query: [inurl:google inurl:search] is the same as [allinurl: google search].

INTERNATIONAL INTERNET WEB SITES

The number of non-English-language users on the WWW and Deep Web are increasingly surpassing English users. This international reach results in the creation of foreign Web sites with specific country

codes. OSINT personnel must be aware of the origin of foreign Web sites and the potential vulnerabilities inherent in accessing these Web sites.

INTERNET SEARCH TECHNIQUE CONSIDERATIONS

C-31. When conducting Internet basic and advanced searches, technique areas that should be considered are—

- **COTS software.** When utilizing COTS tools and software, OSINT personnel must consider the tools and software utilized in accordance with unit SOPs, guidelines and policies.
- **Cataloging and archiving.** Due to the nature of Internet Web sites and the lack of control restrictions, Web sites can be removed from the WWW without prior notice.
- **Authorship.** Open-source products can oftentimes be authored through anonymity.
- **Identified Web sites and portals.** Familiarization of publicly available information generally results in standardized Web sites and portals used for research. Web sites and portals are subjective in nature due to the biases and perceptions of the Web site administrator or designer.
- **Off-line browsers.** Due to the volatile and unpredictability of Web sites, effective use of off-line browsers can enhance Internet research.

INTERNET AND OPERATIONS SECURITY VULNERABILITIES

C-32. The intent of OSINT is to exploit publicly available information and open sources without revealing user or organizational identities. Exploiting publicly available information and open sources is typically anonymous and conducted with a low risk of potential OPSEC compromise. There are inherent threats when conducting research on the WWW and Deep Web. Open-source research can compromise OPSEC and reveal user identification and the location of the computer systems through IP addresses. Any number of system disruption tools can render open-source collection activities ineffective. These include but are not limited to—

- **Viruses.** Computer codes that attach to computer programs. Once attached, viruses infect other computer systems through replication.
- **Trojan horses.** Computer programs that prevent user-activated commands.
- **Worms.** Self-contained computer programs that infect computers through replication. Worms create traffic on Web sites with the objective of decreasing visibility by conducting denial of service attacks.

Note. OSINT personnel should consult with organic unit's S-6/G-6 and information assurance personnel for current threats and guidelines to ensure that operating systems and browsers are using the most current security patches, antivirus, and antispyware protection software.

Appendix D

OSINT Contributions

The vignettes and discussions in this appendix illustrate how integrated OSINT supports or contributes to—

- Unified land operations and associated missions and tasks.
- Other intelligence disciplines.
- Other functions, such as site exploitation (SE) and source vetting.

The examples provided do not constitute a comprehensive list.

SUPPORT TO TARGETING, COUNTERINSURGENCY, AND IMPROVISED EXPLOSIVE DEVICE DEFEAT OPERATIONS

D-1. As a result of target development, OSINT contributes to the products such as target lists, target folders, target briefs, and exploitation requirements. The following vignette describes one situation where OSINT contributes to targeting. (For more information on targeting see FM 3-60.)

Example of OSINT Contributions to Targeting

The United States is going to war against Country X. The United States has an objective to limit the counterstrike capabilities of Country X. There is a significant military stockpile that Country X purposely collocated by a religious center. Should the United States destroy the stockpile knowing there is a great chance that the symbolic religious center will be destroyed as collateral damage?

OSINT can support this objective by providing information such as—

- What is the religious background of the population living near the religious center?
- Is the religious center culturally significant?
- Is it an historical landmark?
- What is the makeup of the congregation?
- What are the normal times that people congregate?
- What are the technical descriptions of the equipment in the stockpile?

D-2. In support of counterinsurgency operations, publicly available information is valuable for understanding the operational environment. It is often more useful than any other discipline for understanding public attitudes and public support during counterinsurgency operations. Publicly available information is also an important means of determining the effectiveness of inform and influence activities among the local populace. Monitoring public media benefits counterinsurgency operations. If possible, monitoring should occur at every echelon in support of PIRs. Each echelon should monitor the media that contain information relevant to operations at that echelon. For instance, at the corps level, major news networks should be monitored; in contrast, at the tactical level, local newspapers or radio stations may be more important. (For additional information on counterinsurgency operations, see FM 3-24.)

D-3. In support of improvised explosive device (IED) defeat operations, publicly available information can be used to—

- Collect and monitor IED-related information discussed during events that are open to the public or occur in public areas.
- Collect and monitor IED-related information that is located in any recorded public document (such as newspapers, magazines, leaflets, brochures, posters).
- Collect and monitor IED-related information that is broadcast for general public consumption to all receivers or terminals within a computer, radio, or television network.
- Monitor threat or IED-related Internet Web sites that may provide indications and warning of threat intentions, capabilities, activities, and responsible entities for a specific incident.

D-4. See FM 3-90.119 for more information on combined arms IED defeat operations.

SUPPORT TO OTHER INTELLIGENCE DISCIPLINES

D-5. Publicly available information and open sources developed as finalized OSINT can also support other intelligence disciplines.

HUMAN INTELLIGENCE

D-6. OSINT supports HUMINT collection operations by providing open-source materials to the appropriate J/G/S-2X and intelligence community agencies and liaison officers. These materials include but are not limited to—

- Maps.
- Charts.
- Phone directories.
- Business directories.
- Newspapers.
- Video and audio media (including tapes and CDs).

D-7. For further information on HUMINT collector operations see FM 2-22.3.

SIGNALS INTELLIGENCE AND GEOSPATIAL INTELLIGENCE

D-8. The following vignette describes a specific situation where OSINT directly contributes to signals intelligence (SIGINT) and geospatial intelligence (GEOINT).

Example of OSINT Contributions to SIGINT

The signals officer for Unit C is preparing an assessment based on an upcoming operation. The signals officer does not have access to classified systems. Unit C is preparing to conduct operations in an area where the media is state-controlled by a totalitarian government.

OSINT can support the signals officer by providing information such as—

- The identification of locally televised channels along with supporting components and systems.
- Web sites used to communicate to the local populace.

Example of OSINT Contributions to GEOINT

During mission planning, Engineer D is observing the potential effects of building a new rail system. The rail system will bisect an agricultural community located along a primary irrigation path. There is an increased potential that the rail system will disrupt and cause damage to the irrigation canals. There are time constraints preventing the request of satellite imagery in order to provide an overhead view of the area for assessment. If the rail system damages the irrigation canals, the results will more than likely destroy relationships established between unit leadership and tribal leaders.

OSINT can support imagery intelligence (IMINT) by providing information such as Google Earth and other COTS imagery to identify alternative waterways, future irrigation draining areas, and water paths in the event of flooding.

TECHNICAL INTELLIGENCE AND COUNTERINTELLIGENCE

D-9. Publicly available information supports technical intelligence (TECHINT) efforts in significant ways. Although adversaries and potential threats attempt to closely protect capabilities and vulnerabilities as well as intent, the inevitable results of technological advances, such as the Internet and Google Earth, provide exploitation opportunities into even the most secretive nations and organizations. (For further information on TECHINT, see TC 2-22.4.)

D-10. In support of CI, publicly available information can be used to obtain information that satisfies PIRs or other standing CI collection requirements. The collectors of Army OSINT are the military intelligence brigades. Military intelligence Soldiers receive OSINT training at their schools, as applicable. Upon arrival at permanent duty stations, unit training should include OSINT training relevant to duty assignments. (For more information on CI, see FM 2-22.2.)

Appendix E

OSINT Organizations

OSINT expands the entire breath of the intelligence community from the national level to the tactical level of operations. U.S. Government organizations, such as DOD, law enforcement agencies, and others that collect, acquire, exploit, analyze, disseminate, or utilize OSINT as a customer include—

- Defense Open Source Council (DOSC).
- INSCOM.
- DA IIS.
- DNI OSC.
- Open Source Academy.
- ASD.
- FBI.
- Federal Research Division (FRD), Library of Congress.

DEFENSE OPEN SOURCE COUNCIL

E-1. The DOSC is the primary governance mechanism for DOD OSINT. It serves as a forum for the coordination and facilitation of OSINT activities and programs for all Services and combatant commands. The DOSC advices and reports to the Under Secretary of Defense for Intelligence (USD[I]) on OSINT issues and recommends initiatives to improve the effectiveness and efficiency of OSINT programs, activities, and systems of the DOD. The responsibilities of the DOSC include but are not limited to—

- The coordination of activities and the resolution of OSINT programs and activities.
- The prioritization of OSINT requirements.

U.S. ARMY INTELLIGENCE AND SECURITY COMMAND

E-2. INSCOM conducts multidiscipline and all-source intelligence operations to include collection, analysis, production, and dissemination; knowledge management for the Army intelligence enterprise; as well as delivers specialized quick reaction capabilities, advanced skills training, and linguist support for deploying forces to enable battle command to support unified land operations.

E-3. INSCOM regionally supports each of the geographic combatant commands through subordinate regionally focused multifunctional military intelligence brigades. Each brigade manages intelligence requirements (to include OSINT) and provides support to Army tactical units deploying to or operating within a unified combatant command's area of responsibility or operational environment. Each multifunctional brigade has the capability to produce OSINT, generate requests to higher agencies, and answer collection requirements submitted by subordinate units at the tactical level through OSCAR-MS.

DEPARTMENT OF THE ARMY INTELLIGENCE INFORMATION SERVICE

E-4. DA IIS provides a broad spectrum of intelligence support functions to Army and intelligence community customers. DA IIS is the primary OSINT information and dissemination proponent for the Army. DA IIS is an element of Army G-2, Intelligence Information Management Directorate (DAMI-IM) and operational control is assigned to the INSCOM G-3. DA IIS is the primary intelligence information dissemination office for the Army. DA IIS provides a broad spectrum of intelligence support functions to Army and intelligence community customers, including Army Open-Source Collections Requirements Management.

E-5. The mission of the DA IIS is to coordinate, disseminate, and validate the strategic-level requests for open-source requirements Army-wide under the direction of the Army G-2. This is done by providing information sharing services across the intelligence community. The DA IIS is a voting member of the Office of the Director of National Intelligence (ODNI) NOSC Collection Requirements Management (CRM) subcommittee. DA IIS is the Army proponent office for OSINT. As such it addresses all aspects of OSINT policy, training, operational support, collection, production, analysis, and dissemination.

DIRECTOR OF NATIONAL INTELLIGENCE OPEN SOURCE CENTER

E-6. The DNI OSC supports the NOSE as directed by the ADDNI/OS. The OSC is an organization within the intelligence community, U.S. Government, private sector, and academia.

E-7. The operations of the OSC are driven by standing open-source requirements contained in the OSC's annually reviewed and approved information collection plans. The OSC maintains a worldwide network of multilingual regional experts that respond to intelligence and information requirements using publicly available information and open sources such as radio, television, newspapers, news agencies, databases, and the Internet. The OSC monitors open sources in more than 160 countries in over 80 languages and acquires open-source data worldwide for organizations across DOD, U.S. government agencies, and local law enforcement departments.

E-8. OSC services and tools facilitate OSINT efforts of agencies and offices throughout the U.S. Government and intelligence community by enabling the creation, management, and dissemination of unclassified products. The effectiveness and adaptability of OSC tools are—

- Highly developed for open-source exploitation and product creation.
- Designed to support and provide resources to a decentralized customer-base mainly through the Internet and readily available, purchased COTS content.
- Consistent with intelligence community security, technical, and metadata standards.

E-9. The OSC analyzes the content and behavior of media and Internet Web sites of nations and other international actors of significant policy interest to the U.S. Government.

OPEN SOURCE ACADEMY

E-10. The Open Source Academy is a leading provider of open-source tradecraft training. As intelligence consumers place a greater value on OSINT, open-source specialists throughout the U.S. Government are turning to Open Source Academy courses (see table E-1) to build open-source skills and to stay abreast of evolving OSINT technologies. The Open Source Academy is building relationships with community leaders across the intelligence community to develop a comprehensive approach to instilling open-source tradecraft skills. The academy hosts participants expanding across DOD, federal agencies, as well as local law enforcement departments.

Table E-1. Open Source Academy curriculum

• Introduction to the Field • Library Resources and Research Techniques • Media Analysis	• Visual Persuasion Methodology Advanced Googling • Audience Resonance Methodology

• Newcomer's Basic Desktop • Open-source Research and Analysis • Orientation to the Open Source Center • OS 101: Open-source Fundamentals • OS 201: Open-source 201 • Open-source Intelligence (OSINT) and the Other Intelligences • Overview of the Open Source Center Collection Requirements Process • Security and Privacy Issues for Internet Users • Smart Research—Partnering with the Library • Temporary Duty Workshop • Tools and Data Sources	• Classification Workshop • Community Digital Audio Video Enterprise (DAVE) System • Creating Multi-media Products • DAVE Executive Overview • Disseminations • Essentials of Open-source Analysis • Field Management • Fundamentals of Open Source Center Textual Production and Operations (PROPS) • Geospatial Analysis: An Introduction • Hidden Universes of Information on the Internet • High-end Workstation Block II 101 • High-end Workstation Block II 201

U.S. ARMY ASIAN STUDIES DETACHMENT

E-11. The ASD is the oldest, largest, and one of the most well-established OSINT activities in DOD that demonstrates the characteristics of sustained OSINT exploitation. The ASD collects, analyzes, exploits, processes, and reports short-to-mid-term analyses of publicly available information on military capabilities, force protection threats, and other operational-level intelligence information on countries, forces, and nonstate actors of interest in the USPACOM area of responsibility. Such requirements include the capabilities, disposition, and readiness of military forces in China, North Korea, and the Russian Far East, as well as defense-related topics throughout South and Southeast Asia. The ASD serves as a model for combatant command-level OSINT exploitation. The ASD workforce consists of Department of the Army Civilians and Army Reserve and National Guard Soldiers who serve as mission managers and editorial staff and Government of Japan-funded foreign nationals who perform all of the collection, analysis, translation, reporting, library, and graphics support functions.

E-12. The mission of the ASD is to collect, analyze, exploit, and report foreign OSINT in response to USPACOM and U.S. Army Pacific taskings and other national-level intelligence requirements. ASD's OSINT collectors, analysts, and reporters accomplish their wide-scope mission through the exploitation of print and Internet media materials.

E-13. ASD personnel extract and compile information into analytical products answering specific taskings received via the OSCAR-MS. The ASD synthesizes and cites open-source references in open-source intelligence report format similar to research papers or essays. ASD's current operations section provides a suite of daily media summary products containing press articles responding to more immediate and time-sensitive requirements for foreign media reflections of U.S. activities and other topics of interest. The services and tools that the ASD provide include but are not limited to—

- OSINT products responding to OSCAR-MS requirements.
- Analytical open-source intelligence reports.
- Daily force protection/situational awareness reports (FPSARs).
- Daily area surrounding Japan open-source intelligence reports (ASJORs).
- Daily situational reports (SITREPs).
- Weekly China and Taiwan Military photos reports.
- Ad hoc reporting as requested by customer in OSCAR-MS.
- OSINT product distribution on NIPRNET, SIPRNET, and JWICS.
- Map collection.
- Media summary reports.

FEDERAL BUREAU OF INVESTIGATION

E-14. The FBI is an agency of the Department of Justice that serves as both a federal criminal investigative body and an internal intelligence agency. The FBI has investigative jurisdiction over violations of more than 200 categories of federal crime.

E-15. The main missions of the FBI are to protect and defend the United States against terrorist and foreign intelligence threats and to uphold and enforce criminal laws. This is done by focusing on specific categories that include but are not limited to—

- Bank robbery.
- Robbery and extortion affecting interstate commerce.
- Drugs.
- Conspiracy.
- Sexual exploitation of minors.
- Mail fraud.
- Bank fraud.
- Fraud by wire, radio, or television.
- Illegal gambling businesses.

E-16. The FBI uses publicly available information through open sources in the areas of counterterrorism, CI, cybercrime, information technology, and forensics. Within the mission scope of the FBI, the services and tools provided include but are not limited to—

- Law enforcement bulletins.
- Crime mapping.
- Statistics (cybercrime, white-collar crime, and violent crime).

FEDERAL RESEARCH DIVISION, LIBRARY OF CONGRESS

E-17. The FRD was organized during World War II to collect and conduct research on captured aeronautical and technical reports on German and Japanese forces. These collections provided insight to future U.S. defensive posture developments and subsequently assisted in the intelligence effort leading to the defeat of the Axis powers.

E-18. The mission of the FRD is to provide directed research and analysis on domestic and international subjects to agencies of the U.S. Government, the District of Columbia, and authorized federal contractors. The FRD conducts open-source research for the U.S. Library of Congress. The services and tools that the FRD provide include but are not limited to—

- Primary research material, including document delivery.
- Foreign language abstracting and translation.
- Annotated bibliographies.
- Organizational and legislative histories.
- Studies and reports.
- Books.
- Military legal resources.
- Country studies.
- Country profiles.
- Terrorism and criminal studies and assessments.

Appendix F

Open-Source Resources

Intelligence personnel have access to vast amounts of information during research. Understanding and awareness of where to begin to look for specific information can be the largest obstacle analysts encounter. The tables in this appendix list some starting reference points for obtaining information that can be developed and produced into finalized OSINT. Table F-1 lists open-source training and resources that are specifically military.

Table F-1. Military open-source training and resources

Intelligence Knowledge Network (IKN):	
IKN is a knowledge management tool that enables intelligence Soldiers worldwide to communicate, collaborate, and investigate. IKN— • Hosts discussion forums. • Serves as a single point of entry to get to U.S. Army Intelligence Center of Excellence (USAICoE) and other intelligence community Web sites. • Hosts a variety of public and private Web applications that support the intelligence community.	
University of Military Intelligence (UMI):	
UMI is the distance learning arm of the military intelligence schoolhouse. From the UMI Web site, military intelligence professionals can access— • Self-paced and reachback training. • The Cultural, Foreign Language Integration Center. • Military intelligence training resources.	
Army Knowledge Online (AKO) Intelligence:	
AKO Intelligence features— • The Intelligence Collaboration Center. • Knowledge Center (documents, FMs, TCs, ATTPs, and others). • Training, agencies, policy, doctrine, and links to other intelligence-related Web sites.	
AKO Open-Source Program:	
AKO Army Open-Source Program features Open-Source— • Events. • Discussion forums. • Links of interest.	• Intelligence products. • Handbooks.
Military Intelligence Library:	***Available via the IKN and Warfighter Forum homepage***
Military Intelligence Library Reference Center includes many databases and resources, such as— • Journals and magazines. • Forms and publications. • Resource guide.	• Historical documents. • Cultural field readings. • Military Intelligence Foreign Language Training Center (MIFLTC).

Table F-1. Military open-source training and resources (continued)

DA IIS Country Research Portal: ***Available via the DA IIS portal from the AKO homepage***
The Department of the Army Intelligence Information Service (DA IIS) Country Research portal has road-mapped and data-mined networks resulting in a one-stop-shop for intelligence information. Some of the links on this Web site include— • Open-source documents such as Early Bird, Terrorism Daily Update, Baghdad Mosquito, Basra Bugle, and others. • Intelligence community. • Combatant commands. • Analyst references. • Foundry program. ***Note.*** Data is accessible through multiple networks to ensure that intelligence consumers have all required information necessary for mission success.
Intelink-U:
Intelink-U is the designated network of the Department of National Intelligence (DNI) for intelligence collaboration. The Intelink-U is— • Managed by the Intelink Management Office. • A joint-use, remotely accessed, and operationally-implemented information service that is used to access and process unclassified, publicly accessible information only. • Provides a protected environment to exchange authorized unclassified, unclassified for official use only, and sensitive but unclassified information among personnel of the DOD. ***Note.*** Access to Intelink-U services is implemented through multiple virtual private networks.

SECTION II – TERMS

esoteric communications

Public statements whose surface meaning (manifest content) does not reveal the real purpose, meaning, or significance (latent content) of the author.

media source analysis

The systematic comparison of the content, behavior, patterns, and trends of organic media organizations and sources of a country.

open source

Any person or group that provides information without the expectation of privacy—the information, the relationship, or both is not protected against public disclosure.

open-source intelligence

The discipline that pertains to intelligence produced from publicly available information that is collected, exploited, and disseminated in a timely manner to an appropriate audience for the purpose of addressing a specific intelligence requirement. (FM 2-0)

private information

Data, facts, instructions, or other material intended for or restricted to a particular person, group, or organization.

publicly available information

Data, facts, instructions, or other material published or broadcast for general public consumption; available on request to a member of the general public; lawfully seen or heard by any casual observer; or made available at a meeting open to the general public.

PREFACE

This publication provides preliminary joint and coalition training information on the subject of Open Source Intelligence (OSINT). It discusses the fundamentals of OSINT support to both the all-source intelligence process, and to the unclassified intelligence requirements of operators, logisticians, and civilian organizations participating in joint and coalition operations. The focus is on relevant information that can be obtained legally and ethically from the public and private sector, and that is not classified in its origin or processing. The information may become classified in relation to the commander's intent or its association with classified information when it is rightly blended into all-source intelligence reports.

This publication has been prepared under my direction as the Supreme Allied Commander, Atlantic, in collaboration with staff from the Supreme Allied Commander, Europe (SACEUR). This publication has benefited greatly from the continued collaboration between my staff and the staff of Open Source Solutions Inc. With the publication of this document and its companions, the *Intelligence Exploitation of the Internet* and the *NATO OSINT Reader*, commanders and their staffs will have basic guidance for the development of OSINT.

The increasingly robust array of open sources available to all staffs enable commanders at all levels to attempt to satisfy their information requirements themselves rather than immediately directing Requests for Information (RFIs) elsewhere. This manual outlines a systematic approach to OSINT exploitation.

This information is relevant to all NATO commands, task forces, member nations, civil-military committees and working groups, and such other organizations that may be planning or engaged in combined joint operations.

W. F. KERNAN
General, U.S. Army

EXECUTIVE SUMMARY

COMMANDER'S OVERVIEW

Open Source Intelligence (OSINT) in Joint and Coalition Operations

Open Source Intelligence, or OSINT, is unclassified information that has been deliberately discovered, discriminated, distilled and disseminated to a select audience in order to address a specific question. It provides a very robust foundation for other intelligence disciplines. When applied in a systematic fashion, OSINT products can reduce the demands on classified intelligence collection resources by limiting requests for information only to those questions that cannot be answered by open sources.

Open information sources are not the exclusive domain of intelligence staffs. Intelligence should never seek to limit access to open sources. Rather, intelligence should facilitate the use of open sources by all staff elements that require access to relevant, reliable information. Intelligence staffs should concentrate on the application of proven intelligence processes to the exploitation of open sources to improve its all-source intelligence products. Familiarity with available open sources will place intelligence staffs in the position of guiding and advising other staff elements in their own exploitation of open sources.

Open Source Intelligence and Joint or Coalition Operations

OSINT is a vital component of NATO's future vision. Through its concentration upon unclassified open sources of information, OSINT provides the means with which to develop valid and reliable intelligence products that can be shared with non-NATO elements of international operations. Experience in the Balkans, and the increasing importance of the Partnership for Peace and Mediterranean Dialogue members in security dialogue, illustrates the need to develop information sources that enable broader engagement with these vital partners.

Private Sector Information Offerings

The Internet is now the default C4I architecture for virtually the entire world. The principle exceptions are most militaries and intelligence organizations. The Internet facilitates commerce, provides entertainment and supports ever increasing amounts of human interaction. To exclude the information flow carried by the Internet is to exclude the greatest emerging data source available. While the Internet is a source of much knowledge, all information gleaned from it must be assessed for its source, bias and reliability.

As a source of reliable information, the Internet must be approached with great caution. As a means with which to gain access to quality commercial sources of validated information, the Internet is unbeatable.

A vision of open source exploitation must not be limited exclusively to electronic sources. Traditional print, hardcopy images and other analog sources continue to provide a wealth of data of continuing relevance to NATO intelligence.

The Open Source Intelligence Cycle

As the range of NATO information needs varies depending upon mission requirements, it is virtually impossible to maintain a viable collection of open source materials that address all information needs instantly. The focus should be on the collection of sources, not information. With knowledge of relevant and reliable sources of open source information, an intelligence staff can quickly devote collection energy and analytical expertise to develop tailored OSINT products to the mission need.

OSINT and the Emerging Future Intelligence Architecture of NATO

OSINT is an essential building block for all intelligence disciplines. Open sources have always played a role in classified intelligence production. In the NATO context, a robust OSINT capability greatly increases the range of information sources available to intelligence staffs to address intelligence needs.

Nations are capable of tasking classified intelligence sources to address intelligence gaps. Lacking organic intelligence collection assets, NATO intelligence staffs are unable to task classified collection. Rather than immediately directed a Request For Information (RFI) to a national intelligence centre, a robust OSINT capability enables intelligence staffs to address many intelligence needs with internal resources.

While unable to replace classified intelligence production, OSINT is able to compliment an all-source intelligence production process with essential support including tip-offs, context, validation and cover for information sanitation.

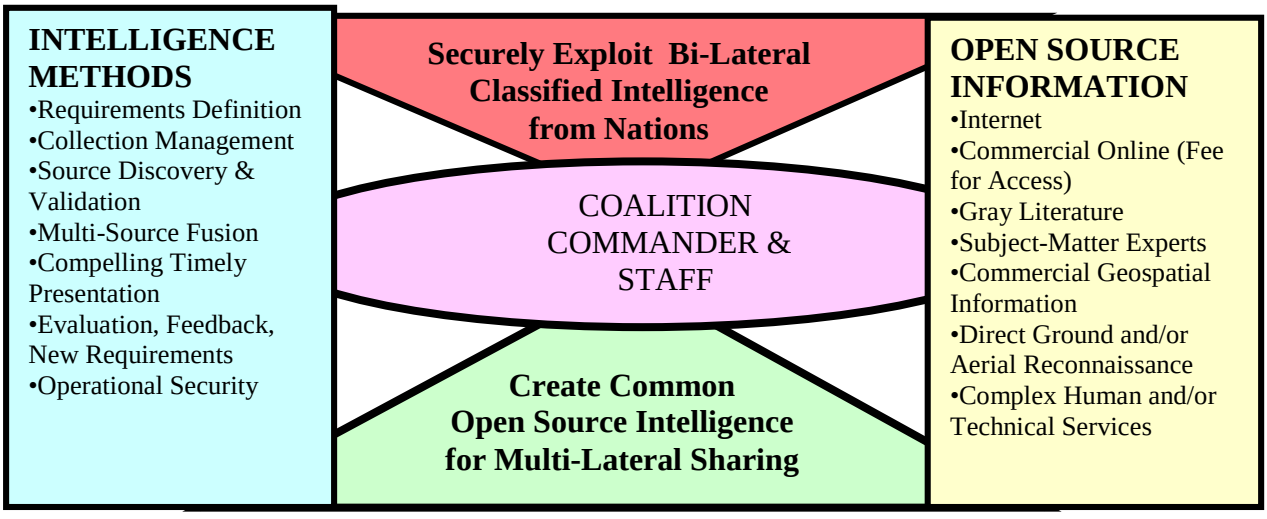
CHAPTER I
OPEN SOURCE INTELLIGENCE AND JOINT OR COALITION OPERATIONS

"OSINT is not a substitute for satellites, spies, or existing organic military and civilian intelligence capabilities. It is, however, a foundation—a very strong foundation—for planning and executing coalition operations across the spectrum from humanitarian assistance to total war. OSINT provides strategic historical and cultural insights; it provides operationally helpful information about infrastructure and current conditions; and it provides tactically vital commercial geospatial information that is not available from national capabilities. In coalition operations, OSINT is both the foundation for civil-military cooperation, and the framework for classified bilateral intelligence-sharing."

Introduction

OSINT is distinct from academic, business or journalistic research in that it represents the application of the proven process of national intelligence to a global diversity of sources, with the intent of producing *tailored* intelligence for the commander. OSINT is also unique, within a coalition operations context, in that it simultaneously provides a multi-lateral foundation for establishing a common view of the shared Area of Operations (AOO), while also providing a context within which a wide-variety of bi-lateral classified intelligence sharing arrangements can be exploited. Figure 1 illustrates these relationships.

Figure 1 - Relationship between Open Source and Classified Information Operations



OSINT is valuable to NATO member nations and to individual Partner nations in that it can be used to provide a common understanding of the AOO across all elements of its military forces and its civilian and non-governmental organization (NGO) counterparts. Elements of the forces not authorized access to the full range of classified information, often including such vital components, as military police, logistics elements, engineers, and the public affairs staff, can be made more effective through the utilization of tailored OSINT. At the same time, external parties with whom coordination is critical, but who are also not authorized access to classified information, can receive tailored OSINT that is helpful to a shared understanding of the AOO and the challenges facing the coalition and all its elements. Figure 2 illustrates this idea.

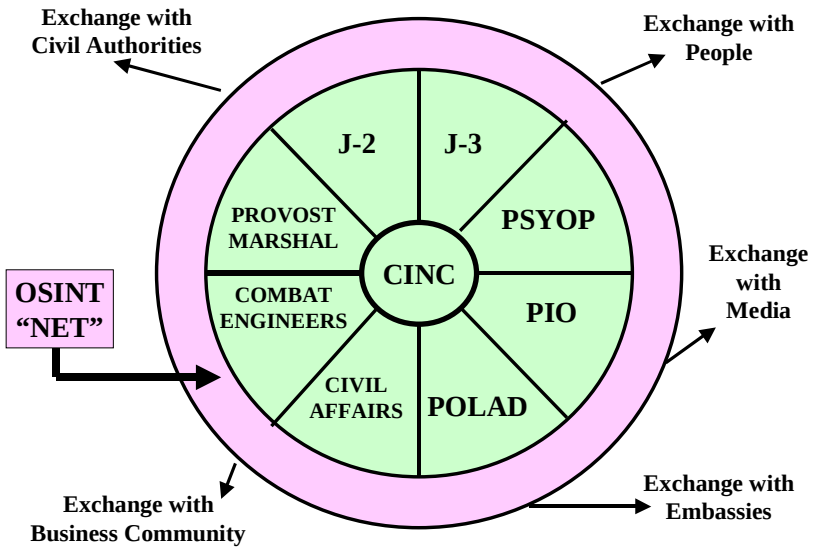


Figure 2 - Utility of OSINT Net for Internal and External Information Exchanges

Definitions

There are four distinct categories of open information and intelligence.

Open Source Data (OSD). Data is the raw print, broadcast, oral debriefing or other form of information from a primary source. It can be a photograph, a tape recording, a commercial satellite image, or a personal letter from an individual.

Open Source Information (OSIF). OSIF is comprised of data that can be put together, generally by an editorial process that provides some filtering and validation as well as presentation management. OSIF is *generic* information that is usually *widely disseminated*. Newspapers, books, broadcast, and general daily reports are part of the OSIF world.

Open Source Intelligence (OSINT). OSINT is information that has been deliberately discovered, discriminated, distilled, and disseminated to a *select*

audience, generally the commander and their immediate staff, in order to address a *specific* question. OSINT, in other words, applies the proven process of intelligence to the broad diversity of open sources of information, and *creates intelligence*.

Validated OSINT (OSINT-V). OSINT-V is information to which a very high degree of certainty can be attributed. It can be produced by an all-source intelligence professional, with access to classified intelligence sources, whether working for a nation or for a coalition staff. It can also come from an assured open source to which no question can be raised concerning its validity (images of an aircraft arriving at an airport that are broadcast over the media).

21st Century Information Operations

OSINT is an essential contextual and foundation element for classified intelligence operations. Overt human sources can help target and validate clandestine human intelligence (HUMINT) sources. Overt broadcast information can be used to better understand covertly collected signals intelligence (SIGINT). Commercial geospatial information, especially wide-area surveillance imagery, can be used to significantly enhance the value of the more narrowly focused covert imagery intelligence (IMINT) capabilities. OSINT can also make contributions to the emerging discipline of Measurements and Signatures Intelligence (MASINT), to Counter-intelligence (CI), and to Operations Security (OPSEC).

OSINT is the major new "force" in 21st Century Information Operations (IO). OSINT is not "new" in that Nations and organizations have always understood the value of legal travelers, direct observation, structured reading, and legal purchases of information services. What *is* new about OSINT is the confluence of three distinct trends: first, the proliferation of the Internet as a tool for disseminating and sharing overt information; second, the consequent and related "information explosion" in which published knowledge is growing exponentially; and third, the collapse of many formerly denied areas.

OSINT is important to coalition commanders and their staffs for another reason: emerging threats, and the lower end of the spectrum of conflict, increasingly demand out-of-area operations and engagement in operations for which classified intelligence support is not readily available. Out of area operations such as humanitarian assistance and disaster relief operations in the countries of Africa or elsewhere along the NATO periphery, are all characterized by complex information needs related to infrastructure, demographics, health, and other matters not traditionally addressed by classified intelligence collection operations.

OSINT is vital to government operations, and especially to coalition operations, for one additional reason: the changing nature of command & control in the 21st Century. In the past, nations and even coalitions relied heavily on a top-down "chain of command" that relied on closed sources to direct generally unilateral actions with short-term time frames. Today, as non-governmental organizations come to the fore and are often the predominant factors in many of the operations that the military must support, the dynamics of both command & control and information have changed.

Within NATO, operations must be planned and executed in a multi-cultural fashion, with bottom-up consensus often being the most effective means of arriving at sustainable decisions. This is particularly true with the vital role played by non-NATO troop contributing nations. Under these circumstances, a common view of the

operating area, formed with the help of validated OSINT is often the most effective means of delivering decision-support.

The remainder of this manual will discuss private sector information offerings, the open source intelligence cycle, and the integration of OSINT into the NATO and prospective PfP coalition operations. OSINT will be a core element of the NATO Future Intelligence Architecture.

Special Note on Operational Security

The most common objection to the use of open sources of information, apart from the general lack of knowledge and funding with which to exploit open sources, relates to Operational Security (OPSEC). This topic is fully discussed within Chapter III. The Open Source Intelligence Cycle makes full provision for OPSEC at every stage, and ample methods exist to conceal the commander's intent, the source of the inquiry, and other sensitive aspects of open source exploitation.

CHAPTER II
PRIVATE SECTOR INFORMATION OFFERINGS

The four pillars to an OSINT strategy are sources, software, services and analysis. The private sector can address all four to some degree. Analysis is the key enabling skill that is essential to the successful integration of OSINT into an all-source intelligence product. While some analysis of open sources can and should be acquired from private sources, those analytical skills necessary to integrate open source derived intelligence must be grown and nurtured within intelligence staffs. Analysis will be discussed further in Chapter III. This chapter is intended to expose the wider audience to the range of OSINT-related products that the private sector are optimized to provide.

SECTION A. SOURCES

Traditional Media Sources

To many, media sources were the only open sources that were familiar prior to the onset of the Internet. These include traditional foreign print and broadcast media, radio and TV as well as the current array of electronically available products. For current intelligence purposes, media sources remain the core capability necessary for an OSINT effort and are available from a variety of providers. Direct wire-service feeds are available. Commercial online premium sources discussed below all provide an array of media sources on a fee for service basis.

While not private sector information providers, the U.S. Foreign Broadcast Information Service (FBIS) and the British Broadcasting Corporation (BBC) Monitoring Service each provide excellent near real-time translation of foreign media sources. In addition, an array of media analysis products supplement the direct listing of foreign broadcasts and provide useful insight into the general character of foreign media reporting on particular issues.

Internet

The Internet has, since 1994, literally exploded on to the world scene and changed forever the manner in which individuals might carry out global research. According to Dr. Vinton Cerf, acknowledged by many to be one of the founders of the Internet, it will grow from 400 million users in November 2000, to an estimated 3.5 billion users by the year 2015.

Apart from this exponential increase in the number of human beings using the Internet, other experts project a double or triple order of magnitude increase in the use of the Internet to connect devices, from geospatial locators in vehicles, to temperature detectors in soda machines, to usage monitors in doorways. The Internet is at the very beginning of its development as a global grid of enormous value to coalition operators, logisticians, and intelligence professionals.

Figure 3 - Internet users by continent (1999)

The Internet has been over-sold in the past. A study by the Community Open Source Program Office (COSPO) within the U.S. Intelligence Community concluded in 1994 that the Internet only contained roughly 450 useful substantive sites, and that 99% of the Internet was not content of intelligence value, but rather pornography, opinion, and advertising. This earlier evaluation of the intelligence potential of the Internet no longer reflects the extensive content that is now available. Some suggest that over 250,000 databases are now available within the "deep web", a great many of which are of potential intelligence value.

While the Internet has grown substantially in value since 1994, the intelligence professional must be very cautious about both over-reliance on the Internet, and about the source bias of materials found there. In general, Internet sources are rarely dated, formatted, paginated, edited, filtered, or stable, even when addressing substantive topics.

The Internet is an "easy out" for operators and other consumers of intelligence. It is an attractive option for commanders and staff in a hurry. If intelligence professionals do not demonstrate that they monitor and exploit the Internet, and/or if intelligence professionals make it too difficult for consumers to obtain usable all-source intelligence, the Internet represents a "threat" to the existing intelligence process. Increasingly, intelligence professionals must act to place information that is widely available on the Internet into its proper context – either confirming its validity or disputing the information based on classified collateral reporting.

In general, the Internet today provides two benefits to the coalition professional: first, as a means of rapidly communicating with counterparts around the world, primarily to exchange unclassified information and professional insights; and second, as a means of rapidly accessing both free and premium (fee paid for access) information sources. However, the Internet also has its dangers. Electronic mail and attached documents comprise a permanent record in cyber-space, and the sender has little control over subsequent dissemination and exploitation.

OSINT Professional Note: A number of advanced search tools are available that complement the variety of search engines that are freely available on the Internet. OSINT managers should remain abreast of developments in the field of Internet tools and integrate appropriate tools, as they become available, into their OSINT process. An example, its basic form available free or in an advanced version at a small cost, is a meta-search engine that combines the best features of multiple search engines, while also permitting subsequent searches for new information (remembering what has already been seen). Download this program from www.copernic.com.

Commercial Online Premium Sources

There are numerous commercial online premium sources, that is, sources that charge either a subscription fee or a usage fee for access to their information. It is essential that every professional understand the availability and the value of commercial online premium sources. They represent decades worth of editorial selection,

authentication, formatting, indexing, abstracting, and presentation management. In general, source material obtained through a commercial online premium service has been created by a reputable commercial enterprise subject to scrutiny and the judgment of the marketplace. In Figure 4, we discuss the three best known to governments and corporations. There are many others, some unique to Europe or Asia. Each professional is urged to consult his or her librarian or his or her OSINT collection manager to gain a better understanding of what their options are for high-quality commercial information relevant to their action responsibilities.

In general, and in part because of the high cost of mistakes or unnecessary retrievals, all commercial online premium services should be searched by those staff with sufficient training on the database and a thorough understanding of its pricing structure. Even commands with flat-fee pricing should be aware that their next contract will be increased in price based on actual usage during the current flat-fee period. Alternatively, an option is to gain access to commercial sources via the services of a professional librarian or commercial information broker. Most professional information brokers, such as those belonging to the Association of Independent Information Brokers (AIIB), specialize in either LEXIS-NEXIS or DIALOG. There are distinct advantages in contracting a searcher who has detailed familiarity with the very arcane search command characteristics of these two services. In the case of Factiva this is less vital but can still make a big difference in both the success of the searchers, and the cost of the searches.

FACTIVA	LEXIS-NEXIS	DIALOG
www.factiva.com	www.lexis-nexis.com	www.dialog.com
Best web-based user interface, easiest means of searching all available publications. Archive of publications varies but typically provides several years worth of historical file. Includes Jane's Information Group material as well as BBC transcripts. Does not include FBIS information.	Two separate channels, one focused on legal sources including public records (primarily in the United States but very helpful in tracing real estate, aircraft, and water craft including international ships), the other focused on news sources but offering archive access, i.e. ability to reach back several years or more on any topic.	A very large collection of various commercial offerings that can be searched "by the file". Especially valuable for access to conference proceedings, academic and policy journals, dissertations, book reviews, and the Social Science Citation Index (SSCI). The latter is ideal for finding and ranking individual experts, to include identification of their official address.
Flat fee or actual cost pricing.	Flat fee, actual cost, or pay as you go credit card pricing.	Flat fee, actual cost, or pay as you go credit card pricing.

Figure 4 - Leading Commercial Online Premium Sources

OSINT Professional Note: Always ask for search results in electronic form, these files can more easily be shared. Copy the results into a Word document. Add pagination. Add a title page and a blank table of contents page. Sort the items into larger categories (e.g. Political, Military, Economic) and label the categories as "Heading 1". Then go through the document label each individual headline as "Heading 2". These headings are choices in the style bar at the upper left that generally says "Normal". Finally, go to the Table of Contents and use the Insert, Index and Tables, Table of Contents choices to insert a table of contents. If desired, use the Replace function to find and make bold all of the original search terms.

Other Forms of Commercial Online Information

There is a vast range of commercial sources available through direct subscription, both on the Internet and in the form of hard copy or CD-ROM publications. Table 1 below identifies just a few sources of common interest to military commanders and their staff. There are many more than those listed here. SACLANT has undertaken to develop and maintain a common NATO inventory of open sources and access points to which RFIs can be directed. This can be found on MCCIS at www.saclant.nato.int/intel. Work continues to progress on a concept of operations for establishing broad NATO access to such sources at the most competitive prices possible.

Table 1 - Examples of specialized commercial information

Grey Literature

Grey literature is that information that is both legally and ethically available, but only from specialized channels or through direct local access. It is generally understood as that information whose distribution is not controlled by commercial publishers, and/or that information that is not published, distributed, catalogued or acquired through commercial booksellers and subscription agencies. Grey literature includes working

papers, pre-prints, technical reports and technical standards documents, dissertations, data sets, and commercial imagery. Producers of grey literature include: non-profit and educational organizations; commercial enterprises creating documents for internal use as well as for clients and suppliers; local, state, and national government agencies producing materials for internal use as well as for citizens and vendors, and; a wide variety of informal and formal associations, societies, and clubs. Examples include university yearbooks, yacht club registries, corporate trip reports, and personal notes from public events that are posted to a public bulletin board.

Overt Human Experts and Observers

The ultimate open source is a human expert or human observer with direct experience. In many places of the world, Africa, for example, it is not possible to obtain published information on specific locations or conditions. For many topics, even those with great quantities of published information, it is not possible to find exactly what is needed even when the time and money is available to collect, process, and analyze all available published information. The human expert is often the most efficient and the most inexpensive means of creating new open source intelligence that is responsive to a specific requirement from the commander or his staff.

The identification and interviewing of those with direct on-the-ground experience is also a valuable means of ascertaining "ground truth." It merits comment that official communications from organizations, and most media reporting, tend to rely on second-hand reports. Unless the information is meticulously sourced and from a very trusted source, expert judgment or observation more often than not it will be less reliable than direct human expert judgment or observation.

OSINT Professional Note: There are essentially four ways to get to expert humans. The most effective means is through citation analysis using the *Social Science Citation Index* (SSCI) or the *Science Citation Index* (SCI). These can both be accessed at www.isinet.com/isi. This generally requires a specialist searcher with access to DIALOG for the SSCI or to the Scientific and Technical Network (STN) for the SCI. The second means is through professional associations such as listed in the *International Directory of Associations* published by Gale Research, or as found through a copernic.com search of the Internet. The third means is by doing a Factiva.com search and identifying experts or "talking heads" that have been quoted in the media on that topic. Last, and often the least efficient, is through a labor-intensive series of telephone calls to various known government agencies or official points of contact. As a general rule, it is best to do a comprehensive professional search for international experts with the most current knowledge, rather than relying on the in-house focal points or whomever might be casually known to in-house points of contact.

Commercial Imagery

The commercial imagery industry continues to mature with the launching in recent years of a number of satellites that offer militarily significant capabilities. One-meter

resolution electro-optical imagery available to the private sector is not only possible now but also likely to be *de rigueur* in the future. Table 2 illustrates some of the military applications of 1-m commercial imagery. By 2003, at least eleven private companies expect to have high-resolution commercial remote sensing satellites in orbit. Their products will be available to whoever has a credit card. While this will bring new capabilities to friend and foe alike, commercial imagery provides unique opportunities for NATO as well. Unbridled by security constraints, which limit the use of imagery derived from military satellites, commercial imagery acquired by NATO can be freely distributed within the constraints of copyright agreements with the original provider. This provides a host of options regarding cooperation with broader coalition partners who do not have access to NATO classified information.

Target *(note a)*	**Detection** *(note b)*	**General ID** *(note c)*	**Precise ID** *(note d)*	**Description** *(note e)*	**Technical Analysis**
Troop units	**6.0**	**2.0**	**1.20**	**0.30**	**0.150**
Vehicles	**1.5**	**0.6**	**0.30**	**0.06**	**0.045**

Railroad yards and shops	**15.0-30.0**	**15.0**	**6.00**	**1.50**	**0.400**
Terrain	**--**	**90.0**	**4.50**	**1.50**	**0.750**

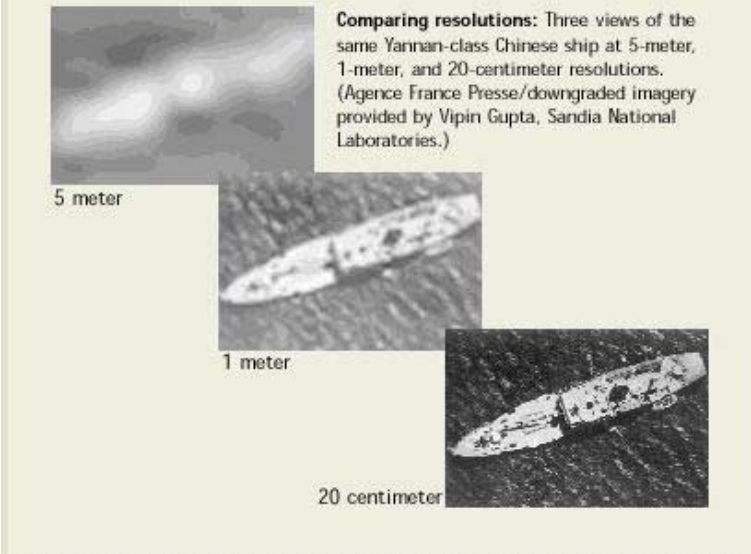
Notes:

a. The table indicates the minimum resolution in meters at which the target can be detected, identified, described, or analyzed. No source specifies which definition of resolution (pixel-size or white-dot) is used, but the table is internally consistent.
b. Detection: location of a class of units, object, or activity of military interest.
c. General identification: determination of general target type.
d. Precise identification: discrimination within a target type of known types.
e. Description: size/dimension, configuration/layout, components construction, equipment count, etc.
f. Technical Analysis: detailed analysis of specific equipment.

Table 2 - Approximate Ground Resolution in Metres for Target Detection, Identification, Description and Analysis

Source: Yahya A. Dehqanzada and Ann M. Florini. *Secrets for Sale: How Commercial Satellite Imagery Will Change the World*. Washington D.C.: Carnegie Endowment for International Peace, 2000.

The individual satellites are currently limited by poor revisit times to specific targets. This factor is mitigated by the growing "virtual constellation" of commercial remote sensing satellites that is comprised of the collective resources of all of the available private companies. The Western European Union (WEU) satellite center has grown its capability through the concept of exploitation of all available commercial resources rather than restricting to merely European sources.



Comparing resolutions: Three views of the same Yannan-class Chinese ship at 5-meter, 1-meter, and 20-centimeter resolutions. (Agence France Presse/downgraded imagery provided by Vipin Gupta, Sandia National Laboratories.)

Figure 5 - Comparative imagery resolutions

In addition to electro-optical sensors, Synthetic Aperture Radar (SAR) imagery capability is improving significantly. SAR imagery relies upon the analysis of a signal transmitted in the microwave part of the electromagnetic spectrum and the interpretation of its return signal. Unlike electro-optical systems, these sensors are not limited to daylight operations. Because they have an active sensor, they can image a target in day or night, in any weather, through clouds and smoke.

While current systems are capable of 8-meter resolution, the next few years will see commercial SAR satellites providing 1-meter resolution. These systems will be able to provide a dependable source of militarily significant commercial imagery to NATO forces as well as to our adversaries.

A number of NATO nations purchase commercial imagery to support their own national imagery requirements. In many cases, these images can be redistributed freely. While NATO commands are able to purchase commercial imagery themselves, national sources of imagery should be consulted, as part of any collection effort, to ensure that commercial imagery needs cannot be addressed through existing sources.

The "virtual constellation" of commercial remote sensing satellites will ultimately be able to provide a target revisit schedule that will increase its reliability as a source of imagery. Until that time, the vast archive of commercial remote sensing images remains a rich source of historical data that can be acquired fast and at low cost. Historical data is optimized for mission planning, mapping and humanitarian support operations when detailed knowledge of infrastructure is essential.

Defining Source Access Requirements (Dangers of Pay-per-View)

It is a relatively easy endeavor to identify private information sources that can support the information needs of an OSINT programme. With the proliferation of restricted and open access Intranets, there are great pressures to place all information acquired onto web-based dissemination systems.

While single copy licenses to information

sources are typically attractively priced, multiple user licenses increase in price. License costs are generally a factor of the number of users that have access to the information. To place information directly onto servers without the knowledge and consent of the information provider is a violation of copyright laws.

An option to reduce costs is to determine the information needs of the organization based on communities of interests. Some information is required by all staff and merits a general site license. Other information is of interest to a more restricted audience. Lloyd's shipping data, for example, may be of general interest to a wider audience but of job specific interest to a select group of analysts. The purchase of a limited site license and the use of restricted access within the Command's Intranet will greatly reduce license costs yet still provide the information in the most effective manner. Finally, ad hoc information requirements may be addressed with the acquisition of single copies of key information sources.

As a general rule, there are few information sources that are required by all members of a staff. Restricting access to some sources will increase the range of open sources that are available for purchase within an organization's OSINT budget. Careful planning and the identification of the logical communities of interest for individual open sources is a reasonable approach to manage scarce resources.

SECTION B. SOFTWARE

Software Hierarchy

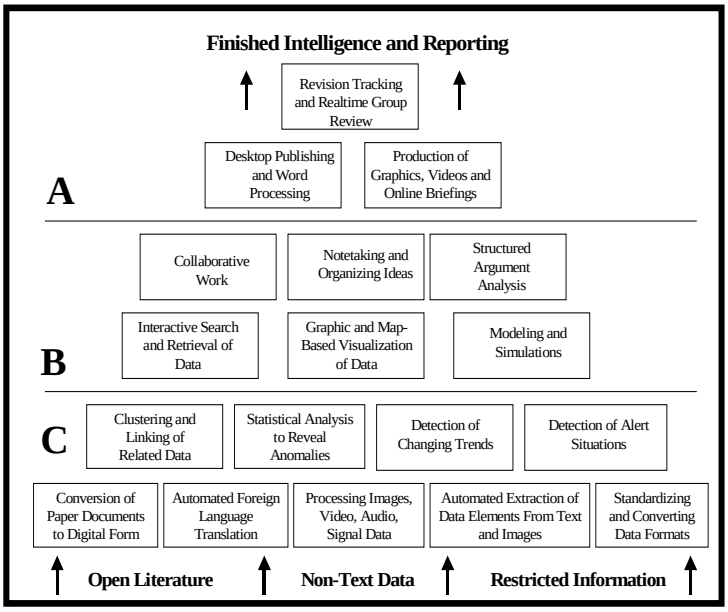


Figure 6 - OSINT Software Hierarchy

Above is an illustration of the eighteen distinct software functionalities that have been identified as being necessary for the optimal processing of open sources of information by any analyst—these would comprise the desktop "toolkit."

Section A functionalities include publishing and production management functionalities. Section B functionalities combine

collaborative work tools with data visualization and manipulation tools with thinking tools: modeling and simulation and structured argument analysis. Section C functionalities combine tools for the automated pre-processing of data once it is digital, and with tools for converting hard copy and multi-lingual or multi-media information into a single digital standard.

Unfortunately, the state of the software industry in general, and of desktop software in particular, is such that today it is not possible to integrate all of these functionalities at an affordable cost. A major obstacle to progress is the existing industry practice of concealing and constantly changing Application Program Interfaces (API). This means that third party software producers desiring to have their offerings work with another major product, must undertake lengthy and often expensive negotiations in order to be shown the proprietary API. Software today is still not "plug and play", and it is unlikely to become fully intergratable "out of the box" until standards of stability and transparency for API are established.

Having said this, it is possible to identify several software packages of some value to the open source intelligence analyst or the action officer working with open source intelligence.

SECTION C. SERVICES

Collection Services

Collection services include online collection (searchers that specialize in Internet, deep web and premium commercial online source exploitation); off-line grey literature or document acquisition; telephone surveys and electoral or other forms of polling; private investigations and human intervention services ("boots on the ground"); and aerial surveillance or reconnaissance services.

Processing Services

Processing services include data conversion from hard-copy or analog to digital, indexing and abstracting of hard-copy or soft-copy textual data or images, interpretation and annotation of imagery or signals, database construction and stuffing, and complex modeling & simulation projects with the best ones including geospatial and time-based visualizations.

When integrated with well-planned open source collection and the right analytical expertise, complex processing services can yield substantial dividends by compressing large amounts of data into manageable tailored products that address specific intelligence requirements.

Analysis & Production Services

A wide variety of commercial and academic organizations offer diverse analysis and production services. As a general rule, the best value is found through the hiring of single individual experts with no overhead, rather than through broad contracts with organizations that then adds a substantial fee for their considerable overhead expenses.

The very best value results when niche collection, niche processing, and niche analysis services can be "mixed and matched" to obtain precisely the desired results. The very worst value comes when an organization is hired because of a convenient contract, they do not have a niche expert, and choose to dedicate an

analyst that does not bring sufficient experience or skill to the task.

Industry leaders can best be identified with reference to citation analysis and familiarity with their product set. This is best accomplished through the identification of other organizations with similar intelligence problems and exchanging information concerning those validated information vendors that they employ. Web-site analysis is another tool, which can be applied to vet the capabilities of a potential information vendor.

Services Examples

Data Conversion	ACS Defense www.acsdefense.com
Database Construction & Stuffing	ORACLE www.oracle.com
Document Acquisition	British Library Document Centre http://www.bl.uk/services/bsds/dsc/

Signals Processing	Zeta Associates Incorporated www.zai.com
Telephone Surveys (Primary Research)	Risa Sacks & Associates www.rsacksinfo.com

Table 3 - OSINT Related Services

As a general rule, there are no "portal" companies that serve as honest brokers for helping governments "mix and match" best in class niche providers at the most economical cost.

CHAPTER III
THE OPEN SOURCE INTELLIGENCE CYCLE

SECTION A. OSINT PLANNING AND DIRECTION

Overview

Whether one is going after open source data, information, or intelligence, there is a proven process of intelligence, the intelligence cycle that will yield good value when applied. The open source intelligence process is about discovery, discrimination, distillation, and dissemination—the 4 Ds (Figure 7). This analytical approach is applied to the traditional single source intelligence cycle. A good understanding of the open source intelligence cycle makes it possible to access and harness private sector knowledge using only legal and ethical means, generally at a very low cost in comparison to covert technical or clandestine human collection. Since many requirements that are urgent for the commander and their staff may not qualify for nor be appropriate for secret collection methods, the open source intelligence cycle is in fact *vital* to NATO planning and operations. As will be seen in the following discussion, OSINT is an emerging discipline and the emphasis will often be on informal coordination rather than formal tasking.

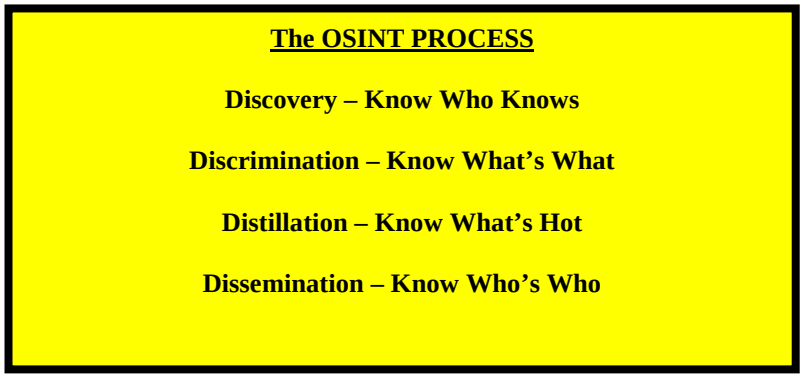

Figure 7 - The OSINT Process

Organizations and Responsibilities

The commander is ultimately responsible for establishing the Essential Elements of Information (EEI) and for applying the resources necessary to satisfy them. Open source intelligence is *not* necessarily the responsibility of, or available from, national-level intelligence organizations. While the intelligence staff typically acts as the staff principal for OSINT activities, other staffs are frequently well placed to both collect open sources and to facilitate the further development of sources on behalf of the Command. The subordinate commanders for Civil Affairs, Public Relations, Military Police, and Combat Engineering may often be the best channels for seeking out OSINT, and can comprise an informal advisory council to the commander.

OSINT sources include, but are not restricted to:

- **National-Level Intelligence Organizations**. Although they are not responsible for satisfying the commander's needs for OSINT, national-level intelligence organizations may have relevant open source information that can be provided. Some countries, such as The Netherlands, United Kingdom, Denmark and Norway, are exceptionally competent in this area and have fully integrated OSINT into their all-source collection and production environments. Others may have selected units that can be called upon, but have not yet mastered this discipline.

- **Diplomatic Missions**. The established diplomatic missions of the various member nations are often the best source of OSINT, at little cost, if they are approached by one of their nationals acting in an official capacity on behalf of the commander. Such missions are under no direct obligation to respond, but informal coordination may yield good results.

- **Chambers of Commerce**. Many of the member nations have Chambers of Commerce and these often have established small communities that bring the general managers and key business executives from their national firms in any given country together. On an informal basis, with clear disclosure of the commander's interest, useful OSINT may be acquired. This is particularly true in deployed areas.

- **Non-Governmental Organizations**. The International Committee of the Red Cross (ICRC), Doctors Without Borders, and the many elements of the United Nations as well as the many international relief and charity organizations, have deep direct knowledge that can be drawn upon through informal coordination.

- **Religious Organizations**. Many Non-Article 5 Operations have very substantial human mass migration and ethnic conflict aspects as witnessed during Operation Allied Force. These issues are often best understood by religious organizations. Organizations such as The Papal Nuncio and the local Opus Dei, the B'nai Brith, the Islamic World Foundation, and other equivalent religious organizations are an essential source of overt information and expert perceptions

Requirements Definition

The greatest challenge for the commander will be the establishment and maintenance of a rigorous and disciplined process for defining the requirements to be addressed through open sources. The common attitudes of "tell me everything about everything" or "if I have to tell you what I need to know you are not doing your job" represent unworkable direction.

Commanders and their staff must carefully evaluate the specific information needs in the context of their concerns and their plans and intentions, and they must articulate, in the narrowest possible way, precisely what they want to know and why. The commander's operational intent is as vital to the intelligence professional as it is to the operations professional. Only by understanding the context and direction of the commander's requirements, can a truly focused and flexible collection effort be undertaken.

OSINT is the most fundamental and fastest means of satisfying basic informational

needs, including needs for historical background, current context and general geospatial information. Each commander should distinguish between their tailored intelligence requirements in support of their future planning and the basic information requirements that will permit operational and logistics and other special staff planning (e.g. Civil Affairs) to go forward. OSINT is highly relevant to both kinds of intelligence support.

Evaluation and Feedback

Planning and direction is a continuous process. The commander and their staff must digest, evaluate, *and provide feedback on* all received intelligence, whether open or classified. As open source intelligence is received and reviewed, it must be shared with staff principals and subordinate commanders, evaluated, and the results of the evaluation passed directly to the staff element responsible for coordinating OSINT support to the commander.

SECTION B. COLLECTION

Overview

The heart of intelligence collection is research – it is the matching of validated intelligence requirements to available sources with the aim of producing a product that answers a valid need. Once an intelligence need has been identified, open sources should be reviewed by intelligence staffs to determine if that intelligence need can be satisfied through those resources organic to the intelligence staffs, those resources that the staff can access, if an RFI to nations is required, or if a combination of these approaches is required.

Collection requires the translation of an intelligence need into an intelligence requirement – an action plan to answer that need. A collection strategy is developed to tap available sources. Optimal sources are selected and the information is collected. This generic collection approach is equally applicable to classified sources as it is to open sources.

In the NATO context, OSINT is a contributing source to an all-source intelligence effort. Open sources are used to compliment the existing classified intelligence and can be collected on a specific area. OSINT-derived products are created to answer a specific intelligence need to which open sources are best optimized. While RFIs from intelligence users typically generate collection efforts, Table 4 illustrates the three types of producer generated intelligence collection and production requirements.

These three categories outline the way in which an internally directed OSINT

Analyst-driven	**Based on knowledge of customer and issues**
Events-driven	**In response to time-sensitive relevant events**
Scheduled	**Periodic activities to document and update target status**

Table 4: Types of Producer-Generated Intelligence Collection and Production Requirements

Source: Arthur S. Hulnick. "The Intelligence Producer-Policy Consumer Linkage: A Theoretical Approach." Intelligence and National Security, Vol. 1,No. 2, (May 1986)

collection strategy should be developed. Only those products that support the intelligence staff's mission should be produced. The range of open information that is available both freely and commercially will swamp the analytical capacity of any intelligence staff regardless of size. Therefore, effective management must include the avoidance of production without a specific purpose. While not advocating a "make work" approach to intelligence, producer-generated collection builds skills, evaluates sources and increases capabilities necessary to address future RFIs and production requirements.

An analyst is often best placed to determine what product is required to address the past needs of the intelligence user. Proactive collection and management to make effective use of emerging information should be encouraged. This could include the tailoring of a newly available public report that addresses an established intelligence need into a format of use to an intelligence user.

Rapidly changing events can drive the production of new products. A military coup or an environmental crisis could presage increased NATO interest in an area of non-traditional interest. In the absence of national intelligence production shared with NATO, open source collection may be the best means with which to begin to build an intelligence picture for the command.

Less dramatic changes to the international environment may also require open source collection. Seasonal changes in a particular region may lead to population migration. These periods are known well in advance and lend themselves to scheduled production of necessary intelligence products.

Chapter II reviewed private sector information offerings. Chapter III focuses on the methods to be applied by any NATO unit to exploit those offerings, while not recommending any specific source, software, or service. What is important is that every NATO unit is conscious of the overall process, the alternative means for obtaining and exploiting OSINT, and the value of OSINT as part of the all-source intelligence cycle. Figure 8 below is provided a high-level view of the elements of the OSINT collection process.

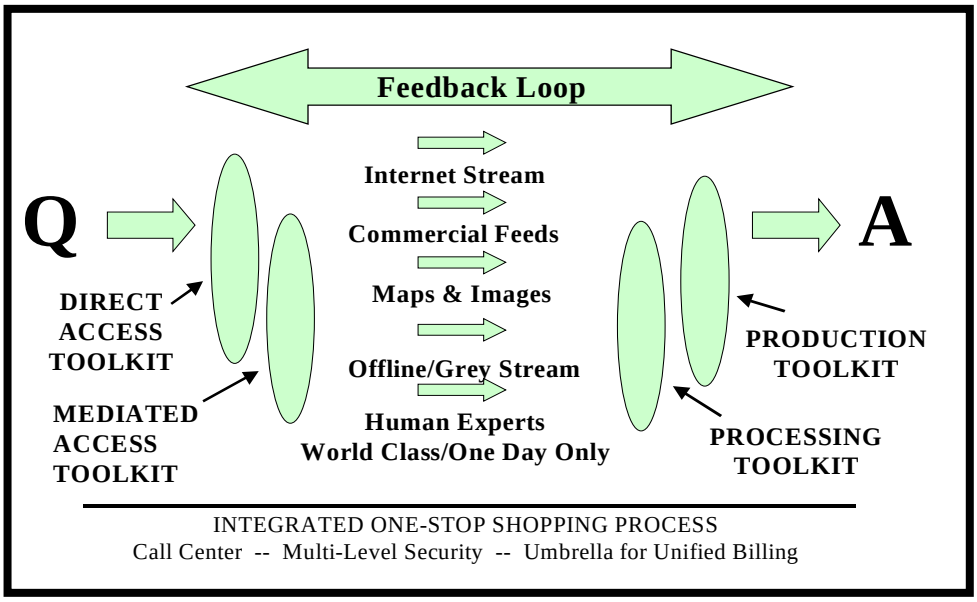

Figure 8 - OSINT Collection Process

Knowing Who Knows

During periods of stability as well as crisis, it is incumbent upon intelligence staffs to establish and nurture sources that will help satisfy information requirements. It is vital that the OSINT professional, known in some governments as Open Source Officers (OSO), focuses initially on "knowing who knows" – the ability to rapidly identify subject matter experts on topics of direct relevance to the commander's mission and to seek information from them.

An approach favoured by some is the concept of collecting sources not information. While the array of available open sources is staggering, the ability to focus collection quickly on an emerging issue of intelligence interest is the key capability. Rather than having a stale open source product to draw upon, the ability to rapidly direct collection on an issue, identify the leading experts on the field and either draw upon their most recent work or contact them directly is the most effective use of an OSINT capability.

Therefore, a standing collection priority should include a preliminary inventory of subject-matter experts (SME) within the parent commands and its subordinate, adjacent, and higher commands, but should then extend further, throughout the parent government and into the national private sector. The business community with its international chambers of commerce, the academic community with its various professional associations, and the non-governmental organizations including the peace institutes resident in many countries, are all vital points of reference.

The command OSO is, in essence, an information attaché to each of these elements, and must always act with the highest standards of overt decorum and propriety. This must include a firm grasp of both the private sector's rights and obligations with respect to copyright and the protection of intellectual property, and NATO's concerns with regard to OPSEC.

Collection Discipline

There is no faster way for an OSO to lose his commander's respect than to try to do too much, and end up taking too long to produce simple answers. Time management, and a very disciplined approach to the art and science of OSINT collection, is the key to every success.

The ever-increasing array of open sources provides a rich environment for unbridled research. OSINT managers must ensure that their staffs are aware of the degree of detail required for each OSINT product being prepared. The Internet and commercial premium online sources are seductive to the analyst. Within any OSINT effort, time spent in collection is always at the expense of analysis. The desire to continue with the

OSINT Professional Note: A recommended timetable for a standard OSINT collection and analysis task is provided below:

15 Minutes	Requirements Definition. Ensure an understanding of commander's intent.
30 Minutes	Internet Collection. Use search tools, rapidly identify top ten sites and review.
15 Minutes	Internet Table. Create Internet Table for future use and for customer's reference.
60 Minutes	Commercial Collection. Use fee sources, identify top 20 items for exploitation.
60 Minutes	Analysis. Read, understand, evaluate, and structure collected information.
60 Minutes	Production. Carefully create an analytical summary, table of contents, and slides.
4 Hours	Total time required to create any OSINT report using only internal resources.

collection and acquisition of open sources at the expense of their evaluation and presentation as an analytical product reduces the effectiveness of the OSINT contribution to the all-source effort. In few other fields is the mantra that "perfection is the enemy of good enough" more appropriate than it is for open source collection. Collection efforts can be reduced if time spent in the evaluation of the reliability and objectivity of specific open sources does not have to be replicated each time an analyst begins a project. OSINT managers should ensure that their staff maintains a dynamic compilation of the open sources that they exploit for specific issues. This reference aid will serve as the starting point for subsequent analytical tasks.

Collection Issues

There are several collection issues that always surface whenever commanders and staff first consider OSINT as a structured discipline. These include OPSEC, Copyright Compliance, Foreign Language Shortfalls, and External Networking.

Operations Security

- OPSEC is easily achievable in the OSINT environment through two measures: first, the concealment of the origin of the search through the use of trusted intermediaries; and second, the utilization of normal commercial Non-Disclosure Agreements (NDA) when necessary to protect direct discussions of a commander's concerns and intentions.

- In general, most OSINT inquiries will be amply protected by existing processes, but when appropriate, a trusted local national with information broker skills can be hired (or a Reservist utilized) to distance the inquiry from the command. It is a misconception to believe that any discussion with OSINT providers must be itself open.

- The private sector is accustomed to protecting proprietary and commercially confidential discussions. A standard private sector NDA is just as a good as a government secrecy agreement, with the added advantage that the private sector partner has a financial motivation for honoring the NDA—they want more business and discretion is part of what they are selling.

Copyright Compliance.

- In the past, many governments have felt that copyright compliance did not apply to their official needs, and some governments have resorted to the classification of open source information as a means of concealing their routine violation of private sector intellectual property rights

- It is now essential for all governments, and for all NATO elements, to learn how to properly comply with applicable copyright provisions. This is important for two reasons:

  - To maintain the highest standards of legal and ethical behavior among all NATO elements;

  - More often than not, OSINT must be shared with external private sector parties (e.g. humanitarian assistance organizations) or used as a means of exchange (pooling information on Kosovo, for example). Thus copyright compliance is a vital means of maintain future *flexibility* in the exploitation of the OSINT available.

Foreign Language Shortfalls.

- Despite the multi-cultural and multi-lingual nature of the NATO alliance, many out-of-area contingencies require

foreign language skills that are not readily available with the NATO force, or that can be identified quickly and provided with security clearances.

- Over time it is vital that each commander identifies foreign language skills as well as shortfalls and that these be consolidated and evaluated as part of the larger NATO Future Intelligence Architecture plan.

- Understanding international terrorism, insurgency, and violent internal political opposition movements, to take one example, requires competency in a number of foreign languages to include: Arabic, Catelan, Danish, Dari, Dutch, English, Farsi, Finnish, French, German, Indonesian, Irish, Italian, Japanese, Korean, Kurdish, Kurmanji, Norwegian, Pashto, Polish, Portuguese, Russian, Serbian, Spanish, Swedish, Tamil, Turkish and Urdu.

- Many of the required capabilities are within the competence of national intelligence organizations but these capabilities are unlikely to be made available to NATO commands for the exploitation of OSINT.

External Networking.

- There are four obstacles to external networking relevant to NATO competency in OSINT.

- First, there is a lack of knowledge about who the real experts are on various regional and topical issues.

- Second, there is a fear of revealing the question as an official inquiry—in some countries; there are even prohibitions against direct contacts between intelligence personnel and private sector experts.

- Third, there is the lack of funding for compensating subject-matter-experts—everything must be done on a barter or exchange of favors or information basis.

- Fourth and finally, the existing command & control, communications, computing, and intelligence (C^4I) architectures tend to prohibit routine access to the Internet, and often make it difficult if not impossible to migrate unclassified information from the Internet into classified databases.

All of these obstacles can be overcome. A major outcome of the new NATO OSINT initiative will be the definition and resolution of each of these obstacles.

Nuances of Open Source Collection

The Internet, although it will never be a completely trustworthy source for information, has become the *de facto* C^4I backbone for everyone other than the military. It is essential that our intelligence, operations and logistics staffs develop new doctrine and new methods for fully exploiting the data sources and the human experts that are easily accessible through this medium. As NATO deals with more and more non-traditional threats and more and more out-of-area as well as civil stability scenarios, OSINT will become a much more important element of the all-source intelligence solution. It is vital that every NATO commander and relevant staff member begin now to understand and plan for their OSINT needs.

Training in open source exploitation is relevant not only to the intelligence professionals, but also to all relevant staff

members who need access to open sources of information. OSINT is not the exclusive purview of the intelligence profession. The intelligence professionals should be available to reinforce the commander and their staff, but as a general rule, if a staff principal can answer his own information requirement exclusively through those open sources available to him, then that staff principal that should manage his own collection effort.

Intelligence staffs should enable all staff elements to access relevant open sources as directly as possible. Intelligence staffs should serve to facilitate the flow of OSINT and open source material while providing source evaluation and guidance. Applying this process will enable many potential RFIs to be self-satisfied and thus not submitted. A robust OSINT programme can reduce the number of unnecessary RFIs that bog-down the all-source intelligence staff with information requests that can otherwise be satisfied.

While each commander will have their preferred means of managing OSINT, what is required is that they have a formal point of contact for OSINT matters, an established process, and that they ensure that OSINT is fully integrated into every aspect of their command & staff operations.

The Internet, despite its current and projected growth, is primarily a vehicle for open collaboration, rather than a repository of knowledge. Commercial online sources such as Factiva, DIALOG, LEXIS-NEXIS, STN and Questel-Orbit have huge repositories of information that have been professional selected, evaluated, indexed, abstracted, structured, and made available in a very stable format with authoritative sourcing, formatting, and dating.

In many cases, the information provided through these services have been “peer reviewed” – an exhaustive evaluation process by established leaders in the field of study to ensure the accuracy of the information and the rigor of the research. The Internet is not a substitute for premium fee-for-service commercial online databases, and it is vital that no NATO element falls prey to this illusion.

Each commercial service, as discussed briefly in Chapter II, has its own strengths and weaknesses. A robust OSINT capability should include the understanding of and the means to exploit each service accordingly. Some are best for current news, others for legal records, and others for access to conference proceedings and dissertations.

According to some OSINT experts, only a fraction of known knowledge is available online, either through the Internet or through the commercial online databases. Grey literature, the limited edition publications that are not available through normal commercial channels, comprises a vital "middle ground" between online knowledge and human expertise capable of creating new knowledge in real time. Therefore the NATO OSINT process includes the inventory and evaluation of grey literature sources, and the development of a strategy, a budget, and a process for assuring that grey literature sources are fully integrated into the NATO future intelligence architecture.

Finally, there is the human element. As OSINT doctrine is developed, it would be helpful to think of three distinct forms of overt HUMINT support to NATO. First and foremost are internal subject-matter-experts. These are scattered across commands and within various elements of the member nations’ governments. Second are the private sector experts who have achieved a favorable reputation based on their proven record of accomplishments and publications. Thirdly, there are "local knowledge" experts, including legal travelers and local residents that are rarely exploited by resident defense attachés for lack of time or funding with which to reimburse individuals for their time and expense.

New means must be found for defining

which local knowledge and local observation is needed, and for combining direct observation by qualified NATO personnel, with out-sourced overt collection and production.

SECTION C. PROCESSING AND EXPLOITATION

Overview

After the vital role played during the collection portion of the intelligence cycle, when "knowing who knows" and being able to "mix and match" niche providers of varying pieces of the OSINT solution is essential, it is in the processing and exploitation portion of the cycle that the OSO really makes a mark.

Open sources, just like clandestine or covert sources, require the application of human judgment in order to sort out the important from the unimportant, the timely from the dated, the relevant from the irrelevant, the trusted from the untrusted. As so much of OSINT is *not* in digital form, hands-on human translation and evaluation are the most important part of processing and exploitation.

Without a dedicated set of automation tools to facilitate the processing of open source information, OSINT production will continue to be reliant upon *ad hoc* software solutions and rigorous analytical effort.

Analysis

When working from open sources, there is considerable danger for the analyst to be susceptible to unwanted biases and deception from open source authors. While it is never wise, nor an acceptable practice, to attribute as fact intelligence solely because it was received from a national intelligence agency, in those cases, the analyst is able to make certain judgments regarding how that agency managed its information prior to releasing its report. This is not always true for open sources. It is essential that the analyst remain mindful of and determine the origin of the information that has been gathered and the degree of trust that can be assigned to it. Appendix C provides a list of some common misperceptions and biases.

In the production of OSINT reports, it is crucial that the reader be aware of what is known and what is being speculated about. The analyst should always be careful to distinguish between information and fact. If the original source material is not provided

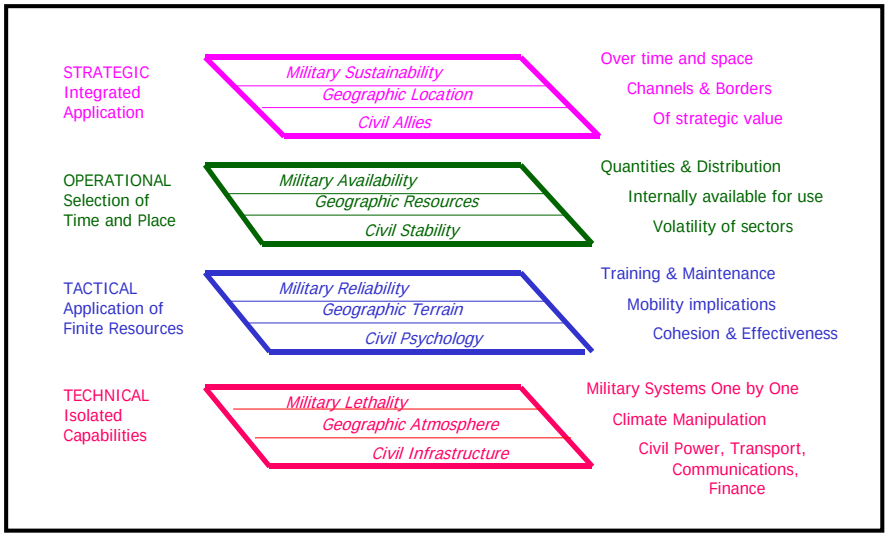

Figure 9 - Levels of Analysis Model

in full text, it is important to make reference to it and provide an assessment of the source's credibility.

If at all possible, the original sourcing information should never be separated from the open source reporting. A complete description of where the open source information was acquired, the identification of the source, the timing of both the production of the open source information and the timing of its acquisition—these all comprise fully half the value of an OSINT product. Without the sourcing pedigree, the open source substance must be considered suspect and of minimal value to the all-source intelligence analysts or the operations or policy consumers being supported.

It is also helpful when processing open source (or classified) information manually to have in mind a clear model of analysis that distinguishes between military, civil, and geographic information, and also between the levels of analysis—strategic, operational, tactical, and technical—for the threat *changes* depending on the level of analysis. This also helps the analyst to recognize gaps in their collected information, and the relationship between different types of information. One such model is provided in Figure 10 above for illustrative purposes.

Web Site Authentication and Source Analysis

Content on the Internet continues to grow at logarithmic rates. The Internet has become an essential enabling element for commerce. It is also facilitating other forms of human interaction across borders which two decades ago were unimaginable. The intelligence value of information found on the Internet is extremely variable. The dangers of creating misleading analysis through the bleeding of unevaluated biased information into the all-source intelligence picture are ever present. Therefore, the OSINT analyst must take steps with each open source to evaluate its reliability. The standard criteria for evaluation of web-sites are as follows:

Accuracy.

- Is the information that is provided consistently accurate based on other sources? The OSINT analyst is able to compare information provided from the web-site with validated all-source intelligence. Benchmarking open sources against validated all-source intelligence assists in assessing the likely accuracy of other information contained on the web-site to be used to address intelligence gaps.

Credibility & Authority.

- Does the web-site clearly identify itself? Is there merely an E-mail address or a full name, address and telephone number. *Sam Spade* (www.samspade.org) is a web service that provides various online tools to validate a web-site. These include diggers that trace routes used by the web-site. (See Web-site Analysis Guide on the following page).

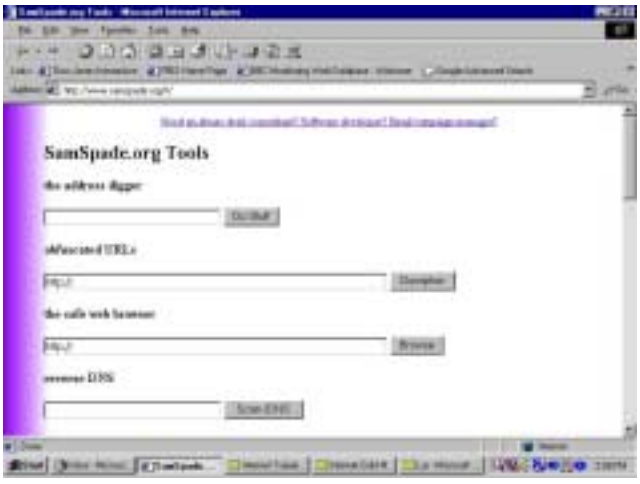

Figure 10 - Web analysis tools

- Does the web-site demonstrate a degree of influence? Do other media cite that web-site in their reporting? Has the web-site been attacked electronically or in official government statements?

- The use of free web-hosts such as Geocities.com or Cybercafe.com often suggest limited financial support for the web-site and a lack of authority in its message.

- Hit-meters/Counters that note the number of times the web-site has been visited can also provide some limited indication as to the influence of the web-site. Thought these can be misleading and should only be used as an element of an assessment of a site's authority.

Currency.

- Does the web-site provide information that is timely or are its pages dated? Some dated information can still be relevant for less dynamic topics (e.g. trade statistics) but may be misleading in tracking current events (e.g. presence of insurgent activity).

Objectivity.

- Does the web-site correspond to a known advocacy group? Does the site represent individuals or an organization? Does that site claim to speak for the organization? Is that site the main web-site or a satellite web-site that represents only a sub-element of the organization.

- To whom does the web-site link? Many sites provide a list of relevant links. These attempt to direct visitors to a community of interests that share similar interests or views. An evaluation of those links can further illuminate the views of the web-site authors.

Relevancy.

- Is the information contained on the web-site relevant to the question at hand? Many web-sites provide information related to a particular topic but do little to add to the understanding of the issue. Information provided can often be interesting but not relevant to the OSINT analyst.

WEB SITE EVALUATION CHECKLIST

Each Internet Website of potential intelligence value must be evaluated as to its suitability for intelligence exploitation *before* it is cited in OSINT reports or used as collateral information in classified reporting. The essential questions remain: who, what, where, when and why?

1. WHO? Examine the URL first. In the page scan for names, and "about" links.

What type of domain is it? (.com / .org / .edu / .gov / .mil / country code) – Is this appropriate for the material presented?
Might it be a personal page? (use of ~ in URL often suggests this)

Who wrote it? **Look for e-mail contact.**
Credentials? **Search on author's name.**
Check source code as webpage's author is often embedded in the code.

Who is the owner of the host server? **Use WHOIS and DNS LOOKUP tools at www.samspade.org to determine the registered owner of the website and evaluate this information. Does this match earlier information gathered?**

What do others say? **Search to see if others cite the author or the web-site.**
Who links to it? **In Google or AltaVista, enter the search string (*link:webaddress)* to find who links to the site. Evaluate the community of interests.**

Opinions of it? What do others think of this website?
Found in any reliable directories? **Determine if the website is contained within reliable web directories or web portals for the topic.**

2. WHAT?

Is the material presented authentic, with sources and dates?
Is data unaltered from its original source?
Note: Little value can be attached to information that is either undated or unsourced.

3. WHERE?

Where does the information originate? **Use www.samspade.org to conduct a TRACEROUTE search. TRACEROUTE will determine the path between your computer and the server hosting the information.**
Is the server located where the author purports to reside? Why or why not?

4. WHEN?

How current is the information provided? **Look for a last updated statement or dates on references.**
How often is the information maintained? Should it contain more recent information?

5. WHY?

What's the page's aim, intent?
Why was it created?
Who sponsor's the page? **Look for an "About us" entry.**

Source: Developed from material created by Joe Barker and maintained on server: www.lib.berkeley.edu.

SECTION D. SEARCHING ANONYMOUSLY ON THE WEB

Overview

While much of the OSINT cycle can be conducted openly, a robust OSINT programme should include a capability to work anonymously on the Internet. Despite the fact that all information on the web is freely available to anyone with a PC and an Internet connection, there are security dangers in searching for it.

All Internet traffic is subject to monitoring at virtually any point by elements external to your organization. It would be of little surprise that NATO was interested in insurgencies in the Balkans and Internet searches on this topic would seem natural from Alliance web addresses. Specific searches on individual leaders of insurgent groups would reveal a heightened interest and potentially reveal intentions. This sort of activity should be protected.

Being anonymous on the web may not necessarily involve deception. It is quite possible to surf the web without openly identifying your identity, purpose or intentions. This is simply a case of "I won't tell you unless you ask."

Before you even start surfing anonymously make sure you don't leave your Internet connection open to attack. You may take all the precautions necessary to hide your intentions and identity whilst surfing, but, without precautions, all the sites that you have visited and all the information you have downloaded is stored on your PC is available via your open connection, then you are vulnerable.

There is an argument for the use a firewall to stop hackers at the front door, but remember that there hasn't been a firewall yet that wasn't eventually cracked. The very expensive firewalls do a good job but it is

Elementary steps to create and maintain an anonymous WEB-Presence

Disable anything that records your activity.

If using MS Internet Explorer:

- **Turn off the cookies**
- **Clean out the history folders, and**
- **Routinely remove cached files.**

Use removable storage media to save any downloaded files to.

Only use your Internet PC for surfing. Do not use the word processor for business or personal letters.

Make sure all your connection details are anonymous.

Ensure the set up of your system is as standard as possible.

Figure 11 - Maintaining an anonymous presence

unlikely that you would want to spend so much money for a simple Internet connection. Besides if you wanted to remain anonymous on the Internet an expensive firewall is not the way to do it. It would highlight the fact that you had something to hide. The same argument applies to the cheaper firewalls. Because they are cheap they are also vulnerable. Hackers know how to get in and often see areas with firewalls as a challenge. One of the best means of security is to remain anonymous and look just like everyone else. By doing this, if a hacker chooses to attack your Internet connection whilst you are online, they would find nothing. The hacker would probably then get bored and never bother you again.

Leaving a Footprint

When you surf the Internet you cannot fail to leave a footprint. A footprint is an electronic signature that identifies you as a unique identity on the Internet during your current session. Most Internet Service Providers (ISPs) now issue a new signature to you each time you log on to surf. But whilst you are surfing during a session after log on, every site you visit retains your electronic signature. If you are trying to find information on a sensitive subject it is possible to carry out an analysis of the sites you visit and the subjects you are searching for. It would be sensible to log off and on again a number of times during a sensitive search.

Although an ISP may provide you with a new signature, part of that signature will identify the ISP. If your organization is large and has its own ISP this will identify your organization. It is always better to go through a civilian ISP whenever possible.

It is possible to use a number of different ISPs. These days there are a huge number of free ISPs available. Each country has its own list of free ISPs and details of these can be obtained via the Internet. It is possible to hide the country from which you are searching from by dialing up an ISP in another country and beginning your search from there. It is almost impossible for a hacker to identify which country your call originated from because Telecoms companies take their personal privacy obligations very seriously.

There is one thing that may identify your country of origin and that is the date and time of your search. When you surf, the date and time of your PC is stamped on the search as part of the electronic signature. If this does not match your ISP time it may indicate that you are trying to hide something, so make sure your PCs time is set to the time zone of the country of the ISP you are using.

Traffic analysis

Every web site has the capability to log the number of visitors to its site and the electronic signature of the visitor. Whilst you may be able to hide your identity, you cannot hide the fact that you have visited the site. If the number of visitors to a significant site increases dramatically then this may be an indicator that there is new or renewed interest in the subject of the site. Such a site may be set up deliberately to identify interest, for example an obscure terrorist related site.

The way to combat this is to ensure that trained personnel, in a central location do all sensitive searches. This will ensure that searches are done quickly and without repetition. The security education of all personnel who have access to the Internet is also a very important factor.

Contact with Others

There may be occasions when you may want to communicate with others to solicit information. In most cases it is beneficial to explain who you are and ask for help or information. There may be other occasions when you may not want others to know exactly who you are or whom you work for. The reasons for this must be decided on a case-by-case basis. It is reasonably easy to create an anonymous persona on the web but the following points should be noted.

It is better to employ discretion rather than deception when soliciting information on the web. This will be less publicly embarrassing later and will make an explanation of your action more reasonable.

An anonymous persona should only be used for occasional requests for information. Any development of a relationship using the Internet should be discouraged. This is the field of other specialists and without proper control can lead to embarrassment.

SECTION E. PRODUCTION

Overview

The four main elements of OSINT production are listed in Figure 12. As

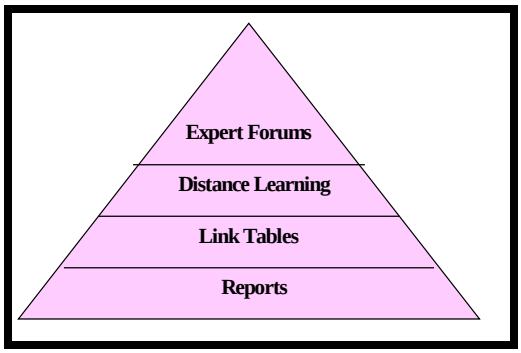

Figure 12 - OSINT Production Elements

opposed to other intelligence disciplines, OSINT relies upon outward engagement beyond the institutional confines of the intelligence staffs. Engagement is essential to the successful exploitation of open sources. This requires knowledge and understanding of information outside of intelligence channels in order to locate and exploit the best sources of information relevant to an intelligence problem and engage them in a meaningful exchange.

OSINT's four production elements will be explained within this section. While the degree of complexity will vary depending upon the intelligence requirement, those four elements will all remain applicable.

A major difference between the OSINT process and the traditional all-source intelligence process exists in how "reports" are treated. In the traditional classified intelligence process, reports are the end of the process—in the OSINT process; they are the beginning, one of four key elements in the *interactive* and *consumer-oriented* process of OSINT support.

Reports

In Chapter One, a distinction was drawn between OSIF, data that has been collated together and is of generic interest, and usually broadcast or widely disseminated and OSINT, information that has been deliberated discovered, discriminated, distilled, and disseminated to a specific consumer in order to answer a specific intelligence need.

NATO OSINT specialists will have occasion to do both kinds, but must be very clear in their own mind, when doing a report, as to whether it is an information report for general broadcast, or an intelligence report for a specific operational purpose.

A report should have an analytical summary. This is value-added expertise from a trained NATO professional who has first screened and integrated multiple elements into an underlying framework, and then devised an executive summary that can stand on its own.

Generally a Report, e.g. a report on Kosovo, will have more than one section, for instance, sections on political, military, insurgents, health, police, and external assistance. Each section should in turn have a short summary, no more than a paragraph in length. The section summaries can be used to create the overall report summary, but should be further distilled and not simply strung together.

Within each section (or linked to each section summary if done in a web-based format) should be between one and five key items of raw information—whether a transcript from a news conference, or a wire service release, or a commercial image, or an extract from a foreign military map.

A major difference between OSINT and other clandestine or covert sources is that OSINT strives to provide concurrently both analytical value and direct access to raw materials. OSINT sources rarely require protection. Text-based products can be stored and disseminated easily by electronic means.

By providing the consumer (the commander, the operator, the logistician, or the all-source intelligence analyst) with direct convenient access to the best of the raw materials, the OSINT analyst is enabling the consumer to dig deeper if they chose to while satisfying the initial RFI.

Reports should always show, on the first page, the date and hour at which collection (not production) was cut off, and the time period in days and/or hours that the report covers. Reports can be organized by source (Internet, Commercial Online, Grey Literature, and Experts) or by topic. They should always identify the author and if appropriate the reviewer of the Report, and provide complete contact information so that readers may quickly ask follow-up questions of the originator.

COUNTRY (e.g. Sri Lanka)

TOPIC (e.g. Economy)

Link Tables

Internet search engines, even recommended meta-search engines, have severe limitations. By some accounts, any one search engine will cover only 10-15% of the visible web, and even all the search engines working together will overlook what is known as the "deep web." The deep web consists of complex sites with many levels, many free and some by subscription, where search engines are simply ineffective. While some tools such as the affordable software programme *Lexibot* are available to assist in collection from the "deep web", considerable time is spent in the identification and analysis of open sources relevant to the information requirement. For this reason, a major aspect of the OSINT support process is the skilled creation of Internet Link Tables that serve as a ready reference for the commander or staff officer who desires to rapidly scan external information sources without necessarily requesting a report. This browsing endeavor can often help the commander or staff principal reflect on their requirements and better articulate their next demands for finished OSINT. An Internet Link Table should generally be in the form of a Table, such as is illustrated In Table 5 above. By using the Word Table feature, this allows the sorting of the information based on either the Rank or Weight assigned to the site, the URL or title of the site, or the description category of the site. Over time, as various NATO components cooperate and share Link Tables with other allies forces such as the various regional Joint Intelligence Centers, a very comprehensive directory of web resources, one that is tailored to NATO's needs, should emerge.

Ranking	Link	Source
10	http://allafrica.com/libya/	**All Africa News – Libya –** Up-to-date news on Libya, in English and in French.
10	http://memory.loc.gov/frd/cs/lytoc.html	**Library of Congress Libya Country Study** – Excellent, in-depth country study
10	http://members.aol.com/LibyaPage/	**Libya Resources on the Internet –** Excellent, comprehensive site, includes news, Qadhafi info, maps and satellite photos, military and intel, etc.
10	http://www.un.int/libya/	**The Permanent Mission of Libya to the UN** Website **–** Includes press releases & statements, ambassador's remarks and links.
10	http://www.nfsl-libya.com/	**The National Front for the Salvation of Libya** - The NFSL is an opposition movement against the dictatorial regime of Qadhafi in Libya, and was formed in October 1981.
8	http://www.libyamazigh.org/	**Libyan Amazigh** site. Contains info on Libya's Amazigh (Berber) culture, language and history.
8	http://www.libyaonline.com/index.html	**Libya Online** Website – Contains basic facts about Libya, tourism, business, arts, literature and sports.

Table 5 - Example of Internet Link Table

Distance Learning

The Internet, while rendering a major service to those who would like to share information efficiently and also interact inexpensively with diverse people all over the world, has also reduced the productivity of even experienced personnel. Constant interruptions and distractions through diversions to less important information are

core factors. For this reason, there is an urgent need for Distance Learning modules on all countries and topics that are of interest to NATO. The objective is to ensure that all new personnel, and especially new action officers, have an online resource that can serve as a sophisticated turnover file and reference point. This is also a place where unclassified biographic information can be made available, and where annual reviews of each country or topic can be placed.

The U.S. Pacific command initiative known as the Virtual Information Center is an good example of this process. It can be accessed at www.vic-info.org.

Figure 14 - Homepage of US PACOM OSINT Centre

Expert Forums

A number of software programs exist with which to manage a variety of Expert Forums, including private teams with their own newsletters, calendars, and automated email alerts whenever new information is posted. One of the most popular is the Alta Vista Forum. One of the newest, with powerful security features, is offered by Groove Inc. (www.groove.net) and represents the emerging shift in communications and computing power away from centralized server farms toward what is known as "peer to peer" edge units.

Expert Forums can be internal, external, or some combination of the two. Once experts have been identified, they may be invited to join the Expert Forum sponsored by any NATO element. This should be done with the understanding that they will contribute their time and insights on an occasional basis, in return for being granted access to the OSINT being produced by the NATO element sponsoring the Expert Forum. Such a forum can also be a place where individual experts "audition" for short-term consulting contracts and where the biographies of available efforts can be made available for anonymous review by potential NATO employers.

Expert Forums should consist of several parts, all of them of potentially great value to the NATO OSINT process. First, while it is possible to register anonymously for a forum, the greatest value comes from an open registration that includes a photo, biographic note, and complete contact information. Second, the forum will quickly self-organize, with a variety of topics to which an individual can not only contribute observations, but to which they can upload documents, images, even video. The flexibility and scalability of these forums cannot be overstated—but they do have one major flaw: at this time, it is not possible to apply visualization or other technologies to the varied contents of a forum—each item must be copied down to a master database first.

Soon the technology will be available to index and abstract all information contributed to a forum, at which time the best of all worlds will be available: distributed experts able to cast a wide net, and a centralized "banking" function for information freely contributed by various parties. Third, the forum permits the rapid organization of private working groups, and offers calendar, newsletter, and other

coordination features. Fourth and last, the forums can provide an automatic email alert to any member whenever new information is posted to a topic of interest to them, relieving them of the need to constantly check the forum site.

SECTION F. DISSEMINATION AND EVALUATION

Overview

The major difference between OSINT and the other intelligence disciplines is that the latter are inherently classified: OSINT can be shared with *anybody* that the commander deems appropriate, without having to request security or political clearances.

This makes it extraordinarily valuable in non-article V operations as well as in dealing with civil sector coalition partners—including NGO that traditionally distrust the military in general and intelligence professionals in particular. OSINT has become even more valuable in the 21st Century, as there has been a major change in the over-all C^4I paradigm.

As NATO continues to evolve and transform itself in response to the many new challenges, the importance of OSINT will continue to evolve. These new challenges include non-traditional non-military challenges requiring coordinated action with non-governmental and humanitarian relief organizations.

OSINT appears to offer a very substantial advantage as a prime intelligence source and method with which to achieve consensus and a common understanding of the shared area of operations.

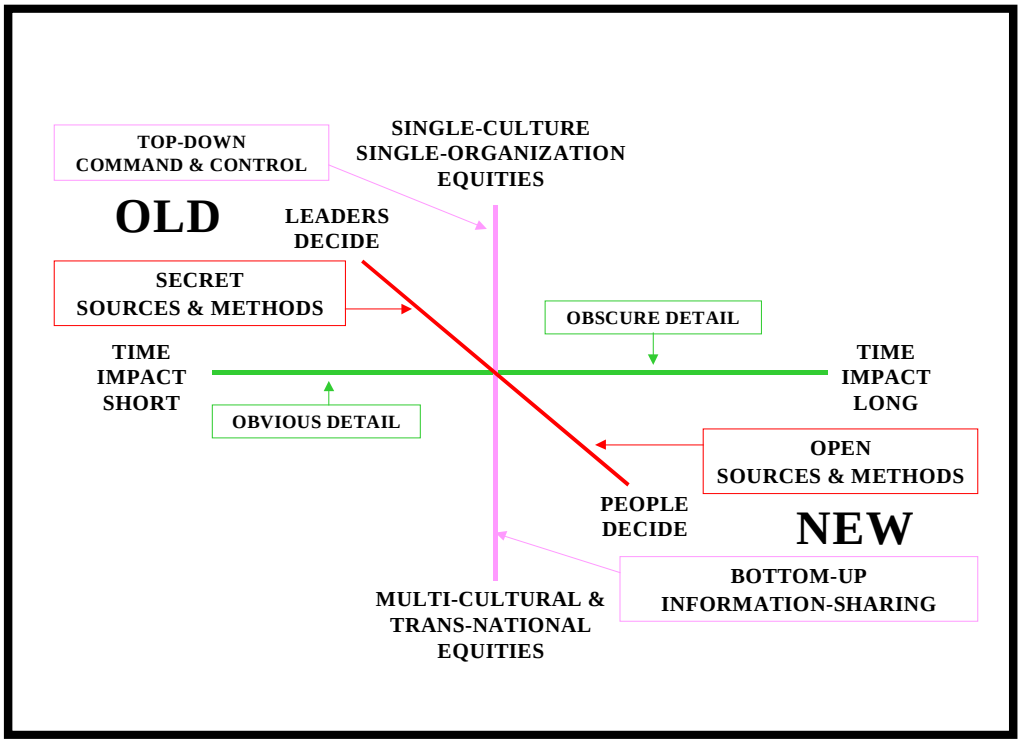

Figure 15 - Emerging Paradigm for Information Sharing

Dissemination Methods

Once open source information has been developed into OSINT, it can be disseminated via the NATO WAN in a "push" mode, or it can be "pulled" off on demand.

The limitations placed on its dissemination are based on the security policies of the organization producing it. While some OSINT products may be shared openly, others may provide details of interests or intentions and should therefore be restricted in their dissemination. The dissemination policy should be driven by the mission requirements. The approach should nonetheless be flexible to fully leverage the ability that the production of OSINT products provides for the engagement of non-NATO elements in security discussions or the development and dissemination of a common view of the operating area.

Within the NATO Intelligence Architecture, options exist for the dissemination of OSINT products via the classified NATO WAN or directly through the Internet. The advantages of the NATO WAN are the direct access afforded to the operations and policy staffs at all levels, including deployed units, as well as the security afforded by the use of a classified system. The principal disadvantage of the NATO WAN for OSINT dissemination is the necessary separation of the products from their source material. Without a direct linkage between an OSINT product and the sources of information, the recipient is less able to drill deeper for additional information, reach the original author, or further evaluate the original sources of the information.

Another option is the use of a Virtual Private Network (VPN). A VPN is a restricted community of interest that communicates on the Internet but use security safeguards to limit the access from others who are not members. By using a VPN, OSINT products can be accessed safely and with working links directly to the original source material. Link tables can also be maintained that enables the rapid collection of information. Other OSINT centres within NATO member countries have direct access to the Internet; few have access to the NATO WAN. A VPN provides the means with which to exchange OSINT products with other OSINT centres across NATO. Finally, the use of a VPN provides the means with which to disseminate OSINT products with non-NATO elements such as NGOs and other international organizations as mission requirements demand.

For these reasons, exploring the feasibility and desirability of a VPN to support the NATO OSINT Initiative remains a priority. SACLANT has begun a trial VPN with the U.S. Open Source Information System (OSIS) to examine the viability of linking NATO OSINT production centres with U.S. OSINT holdings.

Virtual Intelligence Community

The NATO OSINT initiative is the first major multi-national OSINT initiative ever undertaken. While there is much still to learn from those member nations that adopted OSINT as an independent discipline in the 1990's, as well as from the emerging business intelligence community (such as represented by the Society of Competitive Intelligence Professionals at www.scip.org), it is NATO that is leading in the establishment of formal doctrine and tables of organization and equipment specifically earmarked for OSINT. It is helpful, in contemplating this activity, to understand that there is a substantial but still fragmented community of interests with whom NATO could co-develop many OSINT initiatives. This community is illustrated in Figure 16.

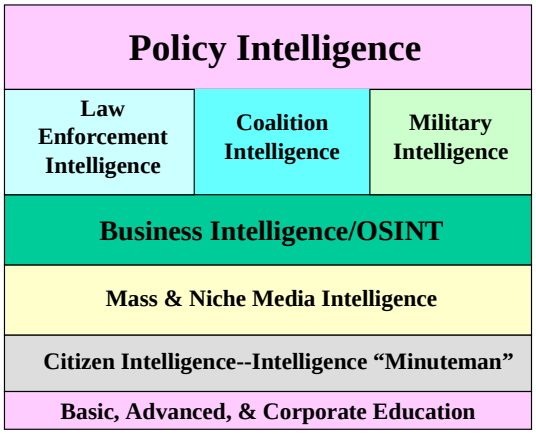

Figure 16 - Elements of a virtual intelligence community

As commanders and their staff evaluate their needs for OSINT, and new methods as well as budget deficiencies, SCs and subordinate commands should seek to establish a constant process of interactive liaison with each of the elements of the "virtual intelligence community" shown here. In this fashion, NATO intelligence could benefit from a greater OSINT effort that cuts across bureaucratic and cultural boundaries, and leads to improved cost efficiencies and new forms of information sharing.

CHAPTER IV
OSINT AND THE EMERGING FUTURE INTELLIGENCE ARCHITECTURE OF NATO

SECTION A. BLENDING OSINT INTO THE ALL-SOURCE PROCESS

Overview

Apart from the importance of OSINT as a means of establishing consensus and a common view with external parties about the shared area of operations, OSINT is absolutely vital to the all-source intelligence process. OSINT provides the historical background information, the current political, economic, social, demographic, technical, natural, and geographic context for operations, critical personality information, and access to a wide variety of tactically useful information about infrastructure, terrain, and indigenous matters. The relationship between OSINT, the traditional collection disciplines, and all-source analysis is shown in Figure 17.

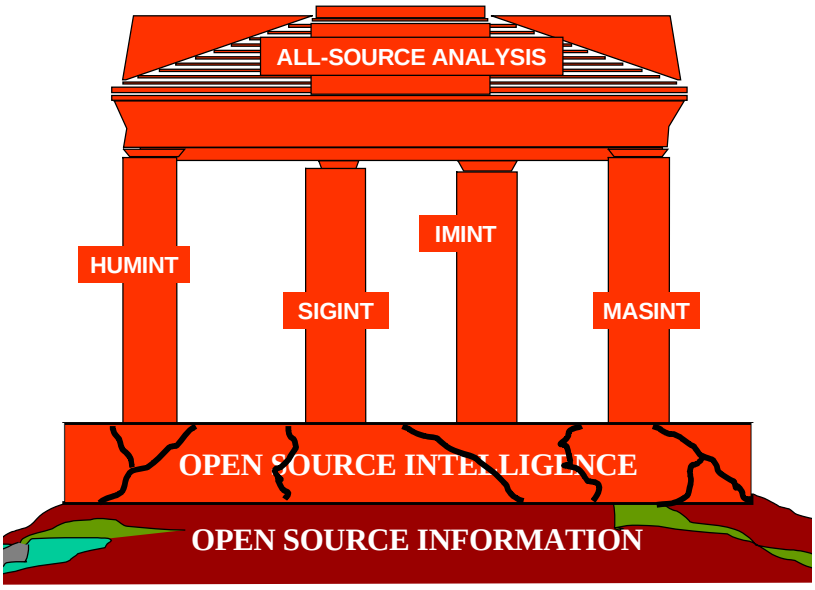

Figure 17 - Open Source - All-Source relationship

Cracks are shown in the OSINT foundation to emphasize that this vital element of the all-source intelligence process has been too long neglected. Following the publication of the Alliance's Strategic Concept in April 1999, OSINT is even more important. NATO, along with other international organizations, is now striving to understand ethnic conflict, water and food scarcity, mass migrations, the collapse of public health across entire continents, transnational crime, and all of the small wars—and the potential threat of large wars—that remain a traditional responsibility. OSINT can and should be integrated into every aspect of the all-source process, from collection through production.

Nations and NATO commands differ fundamentally in their approaches towards OSINT. Both begin with intelligence needs that lead to the generation of intelligence requirements. The approaches diverge at that point. While nations may use OSINT to guide classified collection, NATO rarely has classified collection means beyond the tactical level and those assets are largely restricted to theatres in which forces are already deployed.

NATO commands can use OSINT-V to satisfy intelligence gaps for a large number of its intelligence needs. While nations are able to turn to classified intelligence collection, NATO can and should use the OSINT process described as the first step in its collection process. Too often, NATO commands have defaulted to sending RFIs to nations rather than seeking first to address their intelligence requirements themselves. The range of open sources now within reach of NATO intelligence staffs provides other options.

The new Strategic Concept articulated a vision for the Alliance that is largely focused on non-traditional operating areas and transnational threats. The intelligence services of the NATO member countries are also struggling to deal with a similar problem set. These areas and interests, while not well covered by traditional intelligence production are well addressed in open sources. Rather than relying solely upon nations for intelligence products, NATO intelligence staffs should develop their own network of open sources as the starting point for the compilation of their intelligence assessments.

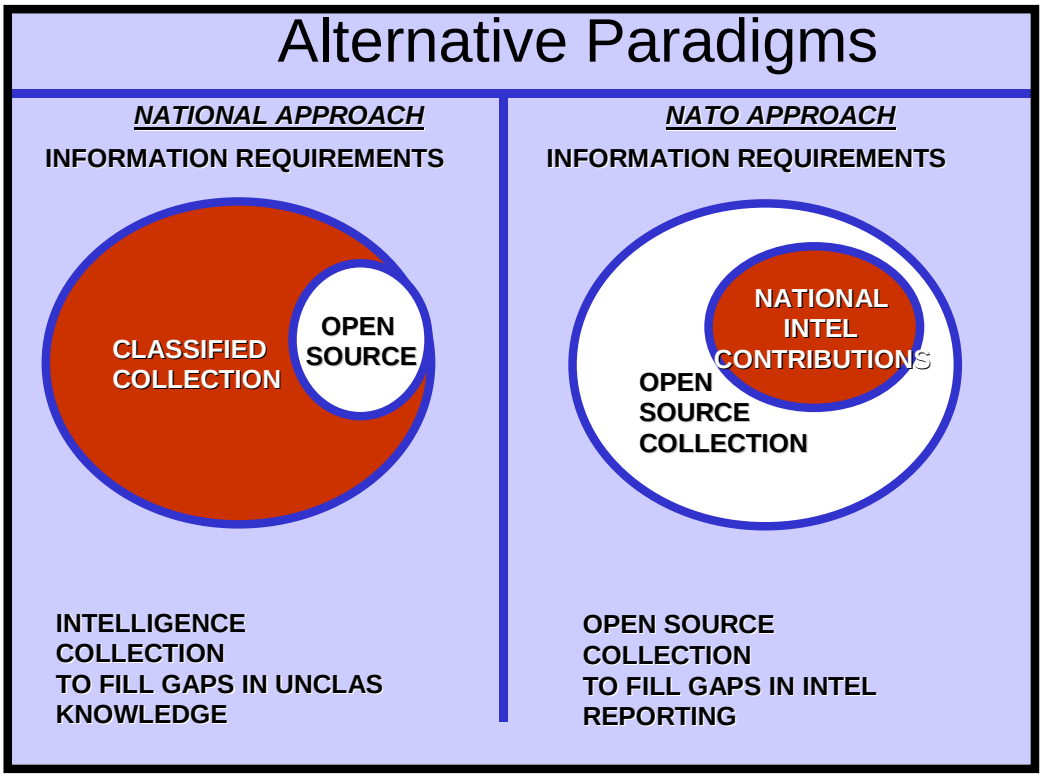

Figure 18 - Alternative Paradigms between NATO and National OSINT Approaches

Direction

Open information sources are as easy for NATO leadership to access as they are for their intelligence staffs. No longer are intelligence staffs in a position to regulate the flow of relevant information to the commander or his staff. Virtually all decision-makers make regular use of open sources to varying degrees. Knowledge of those sources routinely consulted by the staff principals is an important means with which to stay ahead of their intelligence needs.

Rather than attempting to stem the use of open sources by the commander or his staff, an effective OSINT effort facilitates it. Intelligence staffs at both Strategic Commands (SCs) have access to specialized information retrieval tools and commercial sources. In addition, both SCs are in a position to provide training and advice on the effective retrieval of information from open sources. An OSINT process should include the provision of validated information sources for each issue that affects the command. The provision of Link Tables as well as quality assessments of other information sources is an essential OSINT product.

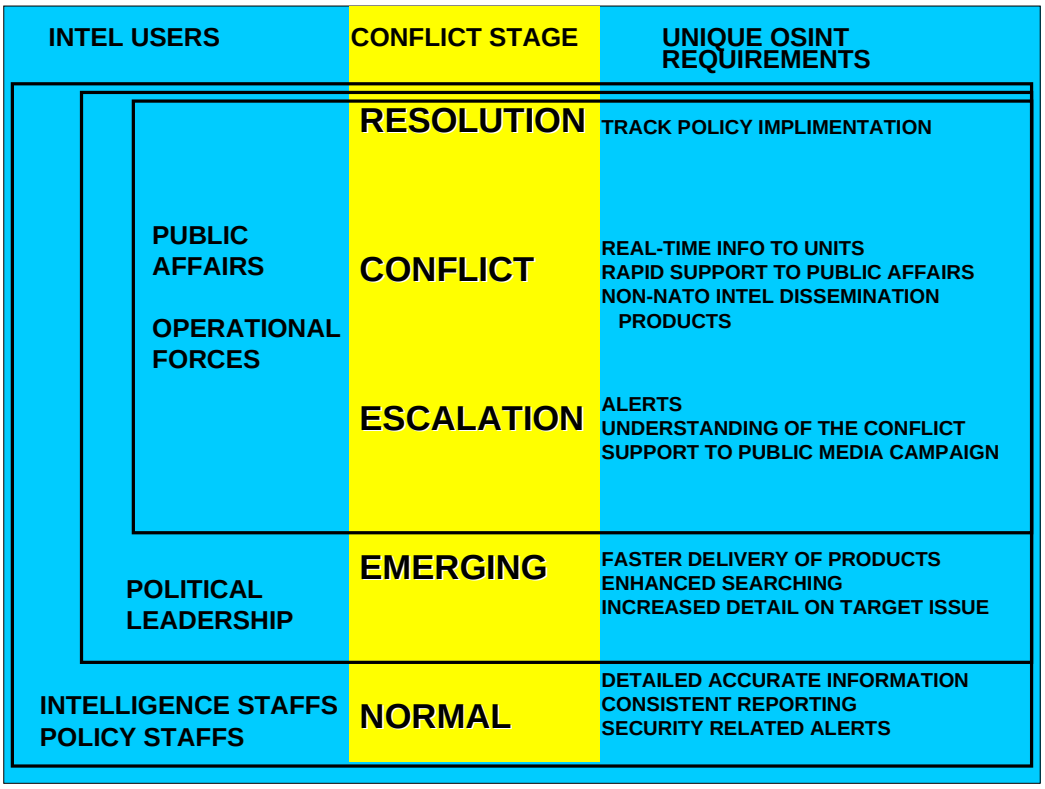

Figure 19 – Unique OSINT Requirements across the Conflict Spectrum

Typically, informed decision-makers make reasoned requests for intelligence. While not always the case, this statement generally holds true. With an appreciation for what is widely known, intelligence users will tend to restrict their requests to that information which they do not already have available to them.

OSINT can support the direction phase of an

all-source intelligence effort through discovery of an issue or providing context with which to understand issues.

The intelligence problem varies depending on the nature of the issue being addressed, which elements of the staff are engaged and what degree of information is required. Figure 19 shows a representative range of information products that a robust OSINT capability can provide.

Assuming an OSINT capability is in place in advance of a crisis, it is likely that the leadership will have had access to quality open source products prior to the onset of mission requirements. In that case informed RFIs can be expected. If there is no familiarity with the issue, decision-makers can be directed to either established OSINT products or open sources of information that can be made available through access to an information portal such as a VPN of another network. Finally, an OSINT collection effort can be initiated to quickly produce relevant background information. This immediate OSINT effort will quickly establish what is easily known about the subject and guide the priorities for classified collection and all-source production.

Collection

Within the intelligence cycle, the collection phase includes the translation of the intelligence need into a collection requirement, the definition of a collection strategy, the selection of the collection sources and the actual information collection. Open sources should be the first recourse in the collection process. OSINT saves money in reducing unnecessary classified collection. In a NATO context, it saves time as RFIs to nations require sufficient lead-time for them to be properly addressed.

While open source information is not free, the costs pale in comparison to those of the classified collection disciplines. If open sources can be collected to produce an OSINT product that addresses completely or to a large degree the intelligence need, classified collection resources can be more effectively deployed elsewhere.

While nations have classified collection capabilities, these are expensive and must always be used wisely. NATO has no tasking authority over national intelligence collection capabilities. Its reliance upon intelligence contributions from nations makes it incumbent upon its intelligence staffs to know what can be known without technical collection.

Open sources have always been used by intelligence organizations. Open sources have typically been referred to as *collateral reporting*. In fact, all single source intelligence disciplines refer to information provided by another intelligence discipline as *collateral reporting*.

However, when this collateral reporting is maintained with a systematic disciplined approach as discussed in this OSINT Manual, the “collateral” grows in its own utility. Instead of being acquired once and used by one intelligence element, it is acquired once and applied across a broader range of the intelligence process from streamlining collection to increasing dissemination.

OSINT’s four main contributions to classified collection are: tip-off for classified sources; targeting of those sources; context and validation to better understand material collected from classified sources, and; providing plausible cover to protect the classified source.

Tip-off.

- Open sources are particularly well suited to providing *tippers* for other collection disciplines. The reduction in the number of denied areas since the end of the Cold War and the advent of cheap international transportation options have enabled greater media access than ever before. Internet NEWSGROUPS, wire services and other traditional print and broadcast media are all within the reach of anyone.

- The Internet remains a primary means with which to gain access to these sources. While traditional print and broadcast media are restricted in the amount of information that they can provide, the Internet has provided virtually limitless dissemination capabilities for information producers. Rather than the editor's selection of stories, the Internet provides the means with which to gain access to all stories filed with all of the wire services depending on the degree of access that is purchased.

- A number of services provide news alerts that are either free of charge or low cost. Non-traditional sources of information include those who witness important events and who post messages on the Internet about what they have seen. While prone to disinformation, this is another source of information that must be evaluated like all others. Those who witness an event and publish on-line or forward emails to their communities of interest can provide the first indication of an event even before media publication.

Targeting.

- While OSINT will often be able to address elements of an intelligence problem quickly and efficiently, OSINT will never invalidate the need for classified collection capabilities.

- When intelligence gaps can be addressed without the need to task classified collection sources overall demand upon limited collection resources decreases. This permits concentration of effort on those issues that can only be discovered through classified collection.

- This model of complementary collection permits both open and classified sources to be optimized for a particular intelligence problem, while at the same time, affording the all-source analyst the ability to use the classified collection products to validate the OSINT products.

Context/Validation.

- Supplemental open source reporting can provide the means with which to place classified reporting into context. Classified reporting, particularly current intelligence reporting, often fails to provide the necessary background information with which to tailor the information to the needs of the recipient or to explain the nuances of the situation.

- While imagery can provide knowledge of ships alongside piers, additional information from open sources can provide an understanding of the cargo that the port handles or the schedule of the ship. Similarly, UN reporting on agriculture production shortfalls in a particular country will give insight into population movements detected with national technical means.

Plausible Cover.

- OSINT is particularly useful in protecting classified sources and methods. The discovery of an open source that corroborates classified

Figure 20 - Commercial imagery of San Diego naval base

reporting may increase the releasability of the initial information by providing a plausible alternate source. This also has applicability to the staffing of requests for the sanitation of classified reporting.

- A thorough understanding of information that is available in unclassified channels facilitates the discovery of plausible alternate sources to classified intelligence reporting. This ultimately increases the ability of intelligence staffs to release intelligence information to non-NATO elements within missions.

Processing

The objective of intelligence processing is the creation of an intelligence product that is value-added, actionable information tailored to a specific user. All-source analysis with its fusion of all relevant and validated sources of information remains the best means to convey intelligence to the user. This process includes both classified and OSINT reporting as appropriate. In most cases, NATO will serve as one element of an international crisis response. Experience has shown that these operations likely include the leading of a broader coalition alongside non-NATO troop contributing nations (NNTCNS). The processing of intelligence products to support the information needs of both the NATO-led force and the international response elements is greatly enhanced with a robust OSINT capability.

Intelligence products can be prepared with a tear-line – classified intelligence restricted in its dissemination above the line and sanitized information that can be more broadly disseminated below the line.

OSINT–V products can be produced specifically tailored for the broader coalition audience but validated by the all-source process. During actual operations, the need to disseminate to non-NATO elements includes not only their operational forces, but also their political liaison elements at NATO headquarters in Brussels.

Figure 21 - Nature of international operations

The maintenance of information sources that can be disseminated outside of NATO channels can often prove essential to both establishing a common view of the operating area and initiating an exchange with other entities that can contribute to the understanding of an issue.

Dissemination

As stated earlier, OSINT is itself optimized for dissemination through VPNs. This enables ready access to the original source material, direct interaction with other related open sources and access to other OSINT producers.

The dissemination of OSINT products as stand-alone intelligence products on classified systems should also be encouraged. OSINT as either stand alone products or as collateral reporting adds to the body of knowledge on a particular issue. Intelligence staffs at all levels should be able to benefit from the effort put into their production. It is rare that all subordinate commands will have access to every intelligence system. Thus, efforts should be made to ensure that products are available on all intelligence dissemination systems as security constraints permit.

Typically, the lower the classification of an intelligence product the wider is its uses. If decision-makers are able to leave their offices with an intelligence product, it is more likely that it will receive undisturbed attention. OSINT products provide the means to place high quality low-classification or unclassified products in the hands of intelligence users. This is only possible if they are disseminated on systems typically used to deliver other forms of intelligence.

The objectives of a robust OSINT capability should be to increase the range of information available to intelligence users and to facilitate interaction with non-NATO elements as appropriate. The dissemination options developed should seek to achieve these two objectives.

APPENDIX C: CATEGORIES OF MISPERCEPTION AND BIAS

Evoked-Set Reasoning: That information and concern, which dominates one's thinking based on prior experience. One tends to uncritically relate new information to past or current dominant concerns.

Prematurely Formed Views: These spring from a desire for simplicity and stability, and lead to premature closure in the consideration of a problem.

Presumption that Support for One Hypothesis Disconfirms Others: Evidence that is consistent with one's preexisting beliefs is allowed to disconfirm other views. Rapid closure in the consideration of an issue is a problem.

Inappropriate Analogies: Perception that an event is analogous to past events based on inadequate consideration of concepts or facts or irrelevant criteria. Bias of "Representativeness".

Superficial Lessons From History: Uncritical analysis of concepts or event, superficial causality, over-generalization of obvious factors, inappropriate extrapolation from past success or failure.

Presumption of Unitary Action by Organizations: Perception that behavior of others is more planned, centralized, and coordinated than it really is. Dismisses accident and chaos. Ignores misperceptions of others. Fundamental attribution error possibly caused by cultural bias.

Organizational parochialism: Selective focus or rigid adherence to prior judgments based on organizational norms or loyalties. Can result from functional specialization. Groupthink or stereotypical thinking.

Excessive Secrecy (Compartmentation): Over-narrow reliance on selected evidence. Based on concern for operational security. Narrows consideration of alternative views. Can result from or caused organizational parochialism.

Lack of Empathy: Undeveloped capacity to understand others' perception of their world, their conception of their role in that world, and their definition of their interests. Difference in cognitive contexts.

Mirror-Imaging: Perceiving others as one perceives oneself. Basis is ethnocentrism. Facilitated by closed systems and parochialism.

Ignorance: Lack of knowledge. Can result from prior-limited priorities or lack of curiosity, perhaps based on ethnocentrism, parochialism, and denial of reality, rational-actor hypothesis (see next entry).

Rational-Actor Hypothesis: Assumption that others will act in a "rational" manner based on one's own rational reference. Results from ethnocentrism, mirror imaging, or ignorance.

Denial of Rationality: Attribution of irrationality to others who are perceived to act outside the bounds of one's own standards of behavior or decision making. Opposite of rational-actor hypothesis. Can result from ignorance, mirror imaging, parochialism, or ethnocentrism.

Proportionality Bias: Expectation that the adversary will expend efforts proportionate to the ends he seeks. Interference about the intentions of others from costs and consequences of actions they initiate.

Willful Disregard of New Evidence: Rejection of information that conflicts with already-held beliefs. Results from prior commitments, and/or excessive pursuit of consistency.

Image and Self-Image: Perception of what has been, is, will be, or should be (image as subset of belief system). Both inward-directed (self-image) and outward-directed (image). Both often influenced by self-absorption and ethnocentrism.

Defensive Avoidance: Refusal to perceive and understand extremely threatening stimuli. Need to avoid painful choices. Leads to wishful thinking.

Overconfidence in Subjective Estimates: Optimistic bias in assessment. Can result from premature or rapid closure of consideration, or ignorance.

Wishful Thinking (Pollyanna Complex): Hyper-credulity. Excessive optimism born of smugness and overconfidence.

Best-Case Analysis: Optimistic assessment based on cognitive predisposition and general beliefs of how others are likely to behave, or in support of personal or organizational interests or policy preferences.

Conservatism in Probability Estimation: In a desire to avoid risk, tendency to avoid estimating extremely high or extremely low probabilities. Routine thinking. Inclination to judge new phenomena in light of past experience, to miss essentially novel situational elements, or failure to reexamine established tenets. Tendency to seek confirmation of prior held beliefs.

Worst-Case Analysis (Cassandra Complex): Excessive skepticism. Reflects pessimism and extreme caution, based on predilection (cognitive predisposition), adverse past experience, or on support of personal or organizational interest or policy preferences.

FEEDBACK

This manual is intended to be a living document. It represents the first attempt by NATO to place OSINT within the broader context of intelligence efforts. The intention is to subject this publication to regular review and updating to reflect new sources and methods for open source exploitation.

As such, feedback is welcome in any form. Comments, amendments, additions or errors can be reported either with the form below or via email to rsc@saclant.nato.int.

Open Source Intelligence: Professional Handbook

FORWARD

1. **PURPOSE.** *Open Source Intelligence: Professional Handbook*, is published to ensure the dissemination of useful information which is vital to successful intelligence support to the military commander, and highly pertinent to law enforcement and economic intelligence operations, but which may not yet be doctrinally available.

2. **SCOPE.** This publication constitutes material that was producted under contract to the Defense Intelligence Agency, Joint Military Intelligence Training Center, by OPEN SOURCE SOLUTIONS, Inc., using copyrighted OSS Inc. materials. The material has been edited by OSS to develop a single integrated publication which can be used as both a primer and an operational guide to acquiring and exploiting open source information as part of the all-source intelligence process. Open source information is often described as the "source of first resort," and may be the *only* source available to the commander and staff when initially considering an expeditionary contingency. The information contained herein does not necessarily reflect the views, nor should any endorsement or approval be implied by the Department of Defense or the Defense Intelligence Agency, or any other government organization or authority.

3. **COPYRIGHT AND DISSEMINATION.** This publication may be reproduced without restriction by any agency of the US government. It may not be used by others without prior permission of the copyright holder, OPEN SOURCE SOLUTIONS, Inc., 11005 Langton Arms Ct, Oakton VA 22124.

INTRODUCTION

This handbook is based almost entirely on six of the eight lessons comprising the Open Source Training Course funded by the Defense Intelligence Agency (DIA). It has been prepared by the staff of the Navy-Marine Corps Intelligence Center as a means for consolidating the course materials in a form which could be most useful to the Marine Air Ground Task Force (MAGTF). All Marines will benefit from this DIA-funded initiative, which is the first organized course of instruction on open source intelligence available in the entire U.S. Intelligence Community. This material is provided to the Fleet Marine Force as an interim measure, pending the availability, possibly in 1997 or 1998, or more formal training materials from the(U.S. Intelligence) Community Open Source Program Office.

Chapter 1, OVERVIEW OF OPEN SOURCES & SERVICES, presents a broad overview of open sources and services which are important to the all-source intelligence analyst. Included in this chapter is a definition of open source and a distinction between data, information, and intelligence; a brief discussion of the history of open source intelligence as a sub-discipline within the all-source intelligence process; a review of why open sources are important to military intelligence; examples of open sources and services which are not now commonly integrated into all-source analysis; and a discussion of open source exploitation within DIA (Defense Intelligence Agency) and in a number of allied intelligence communities. This chapter concludes with a discussion of the changing role of the analyst; and how each analyst can take specific steps to improve their personal exploitation of open sources in support of the all-source intelligence process.

Chapter 2, ACCESS: INTELLIGENCE IN THE AGE OF INFORMATION, presents a more in-depth look at why open sources are critical to the all-source analysis endeavor, and how all-source analysts can optimize their exploitation of open source information. Included in this overview is a review of definitions distinguishing between data, information, and intelligence; discussions of how the art of intelligence is changing in the face of the "information explosion", the four kinds of information categories that an all-source analysts can consider accessing, and the three elements of information value; a discussion of the nine levels of open source information; an examination of possible collection management strategies which integrate open sources into the all-source collection management task and exploit windows of opportunity in which material is available in open sources just prior to being classified or censored; discussion of the four major consumer groups and their intelligence productions needs in relation to open sources; an examination of the four "warrior classes" and how open sources apply to intelligence analysis of each; discussion of the four types of overt human sources the analyst will encounter; an examination of how open source intelligence (OSINT) can help conserve scarce classified resources, and how a national information strategy can increase the amount of open source information available to the defense intelligence community; and concluding comments on optimizing OSINT in the all-source analysis process.

Chapter 3, INTERNATIONAL OPEN SOURCES AND SERVICES, provides an orientation to international open sources and services which are available to the all-source analyst. Although much of the open source world is not yet easily accessible to analysts because of security and procurement constraints, the Commission on Intelligence report of 1 March 1996 has defined such access as "critical", and recommended that dramatically improved analyst access to open sources be a top priority for the Director of Central Intelligence and a top priority for funding. This orientation discusses electronic access, the identification and acquisition of "grey literature", the identification and exploitation of international experts, and several examples of world-class international open source capabilities including Jane's Information Group and SPOT Image Corporation.

Chapter 4, THE INTERNET AS A TOOL FOR ALL-SOURCE ANALYSIS, presents a very broad overview of the global capability known as "The Internet" or "the Net". The Internet is a global communications medium that permits extraordinary flexibility in communicating with a wide variety of people from all walks of life, in receiving free information from many sources (some of dubious authenticity), and in obtaining access to distributed databases, many multi-media in nature, all over the world. This chapter will discuss in general terms the utility of the Internet to the all-source analyst, with special attention to the use of electronic mail, newsgroups, lists, and conferencing systems. It also discusses some of the dangers of the Internet, including the problems of "noise" and "flame wars", as well as the almost total lack of privacy and discretion. The last half of the chapter will focus on the most productive element of the Internet, the World Wide Web, and will provide five practical examples of how to exploit the Internet in support of the all-source analysis endeavor.

Chapter 5, OPEN SOURCES AND MILITARY CAPABILITIES, focuses on the practical application of open sources to military intelligence analysis requirements. The chapter begins by introducing a model for integrated all-source analysis which illustrates the critical importance of geographic and civil factors in evaluating the threat at each of the levels of analysis. While open sources are useful in conducting research and developing intelligence estimates about military capabilities in isolation, open sources are most useful to the military intelligence analyst when used to develop a broader analytical model. The general utility of open sources for military intelligence analysis, and the specific utility of open sources at the strategic, operational, tactical, and technical levels of analysis will be discussed. Next the chapter examines specific private sector capabilities for collecting and processing open source information. Commercial imagery, private sector order of battle information, and networks of experts available for consultation will be reviewed in general terms. Finally this chapter introduces the student to the Expeditionary Factors study developed by the Marine Corps Intelligence Activity, and used for this handbook because it is the only current and authoritative intelligence analysis product which relies exclusively on open sources, is unclassified in its final form, and covers a broad range of mission area factors for eighty countries specifically chosen because of the likelihood that a Marine Air Ground Task Force will be engaged in non-combatant or combatant missions in the countries

Chapter 6, OPEN SOURCES AND OPERATIONAL SECURITY--THE DARK SIDE, documents the premise that everything needed for the planning and execution of criminal or terrorist activity can be found in open sources. Indeed, an entire industry exists which is devoted to the publication of such material. In addition, equipment designed for one purpose and legally available can be used in terrorist or criminal activity. From both a military and a law enforcement point of view, it is critical to understand that even our most poorly-funded and least organized opponents can gain access to relatively sophisticated intelligence collection tools as well as tools of destruction.

Chapter 7, CONCLUSION: COLLECTING AND PROCESSING OPEN SOURCE, wraps up the handbook by providing information about three official U.S. government channels for obtaining open source intelligence: the Community Open Source Program Office and its global Open Source Information System; the Defense Intelligence Agency Open Source Program and the (planned) Defense Intelligence Agency Open Source Intelligence Center; and--especially important for Marines--the Marine Corps Intelligence Activity and the Expeditionary Factors Study. The Chapter concludes with a brief discussion of the usefulness of the Marine Corps Reserve as a source of existing and new open source exploitation experts, and some recommendations on additional open source training opportunities.

The APPENDICES provide both additional background information, and explicit references and points of contact which can be used to acquire open source intelligence in support of the commander and the staff. Appendix A, a White Paper on "Open Source Intelligence: What Is It? Why Is It Important to the Military?" was commissioned by the French Ministry of Defense and used (in translation) to begin the process of creating a French open source intelligence capability. Appendix B, consisting of both talking points and a formal paper on "Private Enterprise Intelligence: Its Potential Contribution to National Security" was developed as an invited paper for the annual open conference on Canadian intelligence. Included in Appendix B are a number of direct points of contact and key references useful in starting an open source intelligence program. Appendix C, a White Paper on "ACCESS: Theory and Practice of Intelligence in the Age of Information", was also commissioned by the French, and represents a somewhat abstract but still useful discussion of open source intelligence as a supporting discipline. Appendix D is a Concise Directory of Selected International Open Sources & Services which was prepared for the Defense Intelligence Agency, and remains both current and useful. Appendix E is a series of papers prepared for the Defense Intelligence Agency and serving as primers on exploiting the Internet, with over 100 pertinent intelligence-oriented sites and lists being identified in detail. Appendix F is a combination of a model (the original Expeditionary Environment Research & Analysis Framework & Model 1990) and strategic generalizations from the first Marine Corps Intelligence Activity study, *Overview of Planning and Programming Factors for Expeditionary Operations in the Third World*. Appendix G provides key references documenting what is available to terrorists and criminals which should be of concern to the military professional from an operations security viewpoint. Finally, Appendix H provides a list of the 80 countries examined in the current MCIA study, *Expeditionary Force Mission Factor Intelligence Analysis Requirements Study* dated 15 September 1994.

Chapter 1

OVERVIEW OF OPEN SOURCES & SERVICES

1001. Purpose of the Chapter

The purpose of this chapter is to present a broad overview of open sources and services which are important to the all-source intelligence analyst.

Included in this chapter will be a definition of open source and a distinction between data, information, and intelligence; a brief discussion of the history of open source intelligence as a sub-discipline of the all-source intelligence process; a review of why open sources are important to military intelligence; examples of open sources and services which are not now commonly integrated into all-source analysis; and a discussion of open source exploitation within DIA (Defense Intelligence Agency) and in a number of allied intelligence communities.

This chapter concludes with a discussion of the changing role of the analyst; and how each analyst can take specific steps to improve their personal exploitation of open sources in support of the all-source intelligence process.

Appendices A and B are provided for background information. This initial chapter serves as the introductory element of the handbook.

1002. Definitions

It is important for the professional intelligence analyst to remember that the final intelligence product is supposed to represent a refined process which integrates requirements analysis (defining what the customer needs to know), collection management, source validation, analytical integration, and presentation.

For the purposes of this handbook, the following definitions are provided:

-- *Data* is the raw print, image, or signal. Data can be classified, as in a technical intelligence signal intercept, or unclassified, as in a report from the Foreign Broadcast Information Service (FBIS) on a public television report. Please note that open source data includes commercial imagery such as is available from SPOT Image Corporation.

-- *Information* is data that has been collated, processed, in order to produce a report that is of generic interest. Information can be multi-media, with integrated graphics and imagery, or simply a print report including interpretation of imagery.

-- *Intelligence* in this context is used to distinguish those products which tailor information in order to support a specific decision by a specific customer.

Nowhere is it written that "intelligence" must be classified. A good intelligence product can be based exclusively on open sources, or only on signals intercepts--it is of course likely that the best intelligence will be "all-source" in nature, integrating an open source foundation with unique value-added insights from classified sources.

The *official* definition of *open source information*, established in Director of Central Intelligence Directive 2/12 (effective 1 March 1994) is: "publicly available information (i.e. any member of the public could lawfully obtain the information by request or observation), as well as other unclassified information that has limited public distribution or access". The latter is referred to as "grey literature" and includes non-proprietary information from companies and other organizations.

1003. Brief History of U.S. OSINT

The Office of Strategic Services (OSS), when first formed, was intended to serve primarily as a coordinator of information, and was initially constructed around a Research and Analysis Branch which relied almost exclusively on open sources. In fact, when the OSS later had significant but scarce clandestine collection capabilities, they utilized *The New York Times* to prepare "secret" reports to satisfy many of their customers' requirements which did not merit the risk or expense of clandestine collection.[1]

Over time, and after the Central Intelligence Agency (CIA) was created by the National Security Act of 1947, the responsibility for open source collection became fragmented between the federal departments, such as the Departments of State, Defense, and Commerce; and selected elements of the CIA which specialized in open source collection. The two most important, still existing today as elements of the CIA, are the Foreign Broadcast Information Service (FBIS), and the National Collection Division (NCD). The former monitors foreign print and broadcast media; the latter works with private sector parties to obtain unclassified information. Today the Community Open Source Program Office (COSPO) coordinates open source investments across the entire U.S. intelligence community. Most other organizations including the Defense Intelligence Agency (DIA) utilize External Research & Analysis (ER&A) funds to contract for open source collection and analysis from the private sector--however, these funds have been severely reduced in the 1990's as fiscal cut-backs and the desire to keep U.S. government personnel on board have led to great reductions in contracting for external (i.e. open source) assistance.

---

[1] Mile Copeland, *Without Cloak or Dagger: The Truth About the New Espionage* (Simon & Schuster, 1974), pages 47-48. Testifying to Congress in 1947, Allen Dulles himself stated "...in time of peace the bulk of intelligence can be obtained through overt channels...these overt, normal, and aboveboard means would supply us with over 80 percent, I should estimate, of the information required for the guidance of our national policy." As quoted in Peter Grose, *Gentleman Spy* (Houghton Mifflin, 1994).

In recent years, the *"information explosion"*, together with major political upheavals within formerly denied areas, have made a vast quantity of open source information available to the public and to the intelligence community. Latin American investigative reporting, processed by Department of Energy laboratories, has been used by the U.S. Southern Operations Command to support Drug Enforcement Administration (DEA) interdiction operations; open source information is playing a critical role in countering proliferation, and in understanding transnational crime and especially financial crime.

Today, within the intelligence community and within Congress, there are differing views on the degree to which the intelligence community should collect and exploit open sources. Most observers, however, agree that the U.S. Intelligence Community should *not* be the focal point for open source collection *per se*, but that it *should* maintain a core capability to exploit private sector capabilities and to integrate global all source information into the all-source collection and production process. In practical terms, this means that *intelligence consumers are expected to manage and fund their own open source collection and production endeavors.*

1004. OSINT & All-Source Analysis

Open Source Intelligence, or OSINT, is an important part of the all-source intelligence process which includes clandestine Human Intelligence (HUMINT), Imagery Intelligence (IMINT), and Signals Intelligence (SIGINT). There are other important sub-disciplines, such as Measurements and Signatures Intelligence (MASINT) which analysts must understand and integrate to produce the best-possible intelligence.

Dr. Joseph Nye, then (1994) Chairman of the National Intelligence Council, used the jig-saw puzzle analogy to explain the relationship between OSINT and the classified disciplines. He likened open sources to the outer pieces of the puzzle, without which you can neither begin nor complete the puzzle. Classified sources, however, were essential to fill in the hardest to understand middle of the puzzle, and to complete the picture.

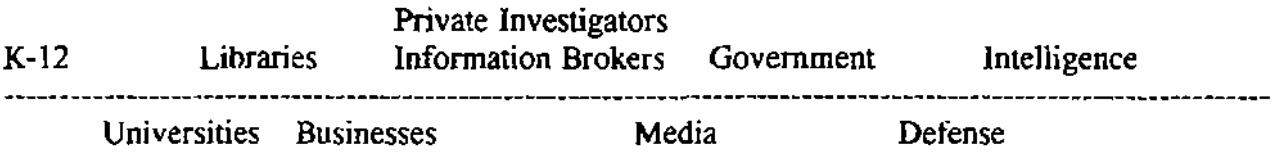
Mr. Paul Wallner, a member of the DIA Senior Executive Service, and the first Open Source Coordinator for the Director of Central Intelligence, described OSINT as "the source of first resort". His original conception was later adapted by a private sector commentator into the more dramatic phrase, "do not send a spy where a schoolboy can go'> Both drive home the point that open sources should be used to the fullest possible extent before risking and expending the more precious classified capabilities.

Dr. Joseph Markowitz, the current Director of COSPO, in addition to publishing the *Community Open Source Strategic Plan* (February 1995), has studied the utility of open sources in relation to traditional and emerging target sets, and concluded that open sources offer their greatest value as gap-fillers and initial orientations against Tier 4 Countries. Tier 4 Countries are those Third World countries which have not rated coverage by scarce classified capabilities, but to which the military must often deploy.

In brief, open sources are not a substitute for classified capabilities, but they can provide a valuable foundation and context for rapid orientation of the analyst and the consumer, and for the establishment of collection requirements which take full advantage of the unique access provided by classified sources. Analysts must be careful about relying exclusively on classified sources, especially against Tier 4 countries, because often the narrow range of classified sources may mislead the analyst into accepting a narrow interpretation of events.

1005. Knowledge Terrain: The Information Continuum

The figure below illustrates the "information continuum" which comprises the knowledge terrain of the private sector within which each all-source analyst must learn to navigate if they are to make the most effective use of classified as well as open sources. Appendix B has more detail on private enterprise intelligence capabilities.



Schools and Universities are a source of both labor (student as well as faculty), and data. Mercyhurst College, for instance, which has the only undergraduate degree in the USA focused on producing trained intelligence analysts, has its students using open sources to produce newsletters on narcotics and other topics of interest to law enforcement agencies. Universities across the country--and around the world--serve as "centers of excellence" in various areas of interest to intelligence community analysts. Knowing how to access and exploit such distributed capabilities can save the analyst time, save the community money, and improve support to the consumer. *Libraries* offer similar opportunities, including the Special Libraries maintained by major multinational corporations and international non-governmental organizations.

Businesses maintain a great deal of information, much of it unpublished but available for the asking, on both conditions in the countries in which the do business, as well as about key personalities. During the war in Southwest Asia, it was businesses which provided the most critical information about Iraqi command & control systems, including the detailed plans for his installed communications and computing infrastructure.

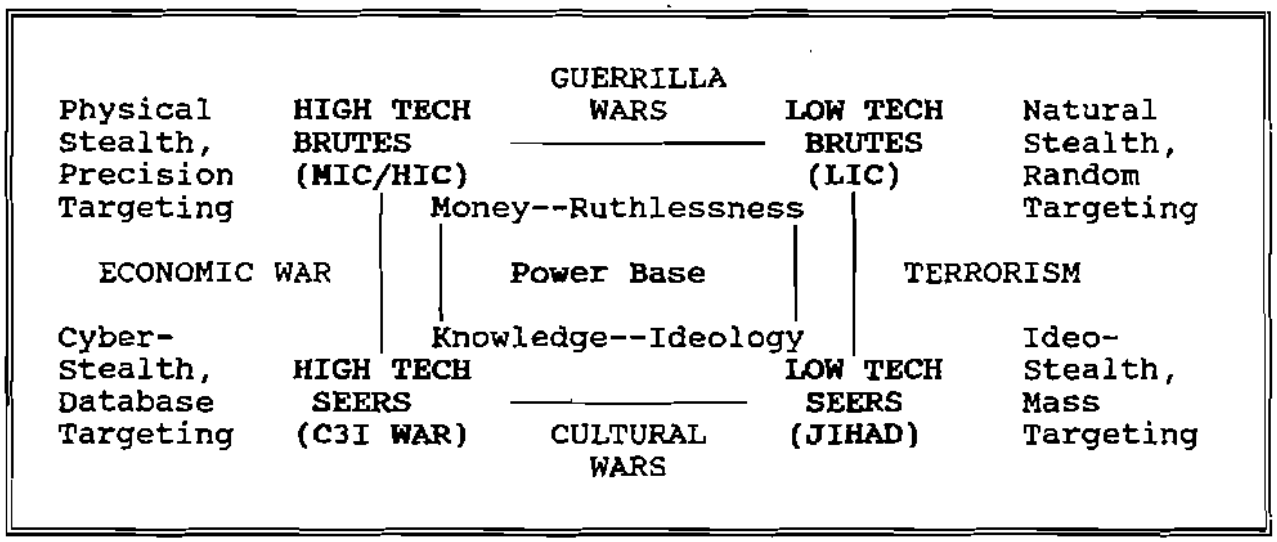
Private Investigators and Information Brokers spend their careers at someone else's expense developing expertise in certain areas and research methods. The *Burwell Directory of Information Brokers*, for instance, has specialists worldwide indexed by topic, country, and language fluency. They constitute a "ready reserve" for the intelligence analyst.

Few people realize that *media reporters* publish less than 10% of what they know, and are often happy to accommodate requests for information "on background". Although direct

contact by the analyst may not be appropriate, the analyst can use services such as LEXIS-NEXIS to identify experts in the media (e.g. the stringers covering Burundi or Somalia) and then task appropriate agencies with interviewing these experts along specific lines. Finally, analysts should catalogue their *counterparts* in other agencies and governments.

1006. OSINT and the Military I

The figure below illustrates the four warrior classes which confront both the military and law enforcement, and helps us understand that the intelligence challenges facing the military in the 21st Century require greater and distinct capabilities than those from the Cold War.



It is significant that our entire defense establishment, and our entire intelligence community, have been optimized over forty years to deal with just one of these warrior classes, the high-tech brute. The other three warrior classes represent significant intelligence challenges--the criminal, for instance, represents a "low-slow singleton" target which does not move high enough or fast enough, or emit enough of a signature, to be detectible by most of our space-borne early warning systems. The economic and computer warriors, the high-tech seers, represent both problems of jurisdiction, and problems of collection.

This training does not address policy, doctrine, or acquisition issues. The point of this chart is to both illustrate the challenges confronting intelligence analysts as they adjust to new targets; and also to make the point that open sources are--fortunately--both plentiful and pertinent when attempting to understand the three increasingly threatening warrior classes.

The information explosion has been a mixed blessing. Although a great deal of information about virtually every topic is available for purchase if not for free, the validity and utility of much of the information is questionable, and requires both heavy screening--

much of which cannot be done by machines--as well as translation and interpretation. All-source analysts today are trained to use classified tools and methods, and do not have optimal access to open source experts and databases.

Open source exploitation by DIA and the U.S. intelligence community is certain to improve, as this chapter concludes, because of the value of unclassified intelligence in support of unilateral information-based warfare, coalition operations, joint civilian-military operations, and support to law enforcement operations.

This chapter does not recommend that all-source analysts spend less time on classified sources and more time on open sources, but rather that they leverage private sector collection and production capabilities in order to optimize the collection management of classified capabilities.

1007. OSINT and the Military II

OSINT can be very important at each of the four levels of intelligence analysis. Appendix A provides additional discussion

At the strategic level, analysts have found that a careful review of open sources, even from societies subject to censorship, can provide a sound understanding of political plans and intentions. Open sources are especially helpful in forecasting cultural turmoil and providing warning of revolution or upheaval. Also at the strategic level, open sources are very useful for developing the *encyclopedic generalizations* needed to develop theater capabilities for multiple contingencies. Finally, open sources are very helpful in orienting both troops and the public.

At the operational level, open sources can help force planning as well as the coordination of joint and coalition operations. It is open sources, for instance, which have established that the average temperature for expeditionary operations in the Third World is 80°, with high humidity. Since most aircraft are designed for "warm"days rather than "hot" days, this means that their range and lift are significantly reduced.

At the tactical level, open sources have proven valuable in obtaining commercial imagery and related products, including 1:50,000 combat charts with contour lines, for Third World areas for which the Defense Imagery Agency does not have digital data or ready maps.[2] Analysts requiring imagery and tactical maps to support a commander should not

---

[2] Of 69 countries established in 1990 by the USMC as being "high probability" deployment areas, DMA had no data or maps for 22 of the countries; old maps for the ports and capital cities only of another 37; and very old maps for the remaining ten countries such as Cuba, North Korea, and Jamaica. *Overview of Planning and Programming Factors for Expeditionary Operations in the Third World* (MCCDC, March 1991).

hesitate to request commercial imagery. Commercial imagery products also include multi-spectral imagery sensitive to heat differences, and automated three-dimensional "fly-by" videos of approaches to airfields and landing areas.

At the technical level, open sources are very important to developing information-based warfare capabilities and plans for attack; they are also useful in establishing realistic mobility estimates and weapons range and intervisibility (line of sight) needs.

1008. Militarily Useful OSINT: Two Examples

Two examples are offered here of how useful OSINT can be, either as the foundation for a classified collection effort, or "in a pinch" when classified offerings are non-existent and unlikely to be quickly forthcoming. The first example, Somalia, was developed in support of a Marine Corps Wargame in which LtGen Zinni requested a post-mortem on his performance in Somalia. The individual invited to serve as the United Nations Commander for this wargame requested and received the following products via overnight mail:

-- From Jane's Information Group, a one page map of Somalia clearly demarcating the nine clan areas; a one page order of battle for each clan including key artillery and mobility systems; and a compendium of one paragraph summaries with citations of every major article about Somalia published in any Jane's publication in the previous two years.

-- From Oxford Analytica, twenty-two two-page summaries "suitable for a President or Prime Minister" covering U.S. foreign policy toward Somalia; UN operations in Somalia, and US operations in Somalia.

-- From *The Economist* Intelligence Unit, a country study which, while shallow, had valuable insights regarding both the limitations and the fragility of the infrastructure.

Subsequently, in a second example, Burundi, the Commission on Intelligence requested and received, through overnight mail, products similar to the above from Jane's Information Group and Oxford Analytica, and in addition:

-- From Eastview Publications, a list of all immediately available Soviet maps of Burundi, with their scale and price.

-- From LEXIS-NEXIS, a listing of the top 25 journalists reporting on Burundi.

-- From the Institute of Scientific Information, a listing of the top 10 academic knowledgeable about all aspects of Burundi.

Subsequently, it was determined that complete coverage of Burundi was available from SPOT Image Corporation, data already collected and stored, from which both 1:50,000 combat charts with contour lines, and landing point fly-by simulations could be created.

1009. Representative Open Sources I

Contract information for all of the references and organizations discussed in this handbook is provided in Appendix D. Most libraries will not have these references or access to these organizations--asking them to subscribe or develop support contracts is something anyone can do to improve your entire organization's access to key open sources.

The British Library specializes in monitoring international publications, and does especially well with respect to Africa and Asia, and conferences about both scientific & technical topics, and general topics including military matters. They are an especially good source now for examining the contents of conference *Proceedings*, and offer their products in CD-ROM.

Oxford Analytica is unique for having a global network of almost 1,000 overt human experts on-call to prepare concise forecasts and situation reports suitable "for Presidents, Prime Ministers, and you". They specialize in political-economic reporting.

A number of **directories** can help the analyst rapidly identify experts, many of whom are not likely to charge for quick informal inquiries.

-- Specializing in **electronic access** is the book *Find It Fast: How to Uncover Expert Information on Any Subject.*

-- For rapid identification of predominantly **academic experts**, the *Social Science Citation Index* and the *Science Citation Index* are unmatched--they are particularly useful in that they provide the expert's address, prior publications, and list of citations by others, establishing their peer recognition as authorities.

-- **Government authorities** world-wide can be identified, with their full titles, addresses, and voice and fax numbers, through *Worldwide Government Directories*. Also available from the same organization is a biographic reference, *Profiles of World Government Leaders*.

-- Finally, the best private sector **information brokers** world-wide, with complete contact information and indexes identifying their topical and language strengths, can be found through the *Burwell Directory of International Information Brokers.*

1010. Representative Open Sources II

International research sponsored by other governments, international non-governmental organizations, multinational corporations, and universities has been poorly documented in the past; now a new service, *ResearchBase*, is available which allows analysts to determine if there are projects underway which can be built upon rather than duplicated.

The **Internet** is--like the information explosion which it represents--a mixed blessing. Internet resources are in constant motion, and no search path can be duplicated from one day to the next. However, a number of entrepreneurs are beginning to offer useful guides. Among the three best are the *Clearinghouse for Subject-Oriented Internet Resources*; the *Guide to Network Resource Tools*; and *netguide*.

Info-South is an example of how universities can provide distributed database and media monitoring services to analysts. This service provides english-language translations of key Latin American newspapers, and also biographic profiles of Latin American leaders.

Business community information can be accessed through the Special Libraries Association, over 15,000 corporate librarians, through the publication *Inside Information: Profiles of Association Libraries and Information Centers*.

Maps are always very useful, both to the analyst developing the all-source product, and to the consumer, who often does not know where to go once DMA tells them no maps are available. The following two sources are helpful:

-- **Eastview Publications** can rapidly identify and obtain maps of the Third World, generally down to the 1:250,000 level but sometimes better, which were created by the Soviet Union.

-- **SPOT Image Corporation** has most of the world digitized at the 10 meter scale, and from this scale can create 1:50,000 combat charts with contour lines, targeting packages for precision munitions, and three-dimensional "fly-by" visualizations of landing site approaches.

Unclassified **photographs** can add value to intelligence reports; the archive of DoD photographs is now available through the National Technical Information Service (NTIS); a vast collection of international photographs is available from United Press International.

1011. Representative Open Services 1

One of the most important changes in the open source world pertinent to the analyst is not the dramatic increase in the availability of raw data, but rather the significant improvement in the variety and capabilities of open services able to provide value-added collection, processing, and production.

Unlike direct acquisition requests for sources, these services generally have to be contracted for by the organization before they can be exploited; once a contract is established, however, individual analysts can then obtain direct support on demand.

Academic Journal Monitoring by Uncover Reveal or the Institute for Scientific Information allows analysts to receive tables of contents--via fax or email--for various

journals of interest, from which articles can be selected for acquisition.

Commercial online searches can be carried out directly by the providers, such as LEXIS-NEXIS or DIALOG, or through intermediaries such as NERAC. The former tend to be more efficient at exploiting their own databases, the latter has the advantage of charging a fixed price per year.

Daily current awareness profiles are a very good way of following the international media. The profiles generate daily lists of key articles, which can then be ordered if of interest. Besides LEXIS-NEXIS and DIALOG, the two most popular services are *Heads Up* from Individual, Inc., and *NewsEdge* from Desktop Data.

Document Acquisition world-wide is something private sector organizations do very well. Instead of burdening an Embassy with finding an obscure but essential document, organizations such as FIND/SVP can be relied upon.

Environmental information, of increasing importance to some intelligence consumers, depends heavily on commercial imagery as well as databases of environmental research. CIESIN (Consortium for International Earth Science Information Network) is among the leaders in this area.

European Economic Research is a specialty of Fuld & Company--specific research projects might be best conducted through a preliminary open source effort such a private sector company, followed by classified tasking.

1012. Representative Open Services II

Grey literature refers to publicly available (non-proprietary) documents printed in very limited numbers and generally not available outside the country of publication. ACCESS International, and Eastview Publications, are among the best in this area.

Infrastructure surveys, including "ground truth" photography and surveying, can be done by some private sector organizations which employ former SAS (Special Air Service) personnel traveling discreetly under tourist or business cover. E2G, a British company, is one of the few that is openly available. In the US, BDM Federal specializes in remote infrastructure surveys, using legally obtained open sources.

International **investigations**, including economic surveys and technical acquisition projects, can be carried out by private firms such as Kroll Associates or Parvus-Jericho.

Refugee debriefings world-wide can be a gold-mine of raw intelligence. Organizations such as Rapport Research & Analysis, based in the UK, specialize in organizing teams of trained military interrogator-translators in any language, and then conducting debriefings in the major international cities where refugees are legally accessible.

Third World economic analysis can be contracted to such firms as SIS International, which had created a network of host-country business research organizations with special strengths in Asia and Africa.

Telephone Surveys are often a very low-cost means of creating new knowledge and obtaining a rapid sense of where a specific topic stands among leading authorities in the field. Telephone research is a special skill-set which includes a sound understanding of how professional associations around the world are organized and can be exploited. Risa Sacks Associates is one of the top US firms with this unique capability.

Trade database creation is a specialty of the Monterey Institute of International Studies, which is already very well known to the intelligence community for its use of graduate students fluent in Arabic, Russian, and other hard languages to create their proliferation database.

Special comment: in the open source world, niche providers outside the beltway are generally more capable, and cheaper, than large corporations based in Washington, D.C.

1013. Intelligence in the Age of Information

The two major differences between intelligence during the Cold War and intelligence today are as follows:

-- During the Cold War, the enemy was a well-known conventional power with nuclear capabilities, and the threat was relatively static over forty years. This led to the creation of an intelligence community optimized to do repetitive classified collection against a denied area, with a strong focus on major weapons systems with strong electronic and heat signatures. Today, as addressed by the earlier discussion of the four warrior classes, the threat is much more diverse, and consists of many smaller groups that are more difficult to identify, track, and analyze.

-- During the Cold War, the necessary information for intelligence analysis was generally not available through public sources; today much of what is needed to satisfy intelligence consumers is available from open sources, and the intelligence community is often in competition with open sources reaching the consumer directly.

Today, analysts must be responsive to their consumer's desires for intelligence reports that are short, fast, and often unclassified, for the latter can then be shared with Congressional staff and media as well as the public, and thereby help to influence policy change. *It is the consumer, not the analyst, who should make the decisions regarding preferred length, level of classification, and time permitted for report preparation.*

Classified information, which cannot be duplicated by open sources, represents a unique value-added capability--it will be most successful if it builds on open sources, rather

than competing with open sources or--worse--ignoring open sources and finding itself out of context and under-priced by "good enough" open source intelligence.

The most successful all-source analysts will develop methods of harnessing distributed experts and data in the open source world; do "just in time" analysis and production that supports specific decisions being faced by their consumers each day; stay close to the consumer to monitor and add value to the flood of open source reaching the consumer directly; and will master the art of integrating unclassified and classified products so as to give the consumer added power through more disseminable open source intelligence, and added confidence through the unique value-added insights that only classified all-source intelligence can provide.

1014. Changing Role of the Analyst I

The traditional all-source analyst has generally been focused in the task of monitoring and integrating classified intelligence (HUMINT, SIGINT, and IMINT) reaching their classified workstation, and has relied only to a very limited extent on the full range of open sources and services available through the private sector. At the same time, because of time, resource, and security constraints, the analyst has generally not interacted on a regular basis with either their private sector subject-matter counterparts, or their customers.

There is a growing belief that the role of the analyst must change in this decade, moving away from a relatively isolated emphasis on processing hard-copy and electronic intelligence into "products" that are then passed anonymously to a generic set of consumers through an impersonal broadcast, and toward a much more active--a much more interactive--role as a manager of people and resources.

Specifically, since no analyst can hope to master both the flood of classified and the flood of unclassified information, some envision the "reinvented" *analyst as a manager of a network of overt sources which serve as a foundation (not a substitute) for all-source collection and production.* Such a network, maintained by distributed centers of excellence in the private sector, at no expense to the government, could serve as a filter of subject-matter open sources, provide "tiger teams" for short periods to develop surge knowledge bases (e.g. Somalia, Rwanda), and help the analyst frame key questions which cannot be provided by open sources and must be tasked to classified capabilities.

1015. Changing Role of the Analyst II

At the same time, in order to manage and mobilize such a network of overt sources, the *analyst as a manager of resources* must emerge--an analyst that knows who the top experts are, and has the authority to hire them "on demand" for very specific and relatively inexpensive direct support tasks.

Although the intelligence community has received very fine support from a number of

major beltway corporations, these corporations have constituted an "outer ring" of institutionalized capabilities with the same limitations as the intelligence community itself.

The envisioned change in the role of the analyst brings with it the possibility of more direct analyst control over external research & analysis, with more analyst authority over day-to-day direct support contracts with individual experts rather than anonymous institutions.

The significant advantage of this approach is that the community pays only for what it uses, when it is used--this allows the analyst to take advantage of experts whose overhead--whose lifetime of acquired expertise--has been funded by someone else, someone other than the U.S. taxpayer.

1016. Changing Role of the Analyst III

Given the vast amounts of open sources that reach the consumer, there is increased interest in developing analysts able to serve as a *manager of consumer relations*, with three specific objectives:

-- to win the consumers confidence on a day to day basis, and

-- to ensure that the consumer is receiving appropriate decision support daily; and

-- to monitor and exploit the open sources reaching the consumer.

It is very important for analysts to understand that consumers have and value their own open source connections, and they have and like to pay attention to their own departmental analysts.

The analyst, by developing a very close and constant relationship with their consumer, can not only gain access to the open sources that reach the consumer and do not reach the intelligence community--but can help the consumer avoid being taken in by open sources that might at first glance appear authoritative but which can--with the insights gained from all-source collection and analysis--be called into question.

1017. Changing Role of the Analyst IV

The professional intelligence analyst will always be different from scholars, journalists, and other expert commentators because only the professional intelligence analyst will have access to classified intelligence sources and classified intelligence tools.

The professional intelligence analyst that ignores open sources and relies exclusively on classified data for their raw input will not be competitive. In contrast to open sources, which represent the "information explosion" with all its pluses and minuses, the classified sources tend to be very finely focused and to produce narrow slices of information which

have to be melded and integrated. If you fail to use open sources to provide the context for analysis as well as the foundation for estimative intelligence. you will in all likelihood either miss the mark, or miss important tip-offs suggesting the need for classified tasking.

Open source information, therefore, should be seen as a pre-amble to fulfilling the analyst's ultimate responsibility as a *manager of classified capabilities* which lead to the production and delivery of an all-source product.

The role of open source information in the final product is important. At the Central Intelligence Agency, the general rule of thumb is that open source data comprises 40% of the final all-source intelligence product. Within the Defense Intelligence Agency, the general percentage, according to one graduate thesis survey, is 30%. In Canada, according to Mr. Ward Elcock, the director of the Canadian Security and Intelligence Service, open sources comprise 80% of the final all-source product.

What this means is that open sources are both a critical element in targeting classified capabilities, and also a critical element in explaining classified information in an all-source context.

Open sources are also very helpful when the analyst has classified sources which cannot be shared by the consumer with a specific audience (e.g. international organizations or the press)but which confirm the accuracy and utility of specific open source reports over others. Although the fact that the intelligence community lends its authority to specific open sources differentiates those sources at the time, this is sometimes the only way to provide intelligence in support of certain requirements.

1018. Overt Human Networks: Some First Steps

Most analysts know who their counterparts are at the other major intelligence agencies, and in the Joint Intelligence Centers (or, for law enforcement missions, the Regional Intelligence Centers). However, most analysts have not been afforded the time or given the incentive to identify and exploit their subject-matter counterparts in the private sector, and have perhaps also been concerned about the security implications of such contacts.

The analyst interested in evaluating the potential of the private sector to enhance their performance as an all-source analyst can take several steps in turn, with increasing management involvement, to achieve a unique status as a "hub" for both open and classified sources pertinent to their area of interest.

First, without engaging in any direct contacts of possible security concern, the analyst can inventory the private sector's capabilities in their area of interest, and rapidly establish a listing of key people--academics, journalists, business experts--who have something to contribute. At the same time, the analyst can inventory the availability of geographic information for their area of responsibility—as a former Director of the Marine Corps

Intelligence Center told the Council of Defense Intelligence Producers in 1992, "I don't care how much order of battle data you give me, if I cannot plot it on a (1:50,000) map, it is useless to me."

Jane's Information Group, which publishes both *Jane's Intelligence Review* and the *SENTINEL* series of *Country Reports*, also has an online database, and the capability to prepare special reports containing the 80% of the information they have about a country, but cannot publish for a variety of reasons including source protection.

Once the analyst has a good sense of who the top people are that might be of service as a personal network of overt sources, a few of these can be selected, and a specific plan proposed to management which seeks to fund individual familiarization meetings, possibly an exchange of unclassified data, and contingency arrangements for on-call support when required by a contingency.

Sponsorship of inter-agency subject-matter conferences, including an unclassified day with external experts, is a good way for the analyst to position themselves as focal points for voluntary information sharing.

1019. OSINT Among Selected Allies

In general, other intelligence communities are not any better off than the U.S. intelligence community with respect to open source exploitation. However, a number of them illustrate how improvements might be made in our own future endeavors.

Canada has gone on record publicly, stating that 80% of its all-source product comes from open sources; Canada is also a leader in doing unclassified strategic intelligence production which is receiving wide circulation and praise because it can be shared.

Israel has perfected the utilization of host-country information brokers, and exploitation of local laws such as the U.S. Freedom of Information Act, to obtain great quantities of information at almost no cost.

The United Kingdom, influenced by the open source movement within the U.S. intelligence community, has leaped ahead with the first public tender (Request for Comments) for an Open Source Information Center for the Ministry of Defence.

The United Kingdom Open Source Information Center is especially important because it could serve as a model for the United States of America, the other partners in the North Atlantic Treaty Organization, and the United Nation. An initiative to develop a center of expertise at the Joint Analysis Center (Molesworth) would be especially useful as a vehicle for linking United Kingdom and U.S. open source acquisition programs in the military arena.

1020. OSINT In Asia

In Asia there are several examples of strong approaches to open sources as a foundation for both national security and national competitiveness.

Australia, and specifically the Defence Intelligence Organization, has collected a significant amount of open source information on Papua New Guinea, the Spratley Islands, and other areas of interest to the U.S. Pacific Command, but they have no focal point for open source burden sharing.

Japan relies heavily on its private sector, notably the trading companies, for its open source collection, with a stated daily collection of 6,000 newsprint-size pages. Japan has also perfected "dissemination trees" in which each major organization collecting open sources from other countries--whether in the government or in the private sector--has roughly sixty other organizations to which copies are immediately routed.

Singapore relies primarily on open sources, and focuses heavily on economic intelligence. As a major banking center in its own right--and the likely base for those who choose to leave Hong Kong once it is turned over to the Republic of China, Singapore understands the value of providing its business community with a robust information environment. The National Computer Board (NCB) has representatives in every government department and is rapidly integrating all government databases. They will do the banks next--focusing on encyclopedic marketing information--and then elements of the private sector on a voluntary basis.

Taiwan has not been adequately studied, but it should be high on our list of countries to be observed because in Singapore, Taiwan is considered the "model" for open source collection.

1021. OSINT in Europe

France is actively orchestrating economic intelligence collection and education. In 1993, after the publication of the book *Friendly Spies*, and coincident with the privatization of a number of key French companies, the Prime Minister directed increased focus on the utility of open sources of intelligence. A conference was sponsored in October 1993 at which General Heinrich, then Director of Military Intelligence, and several other authorities including the leading U.S. advocate for open sources, made presentations to 300 leaders from across France on the subject of reinventing intelligence and using open sources. The government continues to play a strong role in organizing economic and information strategies, and in encouraging economic intelligence education.

The Netherlands has reorganized its collection to make open sources co-equal with technical and clandestine collection; uses a task force approach to analysis that beings with open sources; and optimizing its exploitation of the Internet by having specialists do

centralized discovery of Internet resources, while analysts do the decentralized exploitation of the resources once specifically identified.

Sweden, although small, has optimized its performance in science & technology by coordinating government, business, and academic collection of open sources through an informal committee called the Swedish Open Source Coordination Forum. The Swedish government is considering the "privatization" of the existing scientific & technical attache service, motivated largely by the need to decrease government spending. Swedish scientific & technical attaches have been aggressive about patrolling the Internet in search of both data and points of contact.

1022. OSINT Within DIA 1

The Program Manager for Open Source Intelligence within the Defense Intelligence Agency is Ms. Alice Cranor, whose contact information is provided here. She serves as the DIA representative to the Open Source Council, which is the advisory body formed to support the Community Open Source Program Office (COSPO). Each agency and service has a single representative to the Council. In addition to an agency-level focal point, every branch within DIA has an OSINT focal point.

The only survey to date of open source intelligence exploitation within DIA was completed in August 1995. "Open Source Intelligence: An Examination of Its Exploitation in the Defense Intelligence Community", by Major Robert Simmons, USA, is a Joint Military Intelligence College thesis which surveyed all analysts in DIA and its two production elements, the Armed Forces Medical Center and the Missile and Space Intelligence Center.

Maj Simmons' findings are shown here:

-- Less than 30% input from open sources

-- Such open sources as are used come through SAFE from FBIS

-- Most analysts do not have Internet access

-- Most analysts rarely discuss issues with external experts

-- Most analysts are not aware of other open source resources

-- Most analysts are generally satisfied with their level of access to open sources

Maj Simmons' concludes that the analytical components of DIA are generally "ill-prepared and ill-supported to make full use of any information outside of the small, restrictive and limited domain of classified intelligence sources. The cultural attitude at DIA generally reinforce(s) using classified information as the first and last stop in the analytical process and

open sources are used rarely to fill the gaps. The result is an intelligence product limited in its scope and overly expensive."

1023. OSINT Within DIA II

Although the thesis results are negative with respect to existing DIA practices, and funding constraints do not appear to offer significant relief in terms of new initiatives to exploit open sources in support of military intelligence, there has been a significant increase within DIA of appreciation for the potential of open sources.

Maj Simmons' thesis concludes with these findings:

-- Tier 3 and 4 countries, where there is a very high probability of U.S. military involvement in contingencies, are not covered by established classified collection priorities.

Almost all of the countries of concern to the Marine Corps, as defined in the *Expeditionary Force Mission Factor Intelligence Analysis Requirements Study* (Marine Corps Intelligence Activity, 15 September 1994), are Tier 3 and 4 countries. In addition to a lack of encyclopedic intelligence, there also exist severe shortfalls in mapping, charting, & geodesy (MC&G) data needed to produce 1:50,000 combat charts for combined arms coordination and ground maneuver. Fortunately, commercial imagery, including 10-meter resolution imagery from SPOT Image Corporation, is capable of providing 1:50,000 maps with contour lines within hours or days--HOWEVER such commercial products still require assistance from classified capabilities orchestrated through the Defense Mapping Agency in order to integrate "ground truth" precision points needed to ensure the accuracy of the maps, as they are to be used for coordinating combined arms fires.[3]

1024. OSINT Within DIA III

Continuing with the conclusions from Maj Simmons' thesis:

---

[3] Two major surveys have been done in recent years of MC&G short-falls in the Third World. The first was done by the Special Operations Command (J-2) in 1987-1988; and the second, focusing specifically on expeditionary contingencies, was done by the new Marine Corps Intelligence Center (now Activity). The Marine Corps Study, published as *Overview of Planning and Programming Factors for Expeditionary Operations in the Third World* (Marine Corps Combat Development Command, March 1990), found that of the 69 countries of concern to the Marine Corps, there were no combat charts at all for any portion of 22 of the countries; old combat charts for ports and capital cities only--not for maneuver areas--for another 37 countries; and very old combat charts for the remaining ten countries where higher priorities has permitted full coverage at one time--countries such as Cuba and North Korea.

-- OSINT is often the only resort in the early stages of a crisis, and critical in support of rapid-response planning for deployment--it should be noted that commercial imagery and 1:50,000 combat charts with contour lines from commercial imagery can be obtained within hours or days of demand.

-- Private sector publications such as those produced by Jane's Information Group often provide defense intelligence analysts with their first tip-offs on weapons modifications and sales.

-- Open sources serve as valuable tip-offs about national leaders' intentions, since actions are often justified in advance to their public through the press.

-- The majority of Third World terrorist information is obtained from FBIS and wire services (proliferation specialists say the same thing)

-- OSINT is essential when unclassified products are needed for coalition operations or briefings to uncleared Congressional members and staff.

What is the bottom line here: improved exploitation of OSINT as part of the all-source product is not going to be driven by top-down directives, but rather through bottom-up initiatives. Every analyst must understand the value of open sources, and the range of open sources and services available to support their subject-matter production requirements. Through a concerted effort by all analysts to request funding for access to open sources and services, defense intelligence will gradually be revitalized.

1025. OSINT and the All-Source Product

Concluding in this vein, recognizing that the analyst is the focal point for change in how we prepare the all-source product, this chapter suggests that each analyst must:

-- Strive to understand the information continuum and how private sector subject-matter experts and databases can provide direct support to the all-source process;

-- Develop a personal "map" of open source experts of possible value, including complete contact information. This is something which can be done without direct contact, as a pre-amble to securing management and security approvals for interaction.

-- Submit specific proposals to management for employing specific experts in specific ways to enhance the all-source intelligence product; and finally,

-- Work with security to establish comfortable ground rules for both planned and spontaneous contacts and unclassified information exchanges with external experts who will rarely have--or accept--security clearances.

The intelligence analyst is the critical linch-pin for reinventing the intelligence process and fully integrating open sources as a foundation for the all-source product. Those analysts that fully understand open sources, and develop proposals for exploiting open sources, will find themselves able to manage networks of overt open sources, able to justify and to manage modest resources to mobilize those open sources on demand; able to significantly improve their management of consumer relations and their exploitation of open sources reaching the consumer directly; and able to dramatically improve their management of classified capabilities, both in collection and production.

Open sources are <u>not</u> a substitute for classified sources--they are an essential and valuable foundation for making the most of our scarce classified capabilities.

Chapter 2

ACCESS: INTELLIGENCE IN THE AGE OF INFORMATION

2001. Purpose of the Chapter

The purpose of this chapter is to present a more in-depth look at why open sources are critical to the all-source analysis endeavor, and how all-source analysts can optimize their exploitation of open source information.

Included in this overview will be: definitions distinguishing between data, information, and intelligence; discussions of how the art of intelligence is changing in the face of the "information explosion", the four kinds of information categories that an all-source analysts can consider accessing, and the three elements of information value; a discussion of the nine levels of open source information; an examination of possible collection management strategies which integrate open sources into the all-source collection management task and exploit windows of opportunity in which material is available in open sources just prior to being classified or censored; discussion of the four major consumer groups and their intelligence productions needs in relation to open sources; an examination of the four "warrior classes" and how open sources apply to intelligence analysis of each; discussion of the four types of overt human sources the analyst will encounter; an examination of how open source intelligence (OSINT) can help conserve scarce classified resources, and how a national information strategy can increase the amount of open source information available to the defense intelligence community; and concluding comments on optimizing OSINT in the all-source analysis process.

2002. Definitions

For the purposes of this chapter, the following definitions are reviewed. This is a review of definitions provided in Chapter 1.

-- **Data** is the raw print, image, or signal. Data can be classified, as in a technical intelligence signal intercept, or unclassified, as in a report from the Foreign Broadcast Information Service (FBIS) on a public television report. Please note that open source data includes commercial imagery such as is available from SPOT Image Corporation, and from which 1:50,000 combat charts with contour lines can be quickly constructed.

-- **Information** is data that has been collated, processed, in order to produce a report that is of generic interest. Information can be multi-media, with integrated graphics and imagery, or simply a print report including interpretation of imagery.

-- **Intelligence** in this context is used to distinguish those products which tailor information in order to support a specific decision by a specific customer.

These definitions are important because the analyst will often deal with consumers and with questions where the best answer is an unclassified answer. The all-source analyst must avoid falling victim to the concept that only a classified answer has authority. The fact that the all-source analyst has access to classified information is what lends a special credibility to their selection of an open source and their provision to the consumer of an unclassified answer.

Intelligence consumers have important political and public responsibilities which frequently require candid discussions of "the threat" or "the situation" with individuals who are not authorized access to classified information. To the extent that the all-source analyst can provide the consumer with credible unclassified intelligence, the analyst will be facilitating the intelligence consumer's policy tasks.

2003. New "Rules of the Game"

As the defense intelligence community moves away from focusing almost exclusively on the former Soviet Union and "denied area" intelligence, the all-source analyst is faced with requirements from new consumers, about threats and situations in the past which previously did not warrant all-source collection and production. Examples of such old but now more important intelligence problems include proliferation, terrorism, transnational crime, environmental threats, and economic intelligence.

Here are four new "rules of the game":

-- The National Foreign Intelligence Board has stated for the record that open sources comprise 40% of the all-source product, at a cost of less than 1% of the National Foreign Intelligence Program. For some intelligence problems, such as proliferation, and for some allied intelligence services such as the Canadian Security and Intelligence Service, open sources comprise 80% of the all-source product.

-- The private sector has most of the real experts for those problems which are not traditional intelligence concerns. The Vice President has spoken about the need to "harness the distributed intelligence of the Nation". The all-source analyst needs to identify and exploit experts in the private sector and experts in allied governments.

-- Although electronic sources are fashionable, and most defense intelligence analysts rely almost exclusively on open sources collected by the Foreign Broadcast Information Service and delivered to their desktop workstation by the Secure Analysts File Environment (SAFE), in fact most open sources are in hard-copy, in a foreign language, and not available on the library shelves. Analysts must consciously define their open source requirements and set in motion the process to acquire the necessary open source material.

-- Analysts can no longer afford to do "just in case" collection and production. The demands on analysts are so extensive--almost overwhelming--that only a "just in time"

approach will permit them to satisfy consumers. This is especially true because information changes so quickly, that old archived information is usually overtaken by events. Analysts will do better going out to distributed databases at the last possible minute, and then integrating recent classified collection into their all-source product.

2004. Four Information Categories

The all-source analyst should understand that there are four information categories, and the relative cost and degree of difficulty for exploiting each category.

-- Open Source Information is legally and ethically available, at a low cost. The analyst that fully exploits open source information to establish a foundation for their all-source product can generally improve their understanding of the problem and its context at a low cost, and can often reduce requirements for classified collection.

-- Open Proprietary Information, can be legally and ethically obtained, but require a moderate cost to commission reverse engineering studies to extract the information from the product. This is a good alternative to riskier and higher cost espionage intended to steal the information from within the target organization. Examples: buying a French missile to study the missile guidance software and hardware; buying Russian imagery to calculate their overhead technical capabilities.

-- Closed Proprietary Information is only available from within the secure areas of the target organization, and requires espionage, at high cost, to obtain. Some intelligence services use private sector investigative agencies to obtain such information, under the guise of industrial espionage--a form of false flag operation. Examples: stealing source code for major computer applications; stealing designs for delicate machinery used to create scientific & technical instruments.

-- Classified information, collected by spies and satellites, is very expensive, and in the cast of Human Intelligence (HUMINT), often very risky. It does, however, have a very special value to the all-source analyst as its accuracy and reliability is high--this is especially the case with Signals Intelligence (SIGINT) products.

As analysts are thinking about an intelligence problem, they can benefit by drawing four circles around the problem definition. The outer circle, the largest, is the open source information domain. The analyst can annotate what open sources might offer insights to the problem. The next two circles moving inwards are open proprietary information and closed proprietary information. Finally, the smallest circle, classified information, can be annotated to show what precise and specific collection could help the analyst complete the intelligence puzzle. Using this method will help optimize the contribution of low-cost open sources while focusing demands on classified capabilities.

2005. Information Value

Here we want to consider the three elements which--taken together--comprise the value of information. Each is important because each can help the all-source analyst think about their collection management and production processes.

The raw content, a specific document, is often easy to obtain once it has been identified, but not so easy to identify. Any analyst who has ordered a commercial online search and received a listing of thousands of documents, with no means of sorting through them to determine relevance to the problem, will understand how difficult it can be to identify exactly the right document. Resources are scarce, and it is not cost effective to collect all possible documents and then review all personally. Analysts need to work closely with librarians and other open source collectors to refine the inquiry as much as possible. *Often, the best way of refining the inquiry is to consult a private sector expert--such as a defense industry expert--who is fully familiar with available content.*

The context within which specific content can and should be evaluated is often overlooked. For lack of both background and time, the analyst may not realize that specific cultural or political conditions give the content a meaning different from that which it might have in a U.S. context. *Again, consultation with a private sector expert--perhaps including a reputable journalist or a businessman resident in the area of interest--is often the best means of rapidly coming up to speed on context.*

Finally, we have timeliness. Analysts need to be sensitive to the fact that Foreign Broadcast Information Service reporting, while it contains value-added commentary, often arrives two to three weeks after it has been published. Internet news sources and commercial online services are more timely. "Near real time" media monitoring may not always be necessary, but analysts should consciously evaluate the timeliness with which they are receiving open source (and classified) information, and take steps to improve timeliness when it is important to the accuracy and relevance of their all-source intelligence production for the intelligence consumer.

2006. Open Sources

Here we briefly review nine levels of open source information. Future chapters in this course provide more detailed examination of sources such as the Internet.

The Internet is largely "free" once access is obtained, but analysts have to remember that "you get what you pay for". The reliability of Internet sources varies widely, and exploration of the Internet is very labor intensive, and can be misleading. For instance, analysts accessing the Internet through America Online or Compuserve need to know that they are seeing only those Internet sites pre-approved by their service provider.

Commercial online services are very useful, but represent the tip of the knowledge

iceberg. It is also critical for analysts to understand that commercial online services have different kinds of access and are not equivalent to one another. A CIA study found that of all the journals of interest to their analysts, one fifth were accessible through LEXIS-NEXIS (generally trade publications), one fifth through DIALOG (generally academic publications), one fifth through other online services (such as specialty scientific & technical publications), and *two fifths were not online* (such as Third World publications). Therefore, a collection strategy which mixes and integrates the different online services with hard-copy document acquisition is most likely to be successful.

Limited access electronic databases, such as are maintained by universities, industrial associations, or businesses, can over time be identified, and access gained through formal or informal contact. *Here again, overt human contacts are your best means of identifying pertinent databases that are not in the public domain but are accessible.*

Published literature and "grey literature " (limited edition publications) are the more commonly recognized mainstay of the open source world. *Do not overlook foreign language materials.* The *Burwell Directory of Information Brokers* will help the analyst identify professional searchers who speak a foreign language and are familiar with specific topics such as aerospace or nuclear proliferation.

Speeches and briefings are often overlooked as critical sources of "tip-off" on changes in policies and capabilities. In addition to LEXIS-NEXIS searches for media reports on such speeches, organizations such as The British Library carry conference *Proceedings*. Finally, direct interviews and sponsored external research complete the list.

2007. Collection Investment Strategies

Realistically, the analyst is largely dependent on classified information that reaches their desktop workstation or their desk in hard-copy, and on such open source information that reaches them through SAFE. The analyst is also constrained by security and procurement processes that limit their ability to directly access external open sources including overt human experts.

Over time, we can expect progress in developing more direct access options for the analyst. In the interim, analysts can engage in several collection investment strategies where they allocate their time as a means of optimizing open source contributions to the all-source product.

First, analysts--in their role as collection managers--should pay heed to the words of Mr. Paul Wallner, the first Open Source Coordinator (and a member of the DIA senior executive service), who says that "open source should be the source of first resort". By focusing first on what is available through open sources, analysts will more quickly come up to speed on both content and context.

Second, analysts--in their role as resource managers--must recognize that it takes time to develop new forms of access, and that when they identify promising open sources which can contribute to the all-source intelligence production process, they should document their findings and make a business case for allocating funds to maintain access to such sources. Generally such resource planning must occur a year in advance of funds being obligated.

One investment strategy--initially addressing only how an analyst spends their time but ultimately suggesting how dollars might be allocated--would have the analyst spend twenty percent of their time identifying and analyzing open source information. It is important to note that because of the broadness of the open source environment, and the facility with which open sources can be exploited, a 20% investment of time or dollars yields dividends in excess of the investment, on the order of 50% of better of the contribution to the all-source product.

OSINT is well-suited to be the foundation for classified collection management through its provision of encyclopedic and contextual knowledge. However, classified sources must be used, and the analyst must create an integrated all-source product.

2008. Windows of Opportunity

One of the interesting realities about scientific & technical intelligence which has been noticed by expert analysts over time is that often, critical information is published in open sources for a time before it is suddenly classified.

"Secrecy" is in reality an administrative classification of information. Analysts should be alert to precedent knowledge as a foundation for targeting classified capabilities against programs that have suddenly become classified. Censorship is in fact an excellent "tip-off" that a body of knowledge is now being exploited for military purposes.

Pre-publication opportunities for collecting knowledge directly from overt human sources are especially valuable, since "secrecy" tends to be imposed on written information rather than inherent knowledge. If an analyst cannot obtain approval for direct access to foreign scientists and observers, the analyst might consider developing an external research contract with key academics whose foreign travel and attendance at conferences can be funded. There will be significant regulatory guidance on what is permitted, and close coordination with established HUMINT agencies will be required, but the analyst can serve as a catalyst for targeting specific kinds of knowledge before it is published.

Pre-recognition of emerging knowledge areas is also a worthwhile analytical focus. Using citation analysis and bibliometric studies from such unique sources as the Institute for Scientific Information is a very good means of rapidly identifying clusters of knowledge experts and new trends in their relationships to one another. Bio-technology, for instance, could be anticipated by an analyst observing increased cross citations between biologists and computer scientists.

In the final analysis, *there is no substitute for peer contact*. Analysts must strive to identify, get to know, and interact professionally with their counterparts in the private sector, for these individuals are funded full-time by their institutions to follow the topic the analyst is interested in, and can often provide short-cuts and direct access to information that would otherwise take weeks or months to identify and exploit.

2009. Collection Management

There are a number of influences on how classified collection capabilities are actually managed, and analysts need to be aware of the relative priorities and the inevitable gaps in coverage.

Tier One and Tier Two targets (e.g. Russia, China, Germany) will generally receive solid coverage but occasionally require emphasis or follow-up. It is important to note that just because a target is receiving a Tier One or Tier Two priority, this does not mean that classified sources are providing comprehensive coverage. Open sources can provide invaluable additional information including contextual knowledge.

Tier Three and Tier Four targets (e.g. Somalia, Burundi, Haiti) will generally not receive in-depth coverage, and the analyst will have to be very specific about their requirements. It is possible to request a temporary increase in priority for an important "gap" in knowledge about the target. Open sources can be especially helpful in providing "tip-off" information and contextual information which will help the analyst make a case for a temporary increase in priority against a specific aspect of the target.

"Needs-driven" intelligence production, which is to say production that responds to direct requests from the intelligence consumer, is under scrutiny from Congressional staff because they are presuming that such requests are being communicated outside the existing priorities management system. Analysts need to exercise care and have the support of their managers when fulfilling "opportunity analysis" requests. Here, however, open sources will often provide a cheap and quick means of giving the consumer "good enough" intelligence without tasking classified capabilities.

Traditionally, consumers talk to analysts, analysts talk to collectors, and collectors talk to or examine sources. This is the "linear" paradigm for collection management. Increasingly, as open sources become more useful to intelligence consumers, and security obstacles are gradually eliminated, a new paradigm is utilized, the "diamond paradigm". This means that consumers, analysts, collectors, and open sources can and should talk directly to one another, as a means of improving communications, avoiding misunderstandings, and getting "real time" answers from the source to the consumer.

The bottom line for analysts in the open source world: the more overt human sources you can develop in your field of expertise, the more ACCESS you will have to useful OSINT.

2010. Four Major Consumer Groups

In developing their research plans and thinking about how to craft their all-source products, analysts can benefit from an understanding of the four major intelligence consumer groups, each of which has a different "level of analysis" interest.

At the strategic level, departmental consumers are concerned with strategic generalizations and with the plans & intentions of their counterpart leaders across the board, in all regions. For example, if an analyst were to examine all of the countries where the contingency employment of U.S. troops is likely in the next few years, they might find that all of the countries less one or two are characterized by very high temperatures and humidity. This is an important strategic generalization because it impacts on aviation capabilities by reducing the amount of lift and the range of aircraft. Departmental planners can thus benefit from understanding that their "average" aviation capability in most contingencies will be less is assumed by doctrine.

At the regional level, theater commanders and their staff need regional generalizations and detailed mobility studies. For example, very few operational staffs will focus on port clearances (the deepest ship draft), the location of the five fathom line (critical to naval gunfire support), or the distance of the Embassy from the five fathom line (which determines if CH-46's can get there and back without Forward Area Refueling Points). Analysts able to draw out such generalizations will be able to provide a regional intelligence model that is very useful. Most of this information is available from open sources.

At the tactical level, mission area specifics and demographic and cultural studies are helpful. Most of this information is available from open sources, and in the case of demographic and cultural information, is often available only from open sources.

At the technical level, in addition to mission area specifics, it is helpful to develop realistic assessments of the degree to which both friendly and enemy capabilities are supportable by their respective logistics and intelligence capabilities.

There is no "schoolbook" solution for how to shape an intelligence analysis product in relation to the likely consumer, but if analysts are sensitive to the "level of analysis" that their consumer requires, they can provide intelligence products which are more meaningful and which reduce the burden on the consumer to sift through products.

2011. Intelligence Production

Continuing our discussion of the "level of analysis", here we can see that open sources have a great deal to contribute to the all-source product at each level.

At the strategic level, much of the information about military sustainability, including the availability of fuel, water, and rations, can be obtained through analysis of open sources.

The analyst that understands history and geography can exploit open sources to establish a good sense of how geographic location and civil allies might influence plans and intentions.

At the operational level, open sources are not only vital, but often more pertinent than classified sources when studying military availability, geographic resources, and civil instability. Jane's Information Group is regularly credited by analysts with providing "tip-offs" on new weapons acquisitions. A sound understanding of geographic resources can help analysts interpret various scenarios, some of which may not be supportable (or may be driven by) a lack of resources such as oil. Civil instability is especially understandable through open sources. One Department of State analyst, studying the possibilities for instability in Iran in the event of the leader's death, found that clandestine sources tended to reflect the biases of the sources, all former officers under the Shah, and that local newspapers, despite censorship, were provided the most accurate sense of the situation. *Foreign language skill is essential to derive the fullest possible benefit from open sources.*

At the tactical level, while military reliability (troop training, equipment maintenance) is best established through classified sources, open sources offer a great deal. Here it is important to understand that organizations like Jane's Information Group have a great deal of information about military reliability that they do not publish, but which is available on demand. Geographic terrain, particularly for the bulk of the Third World for which the Defense Mapping Agency does not have data, can be studied through commercial imagery. Very few people in Washington realize that 10 meter commercial imagery is adequate for the production of 1:50,000 combat charts with contour lines, as well as simulated three-dimensional fly-bys. SPOT Image Corporation can provide these products for anywhere on earth within 24-72 hours.

Finally, at the technical level, open sources are especially useful in evaluating the civil infrastructure, including the telecommunications, power, and financial networks.

2012. Target Categories

Each area of operations is likely to have a mix of four different kinds of "warrior class" which must be studied. These distinctions are provided in order to help the analyst broaden their effort beyond standard order of battle information, and to emphasize the utility of open sources in understanding non-traditional capabilities.

The traditional opponent which the U.S. has prepared for is the "high-tech muscle" warrior, represented by most of the Western allies and such major powers as Russia and China. This also includes powers such as Iraq which have invested heavily in expensive and sophisticated mobility and weapons systems. Existing classified collection capabilities are best suited for studying this warrior class, as the military systems generally emit heat or have clearly recognizable electronic signatures.

The next most understood warrior class, the "low-tech muscle" warrior, is generally associated with low intensity conflict scenarios. This warrior class is very difficult to track using existing classified capabilities because it represents the "low slow singleton" problem. This class of warrior utilizes single human couriers, Cessnas, and unsophisticated means of communications which do not lend themselves to interception. Surprisingly, open sources turn out to be useful against this class of warrior. The best example of a "success story" is found in the Southern Operations Command, which worked with the Los Alamos National Laboratory to obtain, translate, and study Latin American newspaper articles about drug activities in Latin America. SOUTHCOM discovered that Latin American investigative journalists are very good and provided complex reporting on the relationships between drug cartel members, the supply routes, the arrival of precursor chemicals, and a wide variety of other useful information.

The least understood warrior class is the "low-tech brain" represented by Islamic fundamentalism, for example. This is a warrior class for which open sources are the only viable means of understanding its plans and intentions. However, the open source materials to be mastered are so voluminous, and almost always in a foreign language, so that this becomes a very labor-intensive activity. Against this kind of problem, overt human experts in the private sector often offer the shortest route to insights.

Finally, the "high-tech brain" warrior class, now very popular as we think about both information warfare and economic warfare....here open sources play a very important role. Examples include hackers, electronic bank robbers, and industrial spies.

2013. Types of Overt Human Sources

The purpose of this chapter is not to over-generalize or to categorize all human sources into four groups, but rather to stimulate analyst consideration of what biases and accesses might be represented by any particular overt human source whose written or verbal work they are integrating into the all-source product. These generalizations are offered for discussion purposes only!

These categorizations are drawn from a French source with a strong background in clandestine intelligence, who has spoken publicly on open source intelligence methods.

"Ivory Tower" academics, irrespective of their cultural backgrounds, tend to quote one another and to focus on abstract aspects of a problem in isolation from political and economic realities.

"Band-Wagon" journalists, always following the latest story, have a tendency to write about whatever the latest trend is, whatever the latest "spin" is on a story.

"Mainstream" operators are bound by their institutional or political loyalties to cite the conventional wisdom.

"Up and coming" leaders are the best source for tip-offs on emerging trends and plans and intentions, because they are change agents and more likely to put forth innovative and controversial ideas.

In evaluating the range of open sources that can be collected and integrated into an all-source product, the analyst might wish to consider each open source document with respect to the above four categories, and then to search for open source materials from those categories that are not yet represented. In this fashion, a "collage" of opinion can be charted which is more likely to offer insights, and to provide a solid context for the integration of classified intercepts and other classified materials.

2014. OSINT As A Resource Saver

Apart from its value as "content", as part of the all-source solution, open sources offer significant savings when they are used to avoid waste and unnecessary tasking of classified intelligence capabilities. It is sensible to avoid sending a spy where a schoolchild can go. It is also sensible to understand that intelligence products which limit themselves to classified sources are likely to miss important contextual knowledge and perhaps suffer from serious misperceptions.

Open sources can be the foundation for establishing a more efficient and more focused classified collection management plan. Open sources can be a means of satisfying intelligence consumers with "good enough" answers that avoid tasking classified systems at all. Open sources can be supportive of classified collection targeting, by helping the analyst identify specific human, communications, and organizational targets so that classified capabilities can be "pin-pointed".

Mr. Keith Hall, Director of the Community Management Staff, coined the term "ASK-INT" when he was a member of the professional staff of the Senate Select Committee on Intelligence. Too often, he noted, classified capabilities were tasked to obtain information that could be had for the price of a telephone call. Naturally there will be times when the analyst does not wish to reveal interest in a topic, but there are means for asking open source questions through contracted private sector parties at a lower cost than would be incurred when assigning the question to classified capabilities.

In the signals intelligence arena, open sources have proven to be extraordinarily useful in monitoring conditions across entire nations and in specific areas of interest such as the political and economic arena. For example, analysts tracking regional newspaper stories and editorials can form very accurate impressions about stability and changes in political power. Open sources also provide very valuable information about telecommunications networks (for example, the exact location and nature of power plants, telephone switching stations, and satellite downlinks) which can be used to target classified capabilities.

In the imagery arena, commercial imagery is now available at 10 meters resolution from SPOT Image Corporation, and 2 meter resolution from the Russians. A variety of other commercial imagery providers are emerging, some offering 1 meter resolution imagery capabilities. Low cost commercial imagery, and maps, are a very important resource saver.

2015. National Information Strategy

The national and defense intelligence communities are part of a much larger information continuum, discussed in Chapter 001. One of the challenges facing our Nation as it enters the Age of Information is that of fully exploiting open sources, and ensuring that the broadest possible range of open sources are available to the national and defense intelligence analyst.

The Defense Information Infrastructure (DII), the National Information Infrastructure (NII), and the Global Information Infrastructure (GII) are part of an innovative and comprehensive effort by the current administration to develop increased connectivity across all sectors of the information continuum.

As the Vice President of the United States of America has noted on many occasions, the NII seeks to "harness the distributed intelligence of the Nation". What this really means to the professional intelligence analyst is that new means are being developed which will allow the analyst to access distributed centers of excellence where overt human experts and unclassified electronic databases are maintained. This is helpful to the intelligence community because it enables exploitation of expertise that has been funded by the private sector.

Still lacking for the intelligence analyst is an inventory of such centers of excellence as they apply to the needs of the various functional area specialists. In the interim, each analyst must attempt to identify such centers on their own, and to then work with the library and other collection channels to develop regular access.

An opportunity exists for analysts to take the initiative in developing international unclassified burden-sharing agreements with their counterparts in allied intelligence agencies. Australia has unclassified information on the South Pacific, France and Italy on Africa, and so on. Creative exchanges of unclassified information could be helpful.

Finally, it is important to stress that the existing electronic infrastructure for accessing open source information is not secure. Analysts need to recognize that Internet transactions can be monitored, that viruses are rampant outside the TEMPEST environment afforded by the intelligence community, and that there are many security hazards, both in terms of monitoring and in terms of destructive software, in the open source world. A national information strategy will begin the process of making it safe to work in cyberspace.

2016. Optimizing OSINT

The purpose of intelligence is to inform the policy-maker and the commander.

In developing their collection management and intelligence production plans, the analyst should consider the following paraphrase from the Navy Wing Commander who led the lead flight over Baghdad during the Gulf War:

> *"If it is 80% accurate, on time, and I can share it, this is a lot more useful to me that a compendium of Top Secret CODEWORD information that is too much, too late, and needs a safe and three security officers to move it around the battlefield."*
>
> Navy Wing Commander
> Technology Initiatives Wargame 1992
> Naval War College, Newport RI

In striving to satisfy an ever-growing demand for intelligence, about an always expanding range of topics, the analyst will have to adopt the traditional public administration principle of "satisficing", working to provide the intelligence consumer with "good enough" intelligence. Just as "better" is the enemy of "good enough", excessive reliance on classified capabilities which are already over-tasked, can be counter-productive to the task of informing the intelligence consumer.

In the chaos of the 21st century, the distributed centers of excellence in the private sector which collect and process open source information, are the analyst's first line of defense--as Mr. Paul Wallner has noted, "the source of first resort".

Ultimately the all-source analyst is responsible for thinking in context and ensuring that the policy-maker and the commander receive the best possible intelligence product. Open sources are not a substitute for classified sources--they are a contextual and encyclopedic foundation for thinking about the problem. Open sources are the means by which the all-source analyst extracts the greatest possible return from classified sources.

In the Age of Information, "intelligence" is defined less by whether it is classified or unclassified, and more by whether it is on time, on target, and useful to the consumer.

Chapter 3

INTERNATIONAL OPEN SOURCES AND SERVICES

3001. Purpose of the Chapter

The purpose of this chapter is to provide an orientation to international open sources and services which are available to the all-source analyst. Although much of the open source world is not yet easily accessible to analysts because of security and procurement constraints, the Commission on Intelligence report of 1 March 1996 has defined such access as "critical", and recommended that dramatically improved analyst access to open sources be a top priority for the Director of Central Intelligence and a top priority for funding.

This orientation will discuss electronic access, the identification and acquisition of "grey literature", the identification and exploitation of international experts, and several examples of world-class international open source capabilities including Jane's Information Group and SPOT Image Corporation.

Appendix D provides a concise directory (including complete contact information) for all international open sources & services discussed in this chapter. There are many, many more international sources available to the analyst which can be readily identified either through traditional library research, or through direct contact with international experts who can tell the analyst what sources they have found most useful for specific topics. The References are good starting points for additional direction.

3002. American Online Services

Most people unfamiliar with the world of open sources think of America Online and COMPUSERVE when they think of "online services".

In fact, "real" commercial online services, the kinds used by professional information brokers and specialists world-wide to do serious research, are completely different in nature and operation.

LEXIS-NEXIS and DIALOG are the two premier U.S. commercial online services. They each offer, for specific subscription and access fees, a wide range of electronic libraries. Access can be as cheap as $20 for a quick search, or $70-100 an hour for a complex search. It is best to work with an expert searcher to save money.

It is very important to understand that these two services are complementary and that searching one of them by themselves will not produce the best possible online search results. In the early 1990's a survey was conducted of all analysts in the Central Intelligence Agency, and each was asked to list journals of importance to them. The survey found that one fifth of the journals were available through LEXIS-NEXIS, one fifth through DIALOG, one fifth in

CD-ROM or electronic form, and two fifths were not available online.

American online services, although they have shown significant improvement in the past few years, are still primarily a source of English-language materials from the mainstream of the Western hemisphere, and specifically the United States and the United Kingdom.

America Online and COMPUSERVE are the equivalent of the corner drugstore when compared to the far more robust and extensive holdings of LEXIS-NEXIS and DIALOG "libraries". They do, however, offer very fine interfaces to the world of newsgroups as available on the Internet, and they also offer a number of organized conferences (such as the Military Forum in COMPUSERVE). Most people think of these services, available for around $25 a month, as cheap, but in fact that is only the basic access cost--once the per hour online charges are added, those who spend a lot of time browsing can find themselves spending $200 a month. Direct access to the Internet, including free NEWSNET services, is available for $20 a month from numerous services such as UUNET, Capital Area Internet Services, and DIGEX.

3003. Foreign Online Services

The world of foreign online services is more complex, and for the analyst concerned with international matters, often more rewarding. Unfortunately, these services are not routinely available to the U.S. intelligence analyst today. They are, with the increased emphasis on open sources brought about by the Commission on Intelligence, likely to be made available if requested by the analysts. Their fees are comparable to US services.

The Derwent World Patents Index (DWPA) is the most comprehensive database of inventions published worldwide. Every week more than 20,000 patent documents from 40 countries are processed into patent families, that is, groupings of patent documents from different countries covering the same invention. Each record has an English language abstract, is fully indexed, and is online. Selected technical drawings are included in the online holdings. Generally comprehensive coverage of all technology dates from 1974.

Questel/Orbit is an international online service specializing in patent, trademark, scientific, chemical, business, and news information. It was the first company world-wide to provide access to patent drawings online. Its holdings include materials from the European Patent Office, Japan Patent Information Organization, and the U.S. Patent Office. This service also focuses on international trademarks, and on scientific & technical research, breakthroughs, and products.

STN International, standing for (the Scientific and Technical Information Network) is an online search service providing direct access to over 190 scientific, technical, business, and patent databases. STN is operated jointly by the Japan Information Center of Science and Technology in Asia, by FIZ-Karlsruhe in Germany, and by CAS in North America.

GaleNet is the new online service from one of the most prominent and reliable publishers of international directories such as the *Encyclopedia of Associations*, the *Guide to Internet Databases*, the *Gale Directory of Databases*, and the *Research Centers and Services Directory*.

International Thomson Publishing does not offer its basic references online, but it does offer a free online search service which is useful, allowing simple searches by author, title, or other user-defined search criteria. Among the titles they publish are *Geographic Information Systems: A Guide to the Technology* (1991).

3004. Information Brokers

What is an information broker? The short answer is: the information broker is and can be an analyst's best friend. This is an individual who specializes in discovering, evaluating, and distilling information available from public sources, in order to answer a specific question from a customer. They generally charge between $70 and $120 an hour inclusive of search fees (they are expert at keeping the online cost down, but their offline expertise is valuable), plus between $15 and $60 for individual document delivery. Generally online searches identify the existence of specific documents, which must then be located in a library, copied, and faxed to the buyer.

Perhaps most importantly to the analyst, information brokers tend to specialize in specific scientific and technical, or industrial areas, and so over time they build up an in-depth knowledge of open sources and methods which can be of invaluable assistance to the analyst working a short-fused problem set. This is important: a good information broker can save the analysts days if not weeks of preliminary research.

The *Burwell World Directory of Information Brokers* is available in both hard and soft copy, and is indexed by subject matter as well as by foreign language expertise. Ordering information is provided in the hand-out.

Information brokers differ from all-source analysts in two important ways:

First, they specialize in discovering, evaluating, and distilling information for a client, but they do not conduct the kind of analysis and estimative forecasting that a typical intelligence community analyst is expected to perform; and

Second, they deal only with unclassified public sources which are legally and ethically available.

Having said that, there is much that analysts can learn from information brokers. Two books, for which complete ordering information is provided in Appendix D, are especially recommended:

Reva Basch, *Secrets of the Super Searchers: The Accumulated Wisdom of 23 of the World's Top Online Searchers*; and

Sue Rugge and Alfred Glossbrenner, *The Information Broker's Handbook*.

3005. Grey Literature

A major obstacle to U.S. understanding of foreign events, foreign cultures, and foreign plans and intentions is the fact that most of what is published about these foreign targets is in a foreign language and generally published in limited editions which are not readily identifiable, translatable, and reportable by existing U.S. intelligence capabilities.

"Grey Literature" is a growing field of interest, as experts worldwide begin to focus on the importance of "niche" information. Because grey literature is not "mainstream" and is often not electronic, the challenge of identifying and obtaining just the right piece of information requires the employment of expert intermediaries.

Examples of grey literature include trade show information, conference proceedings, unpublished "pre-prints" or works in progress, local area telephone directories, university yearbooks, and mailing lists for specific industries or countries.

Information brokers remain one of the best paths to grey literature because these information brokers specialize in selected areas and by virtue of their constant focus, are aware of new publications as they emerge, and are also in contact with key people in foreign industries and governments who can help them obtain selected materials not on the public market but still legally available in limited numbers. The *Burwell World Directory of Information Brokers* is unique for having an index identifying individual brokers based on their foreign language, foreign database, and foreign residence knowledge.

Professional associations, including U.S. associations, are a very rich source of leads and often will provide original source materials at no cost. At a minimum, professional associations can help analysts quickly identify authoritative individuals in specific countries who can be approached with a question or request.

Finally, international experts who are not information brokers and may not be associated with any professional association, are key players in linking analysts to exactly the right information. Two means of identifying such experts will be discussed momentarily.

3006. Document Acquisition

Before looking at international experts, it is useful to examine several services which specialize in document acquisition. The most prominent of these, with offices world-wide, is FIND/SVP, where SVP stands for the French-language phrase "if you please". FIND/SVP

has a major office in New York, and operates both a "quick find" service that will locate two or three relevant articles upon telephone request, and a more in-depth strategic research arm.

CISTI is the Canada Institute for Scientific and Technical Information; it provides world-wide scientific, technical, and medical information services, and also provides at no cost online, the CISTI Online Catalogue. One of the special features of CISTI is its collection of conference proceedings and serial reports.

Disclosure, Inc. has teamed up with American Business Information to provide access to high quality mailing lists and company financial and credit reports. Although publicly traded companies have the most information available, privately owned companies also have financial statements and credit reports, and primary research through industry experts (such as the editors of trade newsletters) can uncover more information. They also have a world-wide presence and can respond to document acquisition requests in their area of expertise.

Genuine Article is the document delivery service offered by the Institute of Scientific Information, which is unique for having a global citation analysis database in both science and social science. Citation analysis is a uniquely valuable analytical tool. The references tell the analyst who has cited or is cited by any major article in academic, scientific & technical, and international business literature. This allows the analyst to determine several things: taking a known relevant work, to determine who has done the latest work in this area, identifying them through their citation of the relevant work; taking a known author, rapidly establish the author's peer standing and influence through citations by others; or taking a specific area of inquiry, quickly cluster the different expert groups through their citations of one another.

Uncover Reveal is an online periodical article delivery service and a current awareness alerting service. It indexes nearly 17,000 English language periodicals in its database. There is no charge for searching the database; articles ordered can be delivered by fax, often within one hour.

3007. International Experts I

Analysts forced to rely on "umbrella" support contracts with a few specific intelligence industrial base companies will often find that these companies are simply one bureaucracy removed from the government, and do not have the flexible access to international experts that is needed.

One solution for analysts is to use in-house access to commercial online services such as LEXIS-NEXIS and DIALOG, to identify international experts.

In two different exercises, one on Somalia for the Marine Corps and one on Burundi for the Commission on Intelligence, LEXIS-NEXIS proved superb at identifying the top twenty-five journalists whose by-lines suggested they were expert on the country on which

they were reporting. Such individuals could be easily contacted for background information and insights on emerging trends. It is worth noting that journalists publish less than ten percent of what they know, and often have an understanding of personalities and motivations that they can share off-line but could never publish.

At the same time, using commercial online sources to search for quoted experts is a fast means of locating key individuals whose expertise has already been evaluated and is now relied on by journalists. Their knowledge will be different from that of the journalists.

Finally, since both LEXIS-NEXIS and DIALOG carry the transcripts of Cable News Network and other major international broadcast media such as the British Broadcasting Network, it is also possible to identify the "world-class" experts that are routinely called upon to comment on air.

3008. International Experts II

A second and deeper means of identifying experts is to work through the capabilities provided by the Institute of Scientific Information, and its unique proprietary publications and databases.

Both the *Social Science Citation Index* and the *Science Citation Index* were created to perform a unique service which is not available from any other source: they identify who has cited whom up to date (generally up to within three months). This allows an analyst to take a known work that is directly pertinent, and by examining who has quoted that work, to quickly identify those who are publishing in the field today.

Perhaps even more importantly, the Institute of Scientific Information is able to perform bibliometric analysis on all of this data, and cluster papers according to their influence. "Bibliometric" refers to the study of citation patterns and their meaning, rather than to content analysis. In effect, individual papers can be evaluated based on the degree to which they were considered relevant by others, and at the same time the relationships between different authors and schools of knowledge can be plotted using clustering techniques.

Finally, complete addresses and contact information are available for each author, enabling an analyst to quickly establish direct contact with an individual whose publications and peer citation establishes them as a high-value subject matter expert.

3009. International Directories

There are many international directories, but a few stand out. Ordering information for all of these are contained in Appendix D.

The *Encyclopedia of Associations* is a unique tool for it identifies key professionals in

every scientific and technical endeavor, and often permits direct contact with individuals who would otherwise be constrained by corporate non-disclosure terms.

The *Worldwide Directory of Government Officials*, updated frequently, is a comprehensive source for complete names, titles, telephone numbers, and even fax numbers for government officials from defense, intelligence, and all other government departments.

The *Research Centers Directory* and the *Directory of Publications and Broadcast Media* are examples of useful tools for getting in touch with key people.

A number of excellent references, all listed in the hand-out, are published by The Reference Press, Inc., and these include directories of key contacts in the various geographical regions of the world.

Finally, the International Supplement to The National Directory of Addresses and Telephone Numbers.

It merits comment that even without any directories at all, an analyst willing to use directory assistance, including international directory assistance, should ,in the space of four telephone calls, be able to identify somebody with knowledge useful to the problem at hand. An example: an analyst interested in environmental conditions in an area not covered by any directory, could call directory assistance in that country, ask for any listing beginning with the word "environment" in the local language, and within four telephone calls probably identify someone who is moderately familiar with exactly the information desired.

The bottom line: if you are persistent, the telephone really can help you reach out and touch someone.

3010. Jane's Information Group

Jane's Information Group has long been a primary source for many military intelligence analysts. In his thesis on *Open Source Intelligence: An Examination of Its Exploitation in the Defense Intelligence Community*, then Major (now LtCol) Robert M. Simmons found that many analysts relied on Jane's for tip-offs about new weapons developments and technology transfers.

Among the more obvious benefits from Jane's Information Group are its widely admired publications, *International Defense Review*, *Jane's Intelligence Review*, and of course its entire series of handbooks on different weapons and mobility systems, now available in both hard and soft copy, including a CD-ROM version with illustrations.

Less well known, but still popular, are the Sentinel Country Series, which very few people realize is based on the original analysis model developed by the Marine Corps Intelligence Activity in association with Marine Corps warfighters, and provided to Jane's as

an incentive to meet the demand for an unclassified country study. Jane's also publishes a series of extremely detailed reports on defense budgets world-wide.

Not-so-obvious capabilities which every analyst needs to understand are the following:

First, under special arrangements, the full range of information available through Jane's can be obtained online; this can include information on training and maintenance which has not been published and will not be published.

Second, Jane's can undertake special studies on demand, and utilize its special access as well as its in-house store of knowledge to produce useful "proprietary" reports which can serve as the foundation for follow-on all-source studies.

Finally, Jane's has a global network of experts who have spent years studying specific countries and are intimately familiar with specific defense personalities including field commanders. Under appropriate conditions, analysts can arrange to be put in touch with the pertinent Jane's expert, who can then become the analyst's "running buddy" for a specific analysis project.

3011. Oxford Analytica

Oxford Analytica, whose complete range of products is now available to the analyst through the Open Source Information System (OSIS), is believed by many to be the world's best private intelligence agency in the purest sense of the word.

Founded by an American, Dr. David Young, Oxford Analytica was inspired by Dr. Young's experience as the private secretary to Dr. Henry Kissinger when both served on the National Security Staff under President Richard Nixon.

The organization combines a fifteen person "watch team" which is organized by region and reads all the wires each day, with the Dons of Oxford who are rotated through a morning meeting each day, always asking three questions:

-- What's right in the news that needs to be expanded for our clients?

-- What's wrong in the news that needs to be correct for our clients?

-- What "weak signals" are emerging which require a forecast for our clients?

Upon concluding that a special report is required, Oxford Analytica then commissions either a resident Don from Oxford, or one of over 1,000 experts world-wide. In most cases, the experts have direct access to key decision makers and can obtain authoritative insights through a telephone call.

The final unique element of the Oxford Analytica program, strongly influenced by Dr. Young's experience in serving the President of the United States, is that no report is allowed to be over two pages long, and all reports are required to be complete within four hours of commission--as Oxford Analytica is proud of noting, their material is tailored "for Presidents, Prime Ministers, and you".

3012. Eastview Publications

Eastview Publications, a popular provider of services to the Foreign Broadcast Information Service, is representative of the kinds of niche providers that have emerged with the "information explosion" and the opening of formerly denied areas.

It is the foremost provider to the world of military maps from the former Soviet Union, and distinguished itself during the Commission on Intelligence benchmark exercise on open sources by providing, overnight, a listing of all Soviet maps available for Burundi--maps that did not exist in the U.S. inventory and could not have been created by the U.S. for days if not weeks.

Eastview Publications is also a premier source for Russian grey literature, and through its office in Moscow is able to respond to a wide variety of requirements.

Another example of private sector capabilities focused on Russia and Eastern Europe is that of Access International, based in Albuquerque, New Mexico. This organization, managed by Ms. Marjorie Hlava, a distinguished leader of many key U.S. information associations including the American Society for Information Science and the Association of Independent Information Professionals, produces a CD-ROM in both Russian and English on major Russian information sources including legal and technical sources.

In the scientific and technical arena, Information International Associates, closely associated with the Department of Energy Laboratories, the Defense Technical Information Center, and the National Technical Information Service, is one of the best access intermediaries for international information. Ms. Bonnie Carroll, its President, has been a leader in professional organizations such as the National Federation of Indexing and Abstracting Services and others.

The above are only a small sampling of the kinds of capabilities that can help the analyst exploit international sources. Many others exist--for instance, *THIRD WORLD RESOURCES* is a quarterly review of resources from and about the Third World. Ordering information is contained in the hand-out.

3013. SPOT Image Corporation

During the Gulf War, it took just over sixty days to collect the mapping, charting, & geodesy data that was required for both the targeting of precision munitions, and the creation

of 1:50,000 combat charts with contour lines. As U.S. forces are confronted with a variety of contingencies in the Third World--in areas which have not traditionally been high on the U.S. intelligence collection priority list--they are finding that the lack of maps is a critical encyclopedic intelligence shortfall.

Fortunately, the private sector is in a position to make a major contribution in this area. Ten meter imagery from the SPOT Image Corporation, for instance, can be both multi-spectral and panchromatic, and is suitable for creating both 1:50,000 combat charts with contour lines, and three-dimensional mission rehearsal programs. The Air Force also finds it adequate for the targeting of precision munitions.

What SPOT imagery cannot do is provide the "ground truth" precision points needed to ensure accuracy for combined arms operations, and especially for the coordination of artillery and air strikes. This precision is now provided by the National Reconnaissance Office, and can also be provided by human assets on the ground with Global Positioning Satellite Receivers--each SPOT image requires roughly eight precision points (e.g. a precise location for an intersection visible from space), and each country had from 60 to 200 wide area images which comprise its coverage.

The Defense Mapping Agency has made great strides in the past few years in recognizing the value of commercial imagery, and is now in a position to integrate 5 and 10 meter commercial imagery for broad areas, 1 meter imagery for urban detail, and NRO or GPS precision points.

It merits comment that SPOT imagery is the source for project EAGLE VISION, which combine real-time downlinks from SPOT satellites with mission rehearsal software. This project, sponsored by the Air Force Chief of Staff, was used in Aviano, Italy to prepare air crews for flights to Bosnia, and was credited with doubling sortie effectiveness. Commercial imagery is low-cost in comparison to national imagery. in large part because it has a much lower resolution (10 meters versus under 1 meter) and in part because it does not have the security costs associated with national imagery. A normal procurement for a wide area is on the order of $3,000 to $5,000; individual "snap-shots" can be had for as low as $450, and SPOT advertises sales of imagery at $1.50 a square mile.

3014. Universities

Universities, both U.S. and international, comprise a "virtual intelligence community" of great value to the intelligence analyst. Among their unique features are the fact that they focus exclusively on knowledge collection and processing, and that they do so at the expense of someone other than the U.S. taxpayer. University faculty, university student bodies, and university databases are all available to the intelligence analyst at either no cost, or at the nominal cost associated with access to an existing system.

Here are four examples of exceptional facilities of direct utility to intelligence analysts; contact information for each of them is provided in the hand-out:

-- Monterey Institute of International Studies. They have created and they continue to maintain a database on the proliferation of nuclear weapons, utilizing graduate students with native fluency in Russian, Chinese, Korean, Vietnamese, and other languages. They capability is so extraordinary that they have become the foundation for all-source enhancements within the Nonproliferation Center.

-- Mercyhurst College. This small college in Erie, Pennsylvania is unique because it offers the only program in the United States which grants an undergraduate degree in intelligence and research analysis. Founded and managed by Mr. Robert Heibel, a thirty-year veteran of the Federal Bureau of Investigation, this program requires its students to produce regular newsletters, relying only on open sources, about international narcotics, transnational crime, and other key issues. Students in this program are in very high demand as interns throughout the intelligence community.

-- University of Michigan. They operate a "clearinghouse for subject-oriented Internet resources", including resources for aerospace engineering and government sources of business and economic information.

-- Rice University. They operate an Economic Bulletin Board Service which provides a number of useful files including press releases from the U.S. Trade Representative, defense conversion information, East European trade leads, and so on.

3015. Knowledge Age

Knowledge Age, an intended pun, is intended to highlight the fact that knowledge gets old quickly, and to sensitize the analyst to the fact that there are degrees of currency in knowledge which can be very important.

Books are generally ten years old by the time they are published, and many of them started as graduate theses. Magazine articles were generally commissioned and researched ten months before being published. Even newspaper articles, all but the most sensational, were directed by editors and researched by reported up to ten days before publication. On the Internet, where time moves quickly, clips may be ten hours old.

The point here is that knowledge which has been published is old knowledge.

Where the analyst can get ahead of the curve, and develop insights not yet available to the general public, is by going after unpublished knowledge. By identifying and getting in touch with international experts, the analyst creates the opportunity to ask for tailored new knowledge which is based on unpublished "works in progress".

The analyst should also become sensitive to the existence of "barter networks", and knowledge networks, in which the elite in a particular area of inquiry routinely exchanges insights and information months if not years before publishing. The goal of the analyst should be to establish themselves as a member of this elite, and to use their own unclassified knowledge and their access to unique unclassified information collected at government expense, as their "membership fee" into this broader network of international experts who comprise the analyst's de facto "virtual intelligence community".

3016. Conclusion

There are no hard figures, and in any case the figures will vary from subject to subject and crisis to crisis, but informed judgement is fairly consistent on this point: 80% of what the analyst should know, in the ideal, is not in the USA, is not in English, and is not in electronic form.

The leveraging of international sources is essential for the analyst intent of obtaining a fresh perspective and good "tip-off" value. International open sources and services should be the foundation for a strong all-source analysis program.

Chapter 4

THE INTERNET AS A TOOL FOR ALL-SOURCE ANALYSIS

4001. Purpose of the Chapter

The purpose of this chapter, developed by Dr. Ross Stapleton-Grey, a former civilian intelligence analyst widely known for his Internet skills, is to present a very broad overview of the global capability known as "The Internet" or "the Net".

The Internet is a global communications medium that permits extraordinary flexibility in communicating with a wide variety of people from all walks of life, in receiving free information from many sources, some of dubious authenticity, and in obtaining access to distributed databases, many multi-media in nature, all over the world.

This chapter will discuss in general terms the utility of the Internet to the all-source analyst, with special attention to the use of electronic mail, newsgroups, lists, and conferencing systems.

We will discuss some of the dangers of the Internet, including the problems of noise and flame wars, as well as the almost total lack of privacy and discretion.

The last half of the chapter will focus on the most productive element of the Internet, the World Wide Web, and will provide five practical examples of how to exploit the Internet in support of the all-source analysis endeavor.

The Internet is a work in progress--it is changing every day at an astonishing rate. Some have characterized it as "the Library of Congress with all the books on the floor". It has its uses, but using it also has its limitations.

This course includes five hand-outs intended to facilitate self-study and hands-on exploration of the Internet's utility as one of the sources for information in support of the all-source analysis endeavor, as well as a source of continuing professional education for the intelligence analyst.

4002. Introduction: What Is the Internet?

The Internet is a "network of networks" based on standard protocols which have been established by common consensus among international experts. It is unique in that it is not controlled by any governmental body, and is a relatively autonomous, almost anarchistic, system that works because of its common standards.

It began in the 1970's as a Defense Advanced Research Projects Agency (DARPA) testbed to meet Department of Defense research needs and to develop internetworking

technology. It was divested in 1986 to other agencies in the U.S. government, notably the National Science Foundation, with participation from the Department of Energy and the National Aeronautics and Space Administration. The National Science Foundation initially funded regional and national back-bone service providers, and then switched its funding support to end users--this led to the development of commercial service providers. In 1994 U.S. government funding for the Internet ended.

Internet protocols (the standards which allow any computer to join "the Net" from anywhere in the world)won the competition as a general-purpose technology for constructing networks. It's not the most elegant system, and the Internet has a great many faults that other networking schemes avoid (it is still missing a lot of security features), but it is an open protocol, that is, the standards were developed in an open forum. It is now part of every commercial on-line service and computer company's planning because it has become the world's general-purpose digital information carrier.

Most people think of the Internet as a large electronic mail environment. This is its most common use. However, from an analysis point of view it is much more important in its capacity as a global network of distributed databases maintained at the expense of different universities, companies, and individuals. The Internet is an electronic library, with many public spaces and some private spaces.

Commercial services now include data maintenance, data discovery, and--the foundation for future exchanges of content--digital cash. Today, in the absence of wide spread digital cash capabilities, the Internet is largely a direct marketing network, but in the near future it could become the primary vehicle for organizing the exchange of goods and services. The Internet Society is a non profit activity that coordinates Internet standards, but it does not "control" the Internet.

4013. Where Are We Today?

The Internet is evolving from an academic luxury to a commercial necessity. Today, although the exact numbers are in dispute, we see at least 30 million individual users and over 40 thousand host networks which can be accessed via the Internet.

The Internet continues to grow at geometric rates. Local Internet access providers are finding that they can barely keep up with demand and service is often poor because of the speed with which large numbers of customers sign up daily.

The Internet was fairly closed to users outside government and the universities for much of its history. Big changes occurred when the National Science Foundation (NSF) took steps to turn it from an experimental, research effort, to a commercialized service. The NSF stopped funding networks, and started providing end users (such as schools) with funding to buy network services, establishing the first competitive markets for Internet services. Growth has been enormous ever since the NSF established regional networks (such as SURANET in

the Washington D.C. area) and especially since most of the restrictions (such as NSF's "Acceptable Use Policy" for its networks that required traffic be noncommercial research and academic in nature) were removed.

Today over 50% of the Internet sites are commercial in nature, with research organizations including universities comprising another 29%.

There is less "content" than one might expect. One authority, Dr. Joseph Markowitz, Director of the Community Open Source Program Office, notes in his primary briefing on open sources that "content" comprises just one percent of the Internet, with electronic mail, advertising, and other uses occupying 99% of that capability.

"The Internet is like the Library of Congress,
but with all the books strewn randomly on the floor."

This popular quotation, in several variations, has been around for years, but no one, including Dr. Vint Cerf, founder of the Internet and most recent President of The Internet Society, knows just who first thought of the analogy--but it is a good one!

4004. How Representative Is the Internet?

There are three ways to understand the character of the Internet.

In global political terms, it is dominated by the United States of America, which has more users, more hosts, and more bandwidth than the rest of the world taken together. Western Europe is a very weak second to the USA. The major online service providers, American OnLine and Compuserve, are U.S. companies with a global membership.

In most countries, only a relatively small number of prominent scientists or wealthy users are able to access the Internet, and many of them are restricted by local telecommunications limitations to a very low baud rate and a short access time. This represents the technical character of the Internet. In much of Africa, Asia, and Latin America, for instance, technical constraints are severe.

The Internet became a popular phenomenon around 1994, and exploded on the commercial markets in 1995. Online services all established connections to the Internet, so many of those users can be considered to be "on the Internet." However, it is very important for online service customers, such as those using America Online and Compuserve, to understand that the access they receive to the Internet from these services may be constrained-- Internet search tools such as Web Crawler will "see" only those Internet sites that have been registered by the managers of the online services. Analysts using the Internet need to understand what "hidden limits" might be placed on their searches and the search results by such constraints.

Examining the Internet at a personal level, the overwhelming majority of users around the globe, i.e. factoring in all countries, is comprised of research scientists. Within the USA, on the other hand, the largest group is individuals for whom the convenience and low cost of electronic mail and conferencing has become a major attraction. A third kind of user, the organizational user, is being provided with Internet access as a means of reducing organizational communications costs and increasing informal coordination among members of the organization.

4005. Lists: Versatile Low-Tech Tools

Electronic mail is the single most familiar tool on the Internet. Distribution lists are a first step beyond simple point-to-point E-mail. Analysts can quickly create their own individual "broadcast" groups that permit them to share information or ask questions of their counterparts world-wide.

Automated Lists, known as "Listservs" can be moderated or open. Such lists maintain a constantly changing directory of interested parties, and re-broadcast any messages sent to them to all current members of the list. Membership can be restricted, or open

Electronic mail is the lowest common denominator, since it can be used from virtually any platform (including dumb terminals) and doesn't need to be real-time. Usually one or more individuals interested in an issue or topic will create a distribution list as their set of correspondents grows beyond a few dozen. Some mailing lists may have thousands of subscribers.

Three examples of listservs of interest to the all source analyst are the Open Source List, maintained by the U.S. Army's 434th Military Intelligence Detachment (Strategic); the C4I List maintained by the Naval Postgraduate School, and the Information Warfare List, maintained by Dr. Fred Cohen, an international authority on information warfare who has served as a principal investigator for many defense and intelligence projects. Information on subscribing to all three lists is provided in Appendix E-2.

If you cannot find a list that meets your needs, consider starting your own--you could create one within the classified environment, and another within the open source environment. If you do not wish to be burdened with the maintenance, consider contracting this task out to a related center of excellence, such as a university with a strong program in your regional or functional area of interest.

A complete discussion of listservs and how to find and use them is provided as Appendix E-4.

4006. USENET and Its Newsgroups

USENET is a collection of thousands of newsgroups. Newsgroups are much like

E-mail distribution lists, focused on specific topics and with an emphasis on current events. Internet hosts pass each other USENET "feeds". USENET is not be confused with the larger Internet, something which happens frequently among new users.

USENET newsgroups are similar to bulletin boards, but require special newsreader programs to access the material. Instead of having mail arrive in the user's mailbox, the user accesses postings being held on a server, which is something like using a bulletin board system over a network.

Analysts contracting for an online service should note that in those instances where the basic membership only covers a few hours a month, and there are additional charges for any more time on line, it can become very expensive to do news reading online. One simple way to reduce costs is to utilize the "capture" feature in the communications software, and set for screen scrolling when entering the news area. This will allow for off-line reading as well as cutting and printing, and reduce online time to a minimum.

Here are three examples of pertinent newsgroups; a listing of typical headlines from each is contained at the end of Appendix E-1:

<soc.culture.kuwait>
<alt.current-events.bosnia>
<alt.politics.org.us>

Newsreader programs are generally provided by the same service through which you obtain access to the internet. They are all generally similar.

4007. Conferencing Systems

Conferencing systems are organized discussions, and are hosted on a server or servers which allow authorized participants, those who have password access to the system, to create conferences and within conferences, topics. All other users then have the option of reading entries, contributing their own entries, or "forgetting" the conference or topic by marking it as not being of interest.

Both Compuserve and America Online can be thought of as conferencing systems that "grew up;" when they first began members could only exchange information with other members, using both E-mail and public postings. As the Internet began to become an attractive resource, there was a great deal of pressure on the online systems to tie their services to the Internet, or risk loss of their members to ones that did. Some of the conferencing systems police their content, as Prodigy (to ensure that it's "family friendly") and America Online (which calls its rules its "terms of service") do. The online services do face some policy dilemmas, though: the Stratton Oakmont legal case ruled that because Prodigy censored some members' postings they could be held liable for not censoring libelous postings.

An examples of a Compuserve conference of possible interest is the Military Forum, which you reach--if you are a Compuserve subscriber, by typing "GO MILFORUM". Compuserve provides a number of other services of possible interest to analysts, including "GO MAGELLAN", where maps of current hot spots are available in GIF format, free, and other maps are available for a fee; "GO MAGDB", a large collection of journal articles; and "GO ENS", where ENS stands for Executive News Service, and permits you to establish a profile that selects articles of interest for your personal mailbox.

In the Whole Earth Electronic Link, possibly the most well-known and respected conference system ever built, topics 268 and 288 in the Whole Earth Review conference focus on open sources of intelligence and the reinvention of intelligence. Like most conference systems, monthly subscription fees are required to gain access.

4008. CAUTION: Some Problem Areas

Lists, newsgroups or conferences are contributed to and seen by hundreds to hundreds of thousands. The "noise to signal ratio" on the Internet is very high. If one subscribes to too many lists, or becomes too well known, they can be flooded with information. Although there are some sophisticated tools available today to help filter incoming information, one crude technique is to maintain several electronic identities, including an "unlisted" identity for personal friends. Another technique is to file everything. and then search for specific items of interest within this more limited (but still large) pool of information.

Another problem on the Net is that of "flames" and "flamers". Information on lists, USENET, conferences comes from broad communities of individuals. Although closely moderated lists may produce a high ratio of "wheat" to "chaff", many unmoderated discussions collapse under the weight of a few disruptive sources. "Flame wars" (harassing postings, name calling, and generally disruptive noise) are also common. Some contentious political and ethical discussions (such as on abortion, religion, race, etc.) are guaranteed "flame" generators. Analysts examining newsgroups and posting pertaining to the Middle East or the Balkan region are likely to find diverse and strong opinions, and have some difficulty sorting usable information from personal opinion.

It is important to understand that virtually anyone could be posting the materials found on the Internet, and that it will often be hard to ascertain the credibility of the source. Tools exist to explore "who is" a particular poster, and very good biographical information can often be obtained--as provided by the source themself.

Search tools and online services have their own limitations. Some Web search tools are best for thoroughness, others for new material, others for finding related information that does not have the actual key words. Searching the Net through an online service rather than a direct access provider will severely limit your results because online service providers impose censorship and access restrictions.

Everything about the Net is open for scrutiny by anonymous lurkers who can watch everything you post without revealing their presence, and in some cases arrange (illegally, or by abusing their authorized access as service providers) to monitor your private electronic mail. Internet users need to understand that there really is no such thing as private mail--an electronic message is forever, and might be seen by anyone!

4009. How On-Line Communities Form

It only takes two people to form an online community and share information. Word of mouth and existing personal relationships can quickly expand such communities. The practice of forwarding electronic mail to others is a very low-cost way of sharing information, and leads to widening communities. Broadcasting messages to lists of known interested parties also strengthens communities.

Users with common interests join (or create) lists and newsgroups. Their public postings are advertisements for communication, and users respond to each others' postings. Lists can be attract participants with very specific interests, e.g., C4I.

"Face to Face" communications are an essential aspect of online credibility and sustainability. At some point individuals will want to meet professionally, and this may strengthen or weaken the willingness to invest time online.

Given the face to face rapport, however, and a desire to share information, online communications quickly proves to be better than voice (you can send and forget electronic mail or have it cheaply translated enroute), it is cheaper than voice, and it provided an automatic record of exchanges.

Whether or not a professional and official email address is provided to the analyst, a personal email address through a commercial service provider is a good investment, both for personal communications with relatives and friends who are increasingly turning to the Internet as a primary communications channel, and for professional browsing in the open source world, where a great deal of information can be legally and ethically examined and downloaded without revealing your interest or your organizational affiliation. Analysts must ensure they follow approved procedures when integrating open source digital information into their all-source digital environment. The easiest and safest means is to keep external open source material in printed form, and to scan or keyboard pertinent passages. The alternative is to provide a diskette or send an electronic file to the authorized security point of transfer. Do not take chances with open source digital data!

4010. On-Line Communities, Virtual Contacts

The Internet community has literally exploded in the 1990's, and one can quickly find an online community for just about any topic. Not only are there

many, many pre-existing communities, but the conferencing systems spawn new ad hoc communities every day to deal with current events.

Such communities are a first step in identifying experts who can then be cultivated directly through "off line" personal electronic mail or more formal communications. An analyst can quickly build a "short list" of key people whose commentary can be observed and evaluated from a distance, as a "lurker", before ever introducing one's self. Networking informal sources to get a "head start" on an analysis issue is one of the best possible uses of the Internet. Remember, these communities of experts have spent decades of cumulative time becoming expert in specific areas, and they are usually going to be more familiar than the analyst with other experts and open sources of information about the topic or issue. They can provide a "first cut" that might otherwise take weeks of expensive library research.

There is an Internet culture, and there are standards of behavior. Although, as the New Yorker cartoon of two dogs dramatizes, "on the Internet, no one knows you are a dog", in fact first impressions matter and people will quickly form an opinion as to whether you are abusing their time, contributing to the discussion, or being stupid. Building trust on the Net takes patience, maturity, and a willingness to make constructive contributions to whatever discussions are important to you.

The Internet is today largely a barter or gift economy. At one meeting of international hackers, it was generally agreed that for every piece of information they each contributed to the Net, they generally got 100 pieces back, of which 10 were useful--hence a 10 to 1 noise ratio, but also a 10 to 1 return on investment.

Analysts who are cruising the Internet for information need to be aware of and comply with whatever official constraints may apply. If in doubt, don't post--just lurk and download, use the Internet as a cheap background briefing. The analyst also has the option of using the Internet, together with other traditional research tools such as the *Social Science Citation Index* and the *Science Citation Index* published by the Institute for Scientific Information, to identify possible direct contacts for official approval.

4011. Structuring Knowledge: Tools and Trends

Gopher was the first, popular tool for moving beyond lists and searching for information. The command, used at the prompt with the name of the site which must be known in advance, allows the analyst to access embedded menus and to select items to be downloaded. The Veronica search engine was created to search across a multitude of poorly documented Gopher sites. As gopher sites are now almost extinct, this is mentioned primarily as background.

WAIS was, until the World Wide Web, developed, the Rolls Royce of search engines, and for the first time provided a reliable means of both weighing the relevance of the found

files, and also of refining searches by commanding it to look for other documents "like" documents already in hand and found to be valuable.

Today, the two most popular tools are Netscape and the Web-Crawler. However, tools for the Internet are literally "exploding". Besides WebBrowser and the Microsoft Internet Explorer, the most impressive new tool, not yet widely used by the average individual, is Alta Vista, from Digital Equipment Corporation. Where the four programs return between 20 to 2000 "hits" on the name "Bill Gates", Alta Vista powers through the entire Internet and identifies 80,000 hits! Directions for using each of the above programs are found in the first student hand-out, together with other useful information for exploring the Web. Two of the hand-outs list specific sites of value to the intelligence analyst.

The Internet has always had an information organization problem, since very few people have ever been paid to create catalogs or indexes, there are few standards for online citations, and a great many documents and resources have just been dumped onto Internet sites with little regard for documenting their origin, validity, or even date of creation (much less expiration). Although commercial providers can be expected to offer value-added discovery and discrimination tools of increasing sophistication, it is difficult today to replicate a search, and most experienced navigators find that their best aid is a logbook in which they keep meticulous track of their wanderings in cyberspace. "Bookmarks" are citations of Web sites that a user can save, allowing them to find their way back later--the bookmarks are saved locally, and constitute a personal "map" of key terrain in cyberspace. Organize your hard drive and save the good stuff. Use your electronic mail program, such as PINE, to maintain electronic files with copies of messages from key contacts sorted by topic or area of expertise.

4012. The World Wide Web

The World Wide Web is a true multi-media environment which moves well beyond Gopher's linking of documents and sites, to allow true "hypertext" and "hyper-linking" of images to sounds, sounds to text, documents to other documents, and sites to other sites.

Readers can jump from the middle of a document to some supporting or related document, navigating the Web just like they might move through a library, pulling a reference volume off the shelf upon encountering an unfamiliar term. The Mosaic browser made the Web extremely easy to use, and the work that went into Mosaic was used to create the Netscape browser, which led to the creation of a billion dollar company.

The biggest problem with the Web today is that because it is multi-media, it is a band-width hog, and the demand for access is overwhelming most service providers. There will probably be a slow-down in the Internet in 1996, because a new performance plateau is achieved by the industry.

Users of the Web environment also require a special kind of Internet access, called SLIP, rather than the normal electronic mail and gopher text capability.

Appendix E-1 contains details instructions on how to explore the Web, and how to use different tools.

Here are four examples of useful Web sites. The first is a site dedicated to providing information about different countries; the second focuses on open sources and methods, and includes a full year of its newsletter; the third is a current news service focused strictly on the intelligence profession; and the last is the main access point to all federal government databases and bulletin boards that are accessible to the public.

<www.embassy.org>
<www.oss.net/oss>
<www.awpi.com:80/IntelWeb/>
<www.fedworld.gov>

4013. Where the Web Has Been, and Where It's Headed

The Web relies on Hypertext Markup Language (HTML), which in turn is an open and evolving document creation standard that will permit new applications to work on any standard document.

While running a Web site is technically demanding, many companies are now providing Web space (called a Home Page) for users, just like management companies buy and rent space in commercial buildings. Individuals have the option of hiring a "virtual" server" and obtaining their own domain name, such as "ANALYST.COM".

Security is an issue. Many Web servers do support secure connections, so a user can be sure that the information passing between his or her browser and the server is confidential important when passing credit card information, or other sensitive personal information. Password access can be complicated, so today most home pages and web servers are "wide open".

The next step will be for widely accepted commercial transaction standards to emerge; when this happens we're likely to see it happen quickly, just as point of sale (POS) devices (e.g., credit card swipe readers) have appeared at most retail stores. Digital cash, called by some "cyber-cash", is likely to be commonly available by 1997.

Popular Web sites attract thousands of users per day, and many include advertising graphics on their sites, being paid by the number of "hits" or "page views" they guarantee advertisers. Several companies provide auditing services to verify how much visibility sites provide advertisers.

The Web is likely to make virtual consulting by individual a real possibility, and permit many experts to establish part-time or full-time "cottage industries" selling their expertise to people all over the world in return for digital cash. This is like to cause a number of governments great concern, and may lead to a "virtual taxation" regime--the latter, will however, be very difficult to impose in a world where many encryption alternatives are available.

The professional analyst should think of the Web as a virtual collection environment, where Web sites can be established, and good content provided, as a means of drawing out expertise and collecting both fact and opinion about the topic in question.

4014. Finding Information on the Web

Like the earlier favorite Gopher, searching for things has led to the creation of special search sites. Some sites are important clearinghouses for links to other sites
Several very powerful full-text search sites have been established.

Four examples, each fully described in Appendix E-1, are listed here.

Yahoo:	<http://www.yahoo.com>
Alta Vista:	<http://altavista.digital.com>
InfoSeek:	<http://www.infoseek.com>
Open Text:	<http://www.opentext.com>

Analysts must naturally be concerned that any search they make might reveal a classified interest, but in reality, most analyst is responding to current events and the analyst can find security in obscurity. Everyone else is searching the same sites at the same time. As long as the analyst is searching and not posting, a very reasonable degree of discretion can be assumed.

The appendices corresponding to this chapter are your best guide to finding information on the Web, and contain a great deal of information which could not possibly be communicated in this short one-hour course.

Explore the Net, and keep a log-book. The Web discovery tools also provide "bookmark" features which allow you to keep a list of especially valuable sites to which you can return regularly.

4015. "Intranetting"

Many companies are concerned about security and create their own internal networks, hiding behind firewalls, which are ostensibly "total" breaks between the internal system and the external Internet.

Intranetting is an important consideration to note, because while such information won't be accessible to the public at large, sources and contacts met through the Internet may themselves have access. An analyst can thus obtain access in only two ways: by being an authorized internal user of the system in question, or by going through a personal intermediary, an authorized liaison, who can conduct internal searches and then transfer to the analyst the resulting data.

Examples of two intelligence community "intranets" are INTELINK and OSIS.

INTELINK is a classified Internet; that is, the Intelligence Community has built a secure copy of the Internet for sharing information, with the ease and efficiency enabled by use of World Wide Web servers and browsers, but in a classified setting. In this case, the "firewall" is an air gap, with no direct connections to the global unsecure parent.

OSIS, standing for "Open Source Information System", is a "virtual private network", where several intelligence agencies use the Internet itself for sharing unclassified information more easily, but software, in the form of firewalls and filters, keeps this traffic apart from the rest of the Internet.

Some of the best information available is hidden from the Internet in private intranet environments. This includes both university and corporate data. Analysts need to identify centers of excellence and then explore how they might obtain authorized access to the available data even if it is not directly accessible through the Internet.

The whole area of "intranetting" demonstrates the critical importance of personal networks--the analyst that identifies and cultivates a network of experts will find that the personal contacts can identify and gain access to data regardless of whether it would have been identified through an Internet search--and the Internet will often be the vehicle used for communicating with those experts, and receiving file transfers from them.

4016. Practical Example #1: Indications and Warning

In each of these four cases, information was quickly shared over the Internet, though in several of the cases the information was also traveling through more traditional means.

Researchers at a Swedish university have published a two-volume set of excerpts from network traffic around the Tiananmen Square incidents, including notes calling for protests at Chinese diplomatic facilities in the West, and information passed out of China via fax and phone (and carried by hand) and resent through E-mail. An analyst following Chinese newsgroups is very likely to have been alerted to these events prior to official reports from the U.S. Embassy or other collection capabilities.

Similarly, details of the situation in Moscow during the coup attempt against Gorbachev and Yeltsin were broadcast over the Internet (Yeltsin used a fax to get his statements to the Western press, however, and Gorbachev taped a statement about his detention using his VCR).

The Intel Pentium problem demonstrated the Internet's power as a consumer awareness channel: the bug that Intel considered minor (it only affected the work of serious mathematical processors) was blown up into a major public relations issue. It did however have significant financial ramifications for Intel stock. Similarly, other corporate or technical news can be studied for tip-offs.

Mathematicians have been using the Internet for the past several years to coordinate attacks on complex factoring and other problems, and their achievements have been widely announced via the Internet as solutions are found. On the other hand (and reminding us of the need for caution) the bogus "cold fusion" research was also spread via the Internet, attracting far more attention than it merited.

4017. Practical Example #2: Cultural Context

The Internet is a rich resource of information on distant countries and cultures. Because it's an open channel for information from virtually anyone with access to E-mail, it can become choked with both information and disinformation, but it's hard not to be able to find something on virtually any topic.

At the very end of your first hand-out you will find some extracted lists of messages and files pertaining to Kuwait, Bosnia, and the United Nations.

In combination, newsgroups, listservs, and web sites provide a rich background about current events and historical context. These passive sources of information--passive in the sense that you can "lurk", also permit analysts to rapidly identify articulate individuals to whom "off-line" questions can be posed, saving the analyst significant research time by providing a local perspective and a sense of a situation that would otherwise require hours of reading and might never result in the kind of insight that can be obtained from someone who is heavily involved in the issues under consideration.

4018. Practical Example #3: Basic Research

While the Internet covers a broad spectrum of exotic information, it's also a good repository for basic information.

Some of the first information resources were library card catalogs (catalog databases were simply connected up to allow searching via the Internet); any other product that could be placed on a disk or CD-ROM might also be placed on a Web host.

Appendix E-2 lists a wide variety of sites especially pertinent to intelligence analysts. Appendix E-3 focuses on popular web sites covering computer resources, news. government, and reference. Examples from both lists are shown here.

MILNET: Open Source Military Information Database
Military Intelligence: 20th Special Forces Group
CIA Country Reports
Department of State Country Reports
CNN Interactive
Reuters NewsMedia
Library of Congress
Britannica Online

4019. Practical Example #4: Science and Technology Collection

Virtually every area of interest can be found through the web and listservs. Every analyst with an S&T aspect to their work should consider searching for selected sites and also subscribing to selected listservs in their areas of interest.

Appendix E-2 lists a number of sites associated with weapons transfers and information warfare, some shown here.

High Energy Weapons Archive
Germ Warfare
Code Names and Numbers for Weapons
IW Database
Defense Information Systems Agency--Information Security
Computer Security Institute

Appendix E-3 lists a starting point for scientific and technical information, elements of which are shown here.

Biographical Information
Directory of Scientific Institutions
Electronic Journals

4020. Practical Example #5: Spotting and Assessment

The Internet is both open and public, and capable of allowing private communication. As users interact on mailing lists, newsgroups and conferences, they are seen (or read) by others. Estimates are that roughly 90% of the members of most conferences or newsgroups are "lurkers," that is, only read, and never contribute materials of their own. But a visible poster may attract private E-mail, volunteering information that the sender would like known, but wouldn't be comfortable posting directly.

You can often bait the hook, by offering (sincerely) to exchange information that you are authorized to share without violating copyrights. Sometimes your personal impressions as a professional analyst, and copies of articles that you have published in the unclassified literature, are enough to attract your counter-parts into dialogue.

Occasionally you may find yourself dealing with an electronic walk-in, someone who is volunteering information which appears credible and which may also be subjecting the individual in question to some risk if discovered. Such cases should be brought to the immediate attention of HUMINT and counterintelligence through established channels, not to give them up, but to ensure that the analyst has a full range of HUMINT and CI assistance in developing the source or--in some cases--turning over the source to a clandestine case officer.

Analysts who find names and backgrounds of interest always have the option of requesting security traces through channels. Working with HUMINT professionals can be a rewarding way of furthering any analyst's understanding of the network of human experts available to support the all-source project. Analysts can help the HUMINT discipline by identifying high-value targets for clandestine recruitment, and as the same time receive HUMINT assistance and cooperation in developing approved overt human sources, for whom funds can be budgeted.

4021. Second Caution: Mischief in Cyberspace

Because of the "faceless" nature of the Internet, it's possible to make mischief, from harassment to propaganda on a grand scale. "Astroturf" and "whisper campaigns" are where a few individuals (or even a single individual) can create numerous postings, attributed to a great many more people, in an effort to create a seeming consensus toward an issue or candidate.

"Spamming" occurs when an individual sends numerous and inappropriate postings to large audiences, through numerous mailing lists or newsgroups. This is at best annoying, and can, at worst, severely disrupt recipients' systems, choking their Internet connections or incurring significant costs if they have to pay by the volume of information received.

Because there are few if any restrictions on the collection of information from Internet search tools, and one should presume that, unless encryption is used, communications over the Internet can be at least noted, if not intercepted, one should be concerned about traffic analysis (on the other hand, if one owns a search tool site, one can readily gauge what issues Internet users find interesting!).

Trojan horses and viruses are malicious code that could be placed in resources made available on the Internet; while troublesome, they can be easily avoided by scanning any downloaded software, or limiting collection to text only. Analysts need to be aware that

icons are now also known to be active, and executable code can in fact be imported when importing "non-executable" data and graphics.

4022. Pulling It All Together

This one-hour introduction to the Internet as a tool for all-source analysis has provided you with an overview of various tools and sources you can find on the Internet.

Here we show a sequence of steps which an analyst can pursue to exploit the Internet in support of a specific project.

Step 1.	Search for Background
Step 2.	Identify Experts
Step 3.	Identify Lists and Newsgroups
Step 4.	Send Some Electronic Mail
Step 5.	Post Some Queries on Conferences
Step 6.	Establish a List or Web Site
Step 7.	Host a "Face to Face" Working Lunch
Step 8.	Contribute Unclassified Information
Step 9.	Develop Collaborative Relationships

An initial Web search can readily identify background documents. Together with a search of newsgroups and listservs, a number of experts commentators can be identified through their public postings.

Depending on the sensitivity of the query, the analyst can then take an active role by sending selected electronic mail or posting some general queries. Analysts should be mindful of Net protocols and the general expectation of the barter environment which characterizes the Internet--a sense of professional sharing and the expectation of exchanged favors.

At a more sophisticated level, analysts can work with appropriate infrastructure personnel to create a list or web site focused on their specific interests. This can serve as a magnet for individuals world-wide. In the early stages of the list or web site, it is useful to "salt" it with an introductory document that is deliberately loaded with "hot" words or keywords. Also, it is important to note that direct contact with the more popular clearinghouses can ensure that the site is properly listed and described.

Finally, the analyst can use the Internet to keep in touch with specific individuals, to coordinate face to face meetings, and generally to develop collaborative relationships with private sector peers eager to share unclassified information.

4023. Anticipating Coming Changes

Electronic commerce, as it arrives, will limit some formerly open resources (as people begin to charge what they'd had to previously give out for free) but will also help to fund efforts (such as cataloging) that are sorely needed, and will let others feel comfortable putting new resources online. As the volume of materials become such that most information needs can be met via the Internet (one-stop shopping) such catalogs and directories will become critical.

Since human searching is a chokepoint (there's only so much one person can scan through), we'll see tools for automating searches, or even turning them over to software "agents" to do the heavy lifting of browsing through hundreds or thousands of sites in search of relevant materials.

We've already seen some restrictions on Internet content, such as bans on "indecent" content. Some countries have much stricter restrictions on speech than the US, but the Internet, as a global system, will challenge attempts at censure. Access will continue to expand, especially to let travelers more easily access the Internet when away from home or office.

Some things, however, will NOT change. Analysts will continue to encounter a world of knowledge in which most of the information they really need is in hard-copy, is in a foreign language, and is somewhere else. In all these cases, it will be people who can help the analyst discover key data, discriminate between good and bad data, and distill masses of data into raw information which can then be considered by the analyst as part of the all-source intelligence process.

4024. Conclusion: A Work in Progress

Not only has the Internet changed dramatically over the last several years, the rate of change appears to be increasing. Commercialization is likely to cause further bends in the curve, as it will suddenly become possible for easy electronic sales of information, creating incentives both for companies to put resources online, and for others to create indexes and catalogs to those resources. Low cost global access and virtual conferencing are a rapidly approaching reality.

The Internet isn't the sum of all the world's information, but it is a good jumping off point, and grants easy access to potential sources and experts worldwide. It can also provide new avenues of access to traditional intelligence sources, e.g., as a spotting and assessment tool. It certainly allows activities that would have been impossible previously because of time and distance (such as convening a panel of experts on a fast-breaking topic), and will only improve in that regard as most potential participants in such activities get online themselves.

The analyst's access to both raw data and alternative perspectives is growing quickly because of the Internet; analysis will never be the same. However, the process of analysis has not changed--in evaluating the potential contributions of the Internet to the all-source analysis process, the analyst must remember security, remember source authentication, and remember completeness.

Chapter 5

OPEN SOURCES AND MILITARY CAPABILITIES

5001. Purpose of the Chapter

This chapter focuses on the practical application of open sources to military intelligence analysis requirements.

We will begin by introducing a model for integrated all-source analysis which illustrates the critical importance of geographic and civil factors in evaluating the threat at each of the levels of analysis. While open sources are useful in conducting research and developing intelligence estimates about military capabilities in isolation, open sources are most useful to the military intelligence analyst when used to develop a broader analytical model.

The general utility of open sources for military intelligence analysis, and the specific utility of open sources at the strategic, operational, tactical, and technical levels of analysis will be discussed.

Next we will look at specific private sector capabilities for collecting and processing open source information. Commercial imagery, private sector order of battle information, and networks of experts available for consultation will be reviewed in general terms.

Finally this chapter introduces the student to the Expeditionary Factors study developed by the Marine Corps Intelligence Activity, and used for this class because it is the only current and authoritative intelligence analysis product which relies exclusively on open sources, is unclassified in its final form, and covers a broad range of mission area factors for eighty countries specifically chosen because of the likelihood that a Marine Air Ground Task Force will be engaged in non-combatant or combatant missions in the countries

There are three Appendices associated with this chapter--Appendix A, which was introduced in Chapter 1, and Appendices F-1 and F-2.

5002. Model for Integrated All-Source Analysis

The four levels of analysis first popularized and thoroughly explained by Edward N. Luttwak in his book, *STRATEGY: The Logic of War and Peace* (Belknap, 1987), are most easily understood with an illustration. The Marine Corps Intelligence Center expanded this model by distinguishing between military, geographic, and civil factors. The third hand-out is a complete description of the model, including a summary illustration on page v.

When the model was first developed, a specific Middle Eastern country was used by the Marine Corps, in consultation with DIA, CIA, and NSA analysts responsible for that

country. to test assumptions. Their tank warfare capability. traditionally assessed as a high threat. proved on examination through the four levels of analysis, to be a high threat only at the technical level, because the country had an inventory of T-72 tanks, the best tanks that money could buy at the time. At the tactical level of analysis, the threat dropped to low because the tanks were not being maintained, in fact were being cannibalized for parts, and the troops were not trained. At the operational level, the tank threat increased to medium because there were a significant number of tanks available around the country. Finally, at the strategic level of analysis,the tank threat again dropped to low because it was not possible for the country to sustain tank operations for very long.

This analytical model becomes even more useful when we introduce the three analysis domains--military, geographic, and civil--and consider how the three domains interact at each level of analysis. At the strategic level, military sustainability, geographic location, and civil allies are the essential elements of employable power. At the operational level, military availability. geographic resources, and civil instability bear on the regional influence of the target country. At the tactical level, military reliability, geographic terrain, and civil psychology come together to determine battlefield dynamics. Finally, at the technical level, military lethality (and accuracy), geographic atmosphere--specifically temperature--and civil infrastructure including communications and computing systems, help determine the balance of power.

In short, the threat varies depending on the level of analysis. Open sources provide both raw information, and a general context, for this more complex form of analysis.

5003. General Utility of OSINT

There are three major ways in which open sources are very useful to the defense intelligence analyst:

First, open sources are very quickly and cheaply available, and even when the full weight of the traditional classified capabilities are being brought to bear, will offer the analyst--and the supported policy maker or commander--a rapid orientation useful for planning purposes.

For example, in one case where U.S. forces were being directed to deploy quickly to a remote area of Turkey, it was an open source reference which quickly identified the nearest airfields and their runway, navigation, and bunkerage capabilities.

In many cases, open sources may be the only available source for a significant period of time. As military operations other than war, and unanticipated contingencies, tend to occur in Third World countries that are Tier 3 or Tier 4 in terms of standing intelligence priorities, it will often be the case that the military intelligence analyst and the operating forces will be forced to rely exclusively on commercial imagery, private sector news broadcasts, and direct contact with overt human experts, in order to produce intelligence.

The second area where open sources have a significant value is with respect to collection management. By providing a rapid and inexpensive orientation, a "first cut" on what is known and what is not known, open sources has enable the analyst to develop a collection management strategy which avoids wasting precious classified resources of essential elements of information which can be handled by open sources, and which focuses the clandestine and technical capabilities on "the hard stuff".

Finally, open sources are very helpful when conducting joint or coalition operations, including support to law enforcement, where there are constraints on the sharing of classified intelligence, and it is considered prudent to avoid sharing sensitive intelligence and the means by which the intelligence was obtained.

5004. Strategic Intelligence

At the strategic level, military sustainability, geographic location, and civil allies are critical elements of national power. Much of the information needed at this level is in fact available through open sources.

In the indications & warning arena, open sources can--through the technique of content analysis and comparisons of content over time--provide very reliable gauges of national intent. In fact, the Office of Strategic Services and its original Research & Analysis Branch made the analysis of open sources an art form--by studying what the German leaders were telling their own people through the public media, the OSS was able to develop estimative intelligence.

Open sources are also critical in two areas traditionally not within the normal scope of classified systems--demographic intelligence and cultural intelligence. Today, as organizations such as the U.S. Information Agency begin to apply intelligence methods to open sources, and adopt a collection and reporting role in these areas (as was recently recommended to their oversight body, the U.S. Commission on Public Diplomacy--the analyst may find that one of their most important sources for partially analyzed open source information is the traditional consumer of intelligence.

Strategic generalizations are not yet a well developed aspect of national intelligence support to acquisition, but as the concluding chapters will demonstrate, a potentially important means of money and improving system performance. To take just one example: if aircraft are built to a standard "warm" day, and the "real world" of contingencies is in fact a "hot" world, then by definition our forces will be using aviation resources which can fly half as far and carry half as much as advertised when operating at the "optimal" temperature. When European truck manufacturers adopt a strict policy of never selling a vehicle weighing over thirty tons to a Third World county, the viability of some of our heavier ground combat vehicles must be called into question.

At the strategic level open sources are helpful in understanding the context for security assistance programs, and in developing support for specific programs from the public, the press, and the policy community.

5005. Operational Intelligence

At the operational level, military availability, geographic resources, and civil instability influence the regional effectiveness of individual countries.

It is very helpful for an analyst to develop regional generalizations, to establish an understanding of order of battle averages, and of geographic and civil constraints characteristic of the region. Third World operations are inherently different from the European theater operations against a Soviet threat for which most U.S. mobility and weapons systems were designed--the analyst that understand both the limitations of our own systems in the Third World, and the possible advantages which accrue to those fighting on their home ground with equipment designed for their home ground, will probably produce more useful intelligence products.

Open sources are especially valuable to the theater commander and those supporting the theater and its Joint Intelligence Center because most contingencies will not warrant major collection campaigns from classified sources. This is true both in the planning phrase, and in the execution phase when it is necessary to coordinate logistics and other matters with joint and coalition partners. At the operational level, where the greatest mixture of allied and U.S. services is to be found, and there is a greater involvement of civilian agencies from both the U.S. and other countries, secrecy can be an impediment to understanding and consensus, and open sources can have a corresponding simplicity which increases cooperation and improves coordination.

As the theater staff plans the allocation of resources, a sound understanding of the region and the capabilities of all parties to the operation, largely gathered through open sources, can help determine what should be left on the pier, what additional capabilities are needed from the national level, and what to expect or request for allies.

5006. Tactical Intelligence

At the tactical level, military reliability, geographic terrain, and civil psychology are essential determinants of battlefield success.

At this level, where combined arms coordination at the 1:50,000 scale is essential to the art of maneuver and the control of precision munitions, commercial imagery is often the only available source which can be brought to bear. National collection capabilities are not well-suited for wide area surveillance, they were designed for point targets, and will naturally be much in demand for the development of target intelligence.

Commercial imagery, notably SPOT imagery at the 10 meter level of resolution (meaning you can see an object ten meters wide on the ground), is not only fully suitable for the creation of 1:50,000 combat charts with contour lines, but has also proven to be more than acceptable to the U.S. Air Force as the foundation for targeting precision munitions, and as the source for digital elevation data used to create sophisticated simulations for mission rehearsals and other needs.

It is important to note that commercial imagery requires the addition of "ground truth" points to orient the image and establish precise geo-spacial accuracy. Such precision is obtainable in two ways: through the integration of precision points (e.g. key intersections) obtained from the National Reconnaissance Office through the Defense Mapping Agency, or through Global Positioning Satellite (GPS) recordings taken by human assets actually on the ground.

Open sources are very useful in emerging target areas which have not been heavily covered by classified capabilities. The Director of the Non-Proliferation Center, for instance, has stated publicly as much as 80% of his final intelligence products are based on open sources; in counter-narcotics operations, open sources--including investigative journalism in Latin American newspapers--has proven to be accurate and comprehensive....so much so that the U.S. Southern Command enlisted the Department of Energy laboratories (Los Alamos and Sandia) to collect and process open source information from Latin America, with the result that tactical interdiction operations were mounted. This story is told in *SHARING THE SECRETS: Open Source Intelligence and the War on Drugs.*

5007. Technical Intelligence

At the technical level, military lethality (including accuracy), geographic atmosphere, and civil infrastructure are important determinants of battlefield success.

As was discovered during the Gulf War, open sources are the best and often the only source of information needed to "map" the target area's C4I infrastructure, and develop information warfare operations.

Open sources are also the backbone for planning logistics operations and mobility systems, since information about airheads, ports, rail and road networks, and related support systems are all a matter of public record. There is however, an aspect of the open source world that is not obvious at first: much of what is counted as "open" source is in fact grey literature, limited edition literature in a foreign language. Collecting and processing open source information is not necessarily easy!

Finally, open sources are the foundation for long-term intelligence efforts against scientific and weapons research. Unclassified civilian research, and publications by civilians employed in defense-related industries, have long been a critical foundation for intelligence in support of major acquisition programs. In fact, one tip-off for intelligence analysts is the

disappearance from a literature of a particular expert, or a particular line of inquiry.

5008. Commercial Imagery for 1:50,000 Maps

A ten meter image from SPOT Image Corporation can be processed to integrate both the standard military grid lines, and the contour lines that most people do not realize is achievable from SPOT panchromatic coverage.

It is especially important for analysts to understand that this commercial system has been in operation for over a decade, and that virtually the entire world has been imaged, with most images being less than five years old and in ground station archives--this imagery is available within 24 hours.

Source imagery is not enough by itself, as was mentioned earlier. Additional processing is required to establish elevation points and precision points, and additional time is needed to produce the 1:50,000 combat charts necessary for combined arms operations and especially infantry patrolling....but the source imagery, traditionally the stumbling block when attempting to use national systems to obtain wide area coverage in a crisis, is no longer the obstacle to producing maps.

By combining SPOT wide area coverage with NRO precision points, under the management of the Defense Mapping Agency, we can have 1:50,000 maps right now.

5009. Commercial Imagery for Mission Rehearsal

The same commercial imagery that is used to produce 1:50,000 combat charts can also produce superb three-dimensional simulations and perspectives that can be used to study beach approaches, potential landing zones, and nape of the earth flight corridors.

5010. Order of Battle Information

The former Soviet Union and the People's Republic of China are probably the only two countries where the U.S. intelligence community could state with certainty that it possessed more accurate information about the order of battle than was available from open sources. Perhaps this is even true of other denied areas such as North Korea and Cuba.

Yet when it comes to virtually any other country, the information collected and processed by Jane's Information Group, publisher of the Jane's series of books and CD-ROMS which cover all types of mobility and weapons systems, is the world standard. In fact, in a graduate thesis by (then) Major Robert M. Simmons, titled "Open Source Intelligence: An Examination of Its Exploitation in the Defense Intelligence Community", our own military intelligence analysts are quoted as saying "reference publications such as Jane's often provide first indications of weapons modifications and sales" (page 112).

The Jane's series of references books and CD-ROMS is now also available online by special subscription, and the material is kept current by a global network of overt human assets as well as extraordinarily good relations between Jane's and most Ministries of Defense. Analysts need to know that as good as the Jane's publications are, only 20% of the information known to Jane's is actually made public. "Confidential" reports on training, morale, and other issues can be obtained by special arrangement.

Jane's is also helpful in understanding the order of battle for non-traditional information. Jane's has provided orders of battle for the warring clans in Somalia, and is considering providing a similar service with respect to transnational criminal organizations.

Another private sector service that can be helpful to analysts attempting to understand Third World or non-traditional orders of battle (e.g. of revolutionary groups) is offered by Rapport Research & Analysis, representative of a small number of elite organizations, most with Special Air Service or similar backgrounds, who specialize in making available highly trained interrogator-translators who are able to canvass refugee and exile communities to identify sources and then systematically develop the needed information as well as leads to in-country sources of potential value.

5011. Historical and Estimative Analysis

In the age of distributed information, the concept of "central intelligence" is difficult to implement, and even unnecessary. While a central coordinating authority, and bodies of trained analysts with clearances, are both needed, there is now a very robust "virtual intelligence community" which can be harnessed to develop significant amounts of historical and estimative analysis based solely on open sources.

Oxford Analytica, a U.S. owned company based in Oxford, England, is the best private intelligence agency in the world, and its excellence is based strictly on analysis. Founded by Mr. David Young, who worked with Dr. Henry Kissinger when the latter was National Security Advisor to the President, Oxford Analytica specializes in producing daily regional reports which concisely address three questions: what's right in the news that needs elaboration? what's wrong in the news that needs correction? and what weak signals are we seeing that merit scrutiny and an estimate?

This organization covers the world. For Somalia, to take one example, over a period of two years they produced over twenty two page reports on UN operations in Somalia, US foreign policy toward Somalia, and US operations in Somalia.

How does this "best in class" organization work? They start by having a fifteen person team, organized by region and function, review all news wires and major periodicals on a day to day basis. They then bring in the Dons of Oxford in small groups rotated regularly, and draw on the expertise resident at Oxford University—in effect they have harnessed the centuries of accumulated experience, and integrated that experience into their

daily operations. Then, when special reports are desired, they have a global network of 1,000 experts, culled down from 2,500, to whom they can turn at any time with a request for a two-page report which integrates personal calls to key decision-makers, and is drafted at a level suitable for a President, Prime Minister....or you, the analyst preparing intelligence products for policy-makers and commanders.

5012. Networks of Experts

The most significant difference between elementary and advanced analysis is that the first draws primarily on published information, and the second draws primarily on direct contact with world class experts.

Most published information is out of date by the time it is published. In addition, the intelligence community, which specializes in secrets, is not trained, equipped, and organized to collect open source materials. The result, well documented in the thesis by Major Simmons cited earlier, is that analysts have very limited access to the broad capabilities in the private sector. Advanced analysis requires recourse to a network of expert colleagues in the private sector who can serve as a collection filter, and quickly identify key documents, comment authoritatively on emerging trends, and generally help the advanced analyst to fully exploit open sources, while also adding the unique value that is inherent in all-source analysis.

LEXIS-NEXIS and DIALOG, the two major online news services, are recommended to analysts not for the massive volume of printed information they can provide, but for something far more subtle: the identification of journalists and sources who--through their by-lines or their being cited, might aid the analyst in leap-frogging over old published information and into the future.

Complementing the online services is the Institute of Scientific Information, and its two major publications, the *Social Science Citation Index* and the *Science Citation Index*. These are unique databases, available both in hardcopy and online, because they allow the analyst to take an older work known to be relevant, and to quickly identify, right up to the current week, who has cited the older work. In essence, the analyst can quickly reach the most current and authoritative experts on any topic through this capability, with the added advantage that frequency of citation conveys a sense of peer evaluation.

Professional associations and associations of retired military personnel are mentioned simply to highlight the fact that the entire world is full of knowledgeable people, most of whom would be happy to respond to questions. Finding the right person and asking the right question is becoming more important than "keeping up with traffic".

5013. Expeditionary Factors Study

The *Expeditionary Factors* study sponsored by the Marine Corps Intelligence Activity and carried out by PRC under contract, is a second generation effort, and current as of 1994. It is a showcase for OSINT, as it is the only high-level intelligence community product that relies exclusively on open sources, and is published in an unclassified form (For Official Use Only).

The first generation study was completed in 1990, and was called *Overview of Planning and Programming Factors for Expeditionary Operations in the Third World*. Copies of the original analysis model, and of the strategic generalizations chapter from the original study (this chapter was inadvertently overlooked in the follow-on study and thus was not updated), are included as hand-outs.

The other unique aspect of the Marine Corps study was its focus on countries which the Marine Corps felt has the "highest probability" of requiring entry by U.S. forces, rather than on the traditional "worst case" priorities focus. The original list of countries, approved by the Marine Corps flag officer community, was comprised of 69 countries. The current list includes 80 countries, almost all of them in the Third World.

The Marine Corps approach, besides focusing on open sources and an unclassified product, was also unique in that warfighters--operators--were asked to define low, medium, and high degrees of difficulty for each mission area, and this was then converted into a five point scale that can be graphically depicted.

This three-volume hard-copy set, also available on CD-ROM, is an excellent ready reference for planning, and is available. To obtain ordering information, call or fax the numbers shown here.

5014. Strategic Generalizations

Having introduced the *Expeditionary Factors* study, we now turn to some of the strategic generalizations which emerged from its predecessor and remain constant today.

The expeditionary environment is complex and lethal. Experienced infantry, modern armor, sophisticated artillery, night/all weather aviation, and integrated air defense systems are all too often characteristic of the "Third World".

The "cultural terrain" is steep, with 40 of the original 69 countries speaking Arabic or a primary language other than English, French, or Spanish, and most practicing Islam or an eastern or trivial religion.

The aviation temperature is uniformly hot, with a sustained heat index of over 80 degrees, which automatically reduces both lift and range of aviation platforms significantly.

There is an equal mix of mountains, deserts, jungle, and urban terrain. We must be ready for all four. Cross-country mobility was non-existent in 60% of the countries and severely constrained in another 20%. When combined with an average bridge loading capability of no more than 30 tons (not in the study but well-known as the civilian limit for truck weight), this suggests real difficulty for existing concepts of ground maneuver.

Average line of sight distance was under 1,000 meters, with only eight of the 69 countries offering stand-off engagement ranges of over 2,000 meters. In the absence of carrier aviation, the Navy's standard guns are no match for the coastal artillery and missiles of many of these countries.

There were no 1:50,000 maps for 22 of the countries, and old maps for ports and capital cities only of another 37 of the countries.

Finally, between half the countries having no usable ports, and most capital cities with their Embassies being beyond the round-trip range of a CH-46 flying from the five fathom line, Non-Combatant Evacuation Operations presented real challenges.

5015. Commission on Intelligence

Open sources are gradually being accepted as an important part of the all-source production process, but there are still many obstacles to its full integration into national and defense intelligence.

The Commission on Intelligence, popularly known as the Aspin or Brown Commission, was created by Congress to thoroughly evaluate the U.S. intelligence community. One of the closed hearings held by the Commission, on 3 August 1996, addressed open sources. Among the four individuals testifying were the National Security Advisor to the President, Dr. Anthony Lake and the founder of OPEN SOURCE SOLUTIONS, Inc., Mr. Robert Steele.

At the end of the session, a Thursday afternoon, General Lew Allen, USAF (Ret), challenged Mr. Steele to join in a benchmark exercise testing private sector capabilities against those of the entire Intelligence Community. Burundi was chosen as the target, and a deadline was set for 1000 the following Monday.

The Commission was surprised by the results. In short order, they received order of battle information on tribes from Jane's Information Group; strategic commentary from Oxford Analytica; a list of available Russian maps down to the 1:250,000 level from Eastview Publications; a list of authoritative journalists from LEXIS-NEXIS; and a list of expert academics and others from the Institute of Scientific Information. Later, not part of the initial response, it was determined that SPOT imagery was available for all of Burundi and could be used to produce 1:50,000 combat charts and mission simulation programs.

As a direct result of this benchmark exercise, the Commission included in its final report an extraordinarily detailed and strong statement on the importance of open sources. The Commission noted that OSINT has limitations, but went on to state that the Intelligence Community has been "inexplicably slow" to provide analysts with access to open sources; that the Commission views such access as "critical" to the all-source analysis process; and that the Commission believes that open source access should be a top priority for the Director of Central Intelligence and a top priority for funding.

5016. Conclusion

Commercial imagery is a useful example of how open sources can support and enhance national intelligence capabilities:

-- 10 meter commercial imagery provides cheap and fast wide-area coverage, and has the added advantage that most of the world has already been overflown and generally cloud-free imagery are already stored in the ground stations;

-- 1 meter commercial imagery--if U.S. policy and a lack of funding does not derail private sector efforts to create this new capability--can provide urban detail and a closer focus on key targets while avoiding an order of magnitude increase in the cost of maps which would accompany any attempt to use 1 meter for the whole world (not to mention the delay in collection); and finally

-- Classified imagery from the National Reconnaissance Office can provide the eight precision points per wide-area image that are necessary to create a 1:50,000 map to our standards of accuracy for combined arms operation.

The Defense Mapping Agency, or the new National Imagery and Mapping Agency, are ideally placed to manage a truly national program in which private sector open sources and classified Intelligence Community capabilities are fully integrated. This is the ultimate value of open source intelligence--as an integral part of the all-source solution.

What should we conclude from all this? First, it is clear that experts and data reside in the private sector, outside the intelligence community, which are vital to understanding and which should be harnessed in support of the all-source intelligence process. Second, these resources represent a potential source of savings to the U.S. taxpayer, since they are maintained at no cost to the taxpayer, are constantly validated by their survival in the marketplace, and--if properly exploited--permit the expensive classified capabilities to be applies more effectively to "the hard stuff". Open sources provide orientation and context. They do not provide the complete answer in most cases, but rather make the other intelligence disciplines more effective.

Chapter 6

OPEN SOURCES AND OPERATIONAL SECURITY--THE DARK SIDE

6001. Purpose of the Chapter

This chapter was developed by Mr. Richard Horowitz, a licensed private investigator and security consultant based in New York. Mr. Horowitz has served in the Israel Defense Forces, attaining the rank of Captain, and is now studying law in New York City.

This chapter is grounded on the premise that everything needed for the planning and execution of criminal or terrorist activity can be found in open sources. Indeed, an entire industry exists which is devoted to the publication of such material. In addition, equipment designed for one purpose and legally available can be used in terrorist or criminal activity.

The total cost of the publications and equipment presented in this "dark side" chapter is available for approximately $1,800. The chapter is based on the "seeing is believing" principle. Each of the items discussed in this chapter can be ordered by using the complete ordering information containing in Appendix G.

From both a military and a law enforcement point of view, it is critical to understand that even our most poorly-funded and least organized opponents can gain access to relatively sophisticated intelligence collection tools as well as tools of destruction.

This chapter--like all other chapters in this handbook--is unclassified. The key point to emphasize is that everything presented is publicly and legally available. Books on intelligence collection, killing methods, offshore money laundering, and any other aspect of criminal operations can be purchased by calling an (800) number and using a credit card. We must all be aware of how such information might be exploited when acquired by persons seeking to harm or take advantage of others, and specifically, to harm members of the MAGTF in garrison or ashore.

6002. General Considerations

It is a fact of life that society contains those who are morally deviant, socially misguided, or worse. It is of similar importance that our society is based on certain freedoms which cannot be taken away. The combination of the two can results in terrorism and crime as we know it today. Underlying the activities of these individuals and groups is a culture which includes recruitment, indoctrination, education, training, planning, preparation, and execution.

This chapter is not a training manual, though many techniques and methods can be recognized from professional government training. The objective is to create an awareness regarding the availability of open sources for terrorist and criminal activity.

Four general considerations are offered as an introduction to this model:

1) The availability of the open sources to criminals and terrorists, and the extent to which such capabilities exist, does not document a threat *per se*. Each individual command and each individual operation must carry out a threat analysis unique to their circumstances.

2) Everything we discuss in this chapter is available to anyhody anywhere. This includes Colombian drug smugglers, Los Angeles gang members, Korean contract employees on a U.S. Army base overseas, and individual "crazies" seeking media attention by causing deaths or damage aboard U.S. military installations.

3) Information that has been available for years in published form is now available through the Internet. Bomb designs are popular in cyberspace. Periodic press reports tell of teenagers injuring themselves trying to construct a bomb they have read about on the Internet. While this problem will arguably increase, it should not obfuscate the reality that the industry which produces the material in hard copy has existed for many years.

4) Although "high-tech" threats attract more media attention, the reality is that low-tech capabilities are often just as effective, cheaper, and easier to develop. A federal officer can be attacked by a doberman with its vocal cords cut out--a low-tech but very effective means of perimeter security. The bomb used to destroy the Federal Building in Oklahoma City was not a complex construction--it was a simple mix in a large amount.

6003. Open Sources and Radio Interception

Intelligence acquisition, or information gathering, is a crucial first step in planning and executing an operation. The next six slides are devoted to various methods of information gathering: electronic monitoring, operational activity, and computer databases.

This split slide shows frequencies for Air Force One on the left, taken from a book by a California hobbyist which is devoted to monitoring the President. Entitled "Monitoring Air Force One," the volume discusses and lists frequencies of the Mystic Star, Echo/Foxtrot, and FM-FDM-SSB systems, along with identified Secret Service code names.

On the right is the cover of a book published in 1986, entitled *Guide to Embassy and Espionage Communications*, which listed thousands of frequencies transmitted from 55 countries, the International Red Cross, Interpol, and the United Nations.

The extent to which frequencies of federal and state agencies that are intercepted and published presents a security problem is not within the scope of this chapter. The range of equipment and information commercially available indicates a problematic potential or at the very least, can be an incentive for subversive groups to attempt to intercept government transmissions.

Commercially available radio scanners can intercept UHF, VHF, and military bands; some have uninterrupted frequency ranges from 30 MHz to 1.2 GHz and are available in desk top or portable versions. Current law requires manufacturers to block cellular telephone frequencies.

Frequency counters-devices that intercept radio transmissions and display their frequencies on a read-out-are also commercially available.

Monitoring Times runs a column which publishes frequencies used by federal agencies that were intercepted by hobbyists. These agencies include the F.B.I., Secret Service, U.S. Customs, and numerous military agencies. After the World Trade Center bombing, the magazine carried an article listing frequencies used by various Port Authority units, the FAA, and local "press disaster" frequencies. Guides to U.S. and allied official frequencies are readily available worldwide--if a hobbyist can track you, so can a criminal!

6004. Open Sources and Telephone Interception

It is illegal to monitor cellular phone conversations (868-896 MHz). Prior to April 1994 however, radio scanners capable of intercepting these frequencies were legally manufactured and sold. Scanners that blocked cellular frequencies were constructed such that they could be easily modified to intercept cellular transmissions.

Scanners manufactured before April 1994 can still be legally owned or sold. Hence, many scanners capable of intercepting cellular calls are accessible and in use.

Some methods of scanner modification:

-- A Massachusetts company advertises that for $40, they will "unlock" your scanner

-- Journals print schematic diagrams showing how to modify the scanner's circuitry;

-- While the new law prohibits the manufacture of frequency converters- a device that will convert 400 MHz interceptions to 800 Mhz interceptions, many are accessible.

-- For those with technical skills- a cellular phone, which needless to say operates on cellular frequencies, can be modified to intercept other cellular calls.

A book entitled *Tune In On Telephone Calls*, listed in your second hand-out, enumerates frequencies and channels used in various types of telephonic transmissions. Its various chapters cover such operational relevant areas as military aircraft VIP phone calls, satellite phone calls, coastal maritime calls, and cellular calls.

In addition to voice and data interception, there is a commercially available device called a tone decoder which converts the frequencies of a touch-tone dialing system to

numbers and displays them on a read-out, in effect allowing easy identification of those being called by the intercepted telephone, as well as read-out of any other information being transmitted through the touch-tone signals, such as codes and account numbers.

Internationally, for instance from Switzerland, more sophisticated equipment is available, and we should assume that surplus or illicitly obtained military equipment is also available to individuals to whom good intercepts are critically important.

6005. Open Sources and Eavesdropping

Numerous books are in print detailing how to tap a phone or bug a room. Some are quite technical. A manual originally published by the U.S. Department of Justice entitled *Electronic Eavesdropping Techniques and Equipment* has been republished under a different title by a commercial publisher, and is listed in your second hand-out. Please note that "old" techniques can be very effective, especially if there is very little emphasis on operational security against civilian opponents!

In April, 1995, U.S. customs officials raided 40 spy shops in 24 cities that were illegally selling eavesdropping equipment smuggled into the United States from two Japanese companies; 11 people were charged with crimes a result. Termed "electronic surreptitious interception device," among the equipment smuggled into the United States and sold by these shops:

-- telephone transmitters with a range of 400 meters

-- bugging transmitters with a range of 1,000 meters

-- ball-point pen transmitters with a range of 200 meters

-- A/C line transmitters-attached to the line, behind the wall outlet and permanently operates on its current-with a range of 200 meters.

From documents filed in court by the U.S. Government, from October 1993 through February 1995 a total of 161 shipments of 4,367 eavesdropping devices took place. The devises had an estimated retail value of $2,972,517.

Companies also publish electronic plans enabling an individual to assemble his own equipment. These schematic diagrams include automobile tracking transmitters, bugging transmitters, telephone transmitters, a transmitter locator, and audio amplifiers.

Bottom line: assume your are "on the air" unless certain the circumstances are secure!

6006. Open Sources and Undercover Operations

Undercover operations is a term used to describe various types of activities designed so that the fact they are taking place is not recognized, or, if recognized, not for what it really is. The general purpose of undercover operations is generally either to affect a change on a target or to gather information about a target.

Manuals for private investigators, as well as training manuals for law enforcement from various countries have made virtually all aspects of undercover operations a matter of public record. There are manuals on undercover operations in general, on developing clandestine human networks, on surveillance, on lockpicking, and even on elicitation and pretext calls, a very common technique for obtaining information.

Books are in print containing prepared scripts for obtaining personal and financial information from people. One book opens with a chapter entitled "Establishing Rapport and Overcoming Objections." Complete citations are in your second hand-out.

This slide shows two illustrations, one from a manual on surveillance techniques, the other from a manual on lockpicking. Complete citations for both are listed in your second hand-out.

Lockpicking tools are legally sold; prices can start from about $25. The law does not criminalize possession of lockpicking tools unless the person possessing the tools "evinces an intent" to use them for burglary. To quote the New York State law:
"A person is guilty of possession of burglar's tools when he possesses any tool, instrument, or other article adapted, designed or commonly used for committing or facilitating offenses involving forcible entry into premises...under circumstances evincing an intent to use or knowledge that some person intends to use the same in the commission of an offense of such character."

It merits comment that with the limited number of known aerial and maritime surveillance platforms that the U.S. Coast Guard has to patrol the drug routes from Latin America to the United States, it would be an easy matter for drug criminals to establish both passive observation posts near airfields and ports, and also active aerial and maritime surveillance capabilities. In brief then, criminals and terrorists who understand the value of intelligence collection, can easily establish significant capabilities which can frustrate official government programs.

6007. Open Sources and Interrogations

Criminals and terrorists have access to professional training and professional interrogators. Even the most reputable firms, such as E2G and Rapport Research in the United Kingdom, both staffed by highly trained former Special Air Service (SAS)

interrogator-translators, will be happy to offer training and perhaps even surveillance and other services to those who come to them with cash and an appropriate cover story.

In the United States, the "Soldier of Fortune" circuit includes many training and exercise schools where useful knowledge can be learned.

This slide listed selected chapter headings from two books readily available on the open market, one on psychological interrogation techniques, the other on physical interrogation techniques.

As transnational crime becomes a greater threat to national security, and the military become more involved in support to law enforcement operations, it merits comment that operational security and "need to know" are just as important in this environment as in any other.

Indeed, one of the distinguishing aspects of transnational criminal operations are their ruthlessness, and the ease with which they can select and coerce civilians to help them on a one-time basis by threatening to kill their loved ones–how many Pacific Coast fisherman do you suppose would refuse to carry one load of drugs if they were assured that it would only be a one-time risk, and that their loved ones were being held under surveillance and would be killed if the fisherman did not cooperate?

6008. Open Sources and Direct Research

Previous chapters have dealt with the rich range of open sources, and how to develop intelligence from open sources, including international sources and the Internet. The point to emphasize is that terrorists and criminals have access to everything in the open source world described by this handbook.

Major criminal and terrorist organizations are fully cognizant of the utility of open sources, and know how to do their homework. They know the power of computerized search & retrieval, and the value of information in support of their operational objectives.

For the purposes we are discussing, the computerized databases which can be accessed by anyone in the public, including criminals and terrorists, can be divided into the following three broad categories:

– Media: available are not only *The New York Times*, *Washington Post*, and *Wall Street Journal*, but numerous local newspapers such as *The Rocky Mountain News* (Denver, CO), *The Commercial Appeal* (Memphis, TN), and *The Times-Picayune* (New Orleans, LA), and foreign newspapers such as *Le Monde*, *The Irish Times*, and *The Prague Post*. Wire services- UPI, AP, Reuters, and the Xinhua News Agency (China), for example, are also accessible.

-- Business and public records: corporate and bankruptcy filings, SEC filings. property ownership, criminal background checks, driver's licenses. Financial news. Companies combine mailing lists of hundreds of marketing companies, resulting in a database which can identify the address of a person or family, or their neighbors. Reverse phone directory-enter name, retrieve a person's phone number, or enter a phone number and retrieve the name of the person.

-- Specialized trade and industry information: databases exist that specialize in information unique to a particular industry or country, generally in the form of periodic newsletters, and are a valuable source of information. This slide lists some of the sources of possible use to criminals planning electronic thefts or money laundering operations, and terrorists planning specific acts.

A classic example of the basic utility of research: on 3 May 1993 a complete report was carried online about the meeting of the Nuclear Regulatory Commission, entitled: "Commission Hears Options for Dealing with Vehicle Bomb Threats". Discussed in detail online: the four options regarding physical barriers surrounding nuclear power plants.

6009. Open Sources and Executions

This slide is a combination of extracts from two books, one on killing and one on creating silencers.

Literature on killings and executions are graphic and the methods described are real. A six volume work entitled "How To Kill" is representative. Volume One begins with "Chapter One: The Target," complete with an anatomy chart highlighting sensitive parts of the body. Subsequent chapters are devoted to various types of killings. Appendices entitled "The Signs of Death," "Your First," and "A List of Poisons" follow the chapters.

A separate body of literature exists on the use of knives. One book has the topical heading of "anatomical considerations" followed by diagrams entitled bleeders, immobilizers, quick kill, showing the respective spots on the body. The book ends with an appendix entitled "Suggestions for Further Study."

Books describing how to construct silencers from household material exist. Attaching a slightly filled plastic soda bottle or a container of three tennis balls to the barrel of a gun are crude methods. More technical methods requiring metals are detailed. In a chapter entitled "Your Last Chance To Be Legal," one book discusses the various federal forms that need be filed in order to request to manufacture a silencer.

Manuals on improvised weapons show how to install a gun or firing mechanism in, for example, an umbrella, belt buckle, flashlight, briefcase, cigarette lighter, or tobacco pipe.

The same publisher selling books on how to kill supplies a book on how to dispose of dead bodies, including a technique on removing a bullet from a body without leaving evidence.

Full citations to all the books cited in this chapter are contained in Appendix G.

6010. Open Sources and Explosives

This slide is also a combination of several diagrams to illustrate the nature of the information that is available in open sources about creating and using explosives.

Improvised explosives, and bomb design, are topics with the most published literature. Numerous books in a "cook book" form describe how to mix readily available chemicals into explosives. Mixing soap flakes with gasoline so as to allow the gasoline to stick to its target instead of dripping off before igniting is discussed in a book and in a video on making explosives.

Separate books exist on how to make C4 and Semtex.

While these books generally have a disclaimer that the information contained therein is for educational purposes only, a book entitled "Professional Standards for Preparing, Handling, and Using Explosives" is available from the publisher.

From a catalogue:

DEATHTRAP! The Video: There is no better way to learn about improvised explosive booby traps used by international terrorists than to watch live, on-camera demonstrations of their construction, deployment and detonation. DEATHTRAP! The Video is a chilling seminar in just that - how terrorists modify innocent everyday items to conceal insidious explosive booby traps designed for maximum shock and lethality. You'll see ingeniously disguised devices made out of books, music cassettes, mugs, portable tape players, foot powder cans, alarm clocks, videocassettes, mousetraps, and more, all triggered by simple electrical, chemical, or mechanical means.

The video costs $29.95 and runs for 35 minutes.

A wide variety of related books are also available, for instance on bridge demolition.

6011. Open Sources and Radio Detonation of Bombs

Apart from simple explosives, it merits comment that sophisticated devices for detonating explosives from a distance are readily available to criminals and terrorists.

Bombs can be detonated by remote control, through radio detonation. The chip needed for production of the detonating tone retails under $20.00.

A book entitled *Improvised Radio Detonation Techniques* describes how to modify various types of radio equipment into detonation transmitters. This slide lists devices afforded a chapter in the book, along with relevant information regarding their modification.

In March, 1994, this book was among numerous other books found in a storage locker of a man suspected in the package bomb that killed five people in upstate New York. In a similar incident, on February 10, 1995, the Associated Press released a report of a high school student's locker booby-trapped with a set of firecrackers wired to a circuit board and capable of being detonated by radio control.

Radio detonation, including that of car bombs, is a major problem worldwide:

-- In May 1992, the Mafia killed Judge Giovanni Falcone and three bodyguards with a car bomb detonated by remote control while they were driving along a Sicilian highway.

-- A March 1994 article in the Current Digest of the Soviet Press entitled "Who's Getting Killed In Moscow, and How" cited the problem of remote control detonation.

-- In January 1995, a group that manufactured radio detonated bombs was arrested in St. Petersburg. Constructed for $60 and sold for $1,500, the bombs came with a six month guarantee.

According to the Intelligence Newsletter of March 16, 1995, Egypt spent $18 million in 1994 on equipment to detect car bombs and to jam their detonation frequencies.

6012. Open Sources and Vehicular Enhancements

Evasion is a significant concern after executing an operation. There are a number of enhancements that can be made to vehicles, enhancements which can increase chances of evasion if detected and pursued. Some possible enhancements are listed in this slide.

There is a thriving small industry specializing in the production of armored cars for civilians. Publications such as *The ROBB Report* routinely advertise all manner of armored vehicles for sale--vehicles which to all outward appearances, are simply a normal car.

In addition to enhancements to the individual vehicle, skill at evasive driving is crucial in case operatives are detected. One manual on evasive driving illustrates evasive techniques on city or country roads, and in chase situations, along with automobile security modifications such as an oil slick or smoke screen generator. In case the driver does not successfully evade the pursuer, techniques for knocking the pursuer off the road are described. The manual has a chapter entitled "Suggested Training Schedule."

This is a good point in the chapter to emphasize that criminals and terrorists are very aware of the fact that they pursue very high-risk, high-gain occupations, and have a great deal to gain from proper preparation. Their preparations are all the more difficult to deal with because by definition they are camouflaged as civilians and do not wear uniforms or follow any recognized rules of engagement. Establishing their technical capabilities and their "order of battle" thus calls for entirely different collection methodologies.

6013. Open Sources and Tactical Communications Jamming

Military forces rely heavily on command & control, and on combined arms operations. Military patrols in support of law enforcement operations are relying on artillery and other forms of reinforcement as they venture out "on point". It therefore becomes important to understand that criminals and terrorists are capable of executing tactical communications jamming operations.

Although radio jamming is illegal, *Improvised Radio Jamming Techniques* is a technical book describing the construction of a jamming station, allowing an operative to jam radio transmissions of government agencies as part of an operation or during the evasion stages.

Chapters in the book include:

-- Intercept Equipment Selection
-- Covert Antenna Systems
-- Intercept Operations
-- Police Radio Operational Procedures
-- High-Risk Frequency Detection Techniques
-- Jamming Equipment Deployment
-- Operational Security

6014. Open Sources and Bank Card Forgery

Central to criminal and terrorist operational security is the creation of a new identity, or a variety of identities that frustrate the efforts of law enforcement officials to track their international and domestic movements. The methods of creating a new identity in various books range from obtaining a new public image to physically disappearing and altering one's identity. Some books on creating a new identity focus on obtaining public records under a new name. Chapters are devoted to social security cards, driver's license, credit cards, and bank statements.

Other books exist on how to produce counterfeit identification documents. One book contains chapters such as The Forger's Kit, Forgery Techniques, and Quality Control, and discusses the "False Identification Crime Control Act of 1982" which prohibits selling fake I.D. by mail. The book continues: "It's still possible for the forger to buy the various

materials needed to produce fake I.D." and provides names and address and several companies.

A separate book exists devoted to counterfeiting currency. Chapters include "Basic Printing Techniques Used in Counterfeiting," " Purchasing Equipment and Supplies," and "Passing Counterfeit Currency."

Worldwide contacts, and world-wide mail drops, area readily available to criminals and terrorists. Companies publish booklets listing lawyers, bankers, and accountants in numerous countries ready to take a call from someone in need, together with lists of thousands of companies providing voice, fax, and correspondence forwarding services.

These are the traditional methods. Today, "cyber-theft", and direct anonymous access to bank accounts, as well as the complete concealment of international financial transactions through encryption and anonymous remailers, is becoming the major foundation for global criminal activity. One good reference is *Electronic Fund Transfer Systems Fraud*, published by Paladin Press (ISBN 0-87364-490-5).

6015. Open Sources and "Legal" Offshore Passports

Companies will, for a fee, arrange a legal passport and citizenship for their client, from a country not the person's country of birth.

Below is the fee scale from a company based in Amsterdam which specializes in passports and citizenship from Latin American and Caribbean countries--a legal citizenship with can be obtained within 90 days of submitting the company's application.

Dominican Republic	$19,500 for 1-4 individual orders
Venezuela	$21,900 for 1-4 individual orders
Panama	$20,900 for 1-4 individual orders
Ecuador	$23,900 for 1-4 individual orders

The application requests information such as the applicant's name, date and country of birth, height, eye color, visible scars, existing citizenship, profession, and mother's maiden name.

Along with the application, one need submit:

-- the signature and photo page of the applicant's current passport
-- copy of a birth certificate
-- three color negatives in three different sets of clothing
-- affidavit of good conduct from a licensed attorney or local police clearance
-- six thumbprints
-- six signatures on a white sheet of paper

-- a personal character reference or bank reference

The company's material explains that one need not visit his new country but can remain a "citizen living abroad," and contains a chart indicating countries that can be entered without a visa with your new passport.

The company can arrange a diplomatic passports "to some," for a fee of $55,000.

A midwest American company offers "genuine" passports and driver's licenses from countries that no longer exist, such as Burma, Rhodesia, Dutch Guiana, and the Republic of Zanzibar. The company portrays these passports as "emergency passports," in case terrorists hijack a plane and the American traveller would not want to identify himself as such. The application requires only a name and credit card number.

A U.S. Government "Passport Agent's Manual" has been acquired and republished by a commercial publisher. The manual is a useful guide for avoiding obvious mistakes.

6016. Open Sources and Offshore Corporations

In addition to arranging second passports and citizenship, companies exist that will establish shell companies for their client, generally offshore.

One British company specializes in establishing companies in the Bahamas, Belize, the British Virgin Islands, Delaware, Gibraltar, and Panama. The company's promotional material contains a chapter on each country, reviewing the requirements regarding:

-- capital and shares
-- directors and shareholders
-- meetings
-- accounting
-- corporate seals
-- company name
-- registered agent, office, and domicile

The application form requests only the name of the company to be established, the names and nationalities of the shareholders and directors, the objective of the company, and the applicant's name and address.

A Hong Kong company will also form a company in numerous localities around the world, from the Cayman Islands in the Caribbean to the Isle of Man located in the Irish Sea. The company's specialty however is Hong Kong "shelf companies"- corporations ready for purchase.

The Hong Kong company provides a list of over one hundred shelf companies incorporated in Hong Kong. Company names were chosen, apparently with the intent of attracting American buyers. These shelf companies were incorporated in 1993-94, allowing the company's purchaser to give the impression that the company had been in business years before the purchaser took control.

The application form requests only the names, business occupations, nationalities, and passport numbers of the company's officers and directors, along with information on the purchaser's bank account. For the client's benefit, the Hong Kong company includes educational material on how to arrange letters of credit through the client's new offshore company.

6017. Open Sources and Choosing a Criminal Specialty

Similar to books on individual methods and techniques, books are available on crime as a profession. For example, a book entitled *Drug Smuggling* contains information on how to find a drug source, what type of airplane is suitable for smuggling, and how to launder money. It closes with a discussion on dealing with law enforcement and a chart detailing federal and state drug laws, shown in this slide.

A book entitled *Successful Armed Robbery* written by an inmate in a federal penitentiary, contains the following chapter headings:

-- The Selection Process
-- Strategic Production-Planning
-- Factors Affecting Your Success
-- Self-Caused Failure

This book contains diagrams of various types of parking lots and illustrations on how to approach and assault the driver of a car.

Hit Man; A Technical Manual for Independent Contractors covers the entire range of activity for the planning and execution of a contract murder. Topics range from surveilling the target to psychological approaches to the job. From a chapter entitled "Finding Employment, What To Charge, Who To Avoid": "Prices vary according to risk involved, social or political prominence of the victim, difficulty of the assignment, and other factors. A federal judge recently brought the price of $250,000, according to one example provided. A county sheriff might bring $75,000 to $100,000."

A related book entitled *How To Hide Anything* is available to criminals and terrorists. It contains numerous diagrams illustrating the construction of hiding compartments for objects or people an indoor and outdoor settings, and can be used to create hiding places for contraband, documentation of illegal exchanges, and special illegal technical equipment.

The list goes on. There is a market in information about how to be a criminal or terrorist, and there are established concepts, doctrines, and information about organization, methods, and equipment which is readily available world-wide.

6018. Conclusion: The Dark Side of Open Sources

This chapter has reviewed the open source knowledge available to criminals and terrorists which, when properly utilized, can make the military mission and the mission of law enforcement more difficult.

In particular, this chapter has sought to emphasize that operational security and the "need to know" are important aspects of success against a well-trained and well-equipped criminal or terrorist organization which understands the value of intelligence collection.

Criminals and terrorists can intercept radio and telephone conversations; they can exploit eavesdropping devices and execute tactical signal intelligence collection operations. They know how to conduct undercover operations, how to interrogate captured prisoners, and how to do direct research using open sources.

Individuals can be effective at executions and in the use of explosives. Radio detonation of explosives through a variety of remote devices is easily understood and readily carried out.

In the escape and evasion phase, criminals and terrorists can exploit armored vehicles equipped with oil slick and other devices for delaying pursuit, and can also execute tactical jamming operations which may allow them cut off and surround their military or law enforcement pursuer before back-up forces can be mobilized.

In conducting transnational criminal and terrorist activities, these individuals can avail themselves of false credit cards, new identities including legal passports possibly obtained through false supporting documentation, and related corporate and letter of credit documentation.

Over all, this chapter has sought to communicate the degree to which information about various criminal professions is available in the open source world, allowing for knowledge about how to conduct many different kinds of crimes and illegal activities to pass from one generation of criminals to another.

Criminals and terrorists can think and read--open sources are as useful to them as they are to intelligence professionals and the operational commanders they support.

Chapter 7

CONCLUSION: COLLECTING AND PROCESSING OPEN SOURCE

7001. Purpose of the Chapter

This final chapter wraps up the handbook by providing information about three official U.S. government channels for obtaining open source intelligence: the Community Open Source Program Office and its global Open Source Information System; the Defense Intelligence Agency Open Source Program and the (planned) Defense Intelligence Agency Open Source Intelligence Center; and--especially important for Marines--the Marine Corps Intelligence Activity and the Expeditionary Factors Study. The Chapter concludes with a brief discussion of the usefulness of the Marine Corps Reserve as a source of existing and new open source exploitation experts, and some recommendations on additional open source training opportunities.

7002. Community Open Source Program Office

The Community Open Source Program Office (COSPO) was established effective 1 March 1994 by DCID 2/12, which superceeded the earlier establishment on 1 June 1992 of the Open Source Coordinator. The requirement for an Open Source Coordinator first emerged in 1992 as a result of the findings of the Open Source Task Force, one of eleven task forces that Congress required the Director of Central Intelligence to establish as part of his confirmation process. Although all elements of the Intelligence Community have used External Research & Analysis (ER&A) funds to contract for academic and technical research, and the Foreign Broadcast Information Service (FBIS) of the Central Intelligence Agency has been responsible for monitoring foreign print media as well as radio and television broadcasts, the task force concluded that a focal point would be helpful to the DCI.

According to DCID 2/12, "The COSPO is responsible for the definition and defense of the Open Source Program in the planning cycle, and for providing guidance and oversight to the program in the execution cycle. The Office, with Community departmental open source program managers, develops an optimum allocation of resources across the Community in the execution year, subject to ratification by the Open Source Steering Committee. ... the objectives of COSPO are to:

a. Oversee a process for coordinating responsive actions to satisfy user needs.

b. Provide advocacy and defense of departmental development and operational efforts.

c. Ensure funds for critical open source activities.

d. Oversee a process for identifying and prioritizing open source substantive requirements."

COSPO functions include strategic planning, program formulation and representation, initiative and innovation sponsorship, operational services of common concern, systems architecture, development of services of common concern, and open source advocacy and representation.

Speaking publicly to the annual international conference on open source intelligence, in 1995 Dr. Joseph Markowitz, the Director of COSPO, stated that roughly 40% of the all-source product funded within the National Foreign Intelligence Program comes from open sources, at a cost to the program of only 1% of the total budget. Experts generally agree that the percentage of the open source contribution will vary from zero to 100 percent depending on the problem, and than an average of 40-60% is readily certifiable. Somewhat unexpectedly, open source receives great credit against terrorism and proliferation, and is said to account for as much as 80% of the all source product in those two reporting areas.

7003. Open Source Information System

The Open Source Information System (OSIS) is the principal means by which COSPO is seeking to enhance analyst access to open sources. However, as it is limited at this time to information available in electronic form, it must be regarded as a very positive but only partial solution.

OSIS is an electronic network which provides both access to and sharing of unclassified U.S. Government and other open source information about Intelligence Community (IC) agencies and selected other organizations with similar information requirements.

OSIS is being installed at the various Joint Intelligence Centers, and should one day be accessible to any Marine Corps intelligence professional afloat or ashore. Examples of the information available in OSIS include:

-- Jane's Electronic Library of 24 titles providing up-to-date information on military equipment, weapon systems, and defense products worldwide

-- IC ROSE, a database service providing fulltext articles from hundreds of periodicals on a wide range of subjects

-- FBIS products online, including the Daily Reports, S&T Perspectives, Trends, and Pacific Rim Economic Review

-- Oxford Analytica Regional Daily Reports (Strategic Political and Economic Intelligence)

-- DTED, the Defense Mapping Agency's online Digital Terrain Elevation Data map collection providing worldwide coverage

-- CIRC, a database of over ten million titles on scientific and technical topics, including patents, standards, military equipment, and systems

-- a Conference Database of upcoming symposia, congresses, conventions, etcetera, in the areas of science, technology, engineering, politics, and economics

-- Unclassified library holdings of several OSIS member agencies including DIA

OSIS also offers specialized tools, such as the National Air Intelligence Center's SYSTRAN machine translation capabilities to support real time translations of non-English language information located on World Wide Web sites.

7004. Defense Intelligence Agency Open Source Program

The Program Manager for Open Source Intelligence within the Defense Intelligence Agency is Ms. Alice Cranor, whose contact information is provided here. She serves as the DIA representative to the Open Source Council, which is the advisory body formed to support the Community Open Source Program Office (COSPO). Each agency and service has a single representative to the Council. In addition to an agency-level focal point, every branch within DIA has an OSINT focal point.

Ms. Cranor, whose office code is PO1-3, can be reached by voice at (202) 373-4005, via facsimile at (202) 373-8971, or via email at <AFcraat@dia.osis.gov>.

MAGTF OSINT requirements should be discussed with the appropriate DIA Branch OSINT focal point to ensure that existing DIA capabilities for accessing OSINT on that topic are not overlooked.

7005. Defense Intelligence Agency Open Source Intelligence Center

As of August 1996, a new initiative is under discussion, to create a DIA OSINT Center funded at $10 million a year, and consisting of an EAGLE VISION ground station (to receive commercial imagery directly from commercial satellites), close to $3 million a year to buy commercial imagery not obtainable through Defense Mapping Agency funding, and $4 million a year to fund roughly 4,000 man-days of individual international expert support for the entire defense intelligence community. Although not yet approved, this initiative has been favorably discussed by the Director of DIA with Congressional staff, and funding is anticipated. MAGTFs should be developing their open source requirements and submitting them through appropriate channels to ensure that a fair share of these resources are devoted to expeditionary intelligence requirements.

7006. Marine Corps Intelligence Activity

The Marine Corps Intelligence Activity (MCIA) has from its inception understood and valued open source intelligence. Today the primary expression of Marine Corps emphasis on the value of open source is the Expeditionary Factors Study, discussed below. In addition, MCIA has a Mapping, Charting, & Geodesy section which is able to acquire and exploit commercial imagery in support of MAGTF requirements, and all analysts are aware of the value of open sources for fulfilling expeditionary intelligence requirements.

The MCIA Librarian, Ms. Barbara Necoba, is the focal point for Marine Corps OSINT requirements.

7007. Expeditionary Factors Study

In 1988, when the Marine Corps Intelligence Activity (MCIA) was first established, the first Director (a Colonel) and his civilian Special Assistant/Deputy Director discovered that much of what was needed by the Warfighting Center, the acquisition program managers, and senior staff at Headquarters Marine Corps, was not available through classified databases and classified intelligence products. In close consultation with the Fleet Marine Force, MCIA established an agreed upon list of 67 countries and two island groups against which to develop encyclopedic intelligence. Working closely with the Warfighting Center, a wide variety of mission area factors were agreed upon, and defined by the operators in terms of five levels of difficulty. Under the supervision of the Special Assistant/Deputy Director, a contractor was hired to prepare Overview of Planning and Programming Factors for Expeditionary Operations in the Third World. This three-volume product was approved by the Commanding General of the Marine Corps Combat Development Command for dissemination in March 1991, and represents the Marine Corps' ground breaking effort to create a useful intelligence product using only open sources.

Subsequently Marine Corps flag officers were consulted and agreed on a new list of 80 countries, and the study was repeated, now titled Expeditionary Force Mission Factor Intelligence Analysis Requirements Study (ExFac Study), and this new expanded study was published 15 September 1994 in both hard-copy and as a CD-ROM database. There are over 100 copies of this unique resources available throughout the Marine Corps, with one set in the library of the Navy Marine Corps Intelligence Training Center.

The following mission area factors are covered for each of 80 countries (Appendix H contains a list of the countries):

Drug Threat	Ground Order of Battle
Terrorism	Air Order of Battle
Gray Arms & Technology Transfer	Naval Order of Battle
Nuclear, Biological, & Chemical	Ongoing Conflicts
U.S. Equities	Culture

Weather	General Geographic Conditions
Coastal Characteristics	-- Cross-Country Mobility
Mapping. Charting, & Geodesy	-- Intervisibility
Airfields	-- Operational Elevation
Ports	Key Installations
Noncombatant Evacuation Logistics	Communication Infrastructure
Highways/Railways	Medical Operations

Examining the results contained in this study leads some very useful "strategic generalizations" which can help planners better prepare for expeditionary operations. For instance, the Marine Corps aviation day is hot, over 80 degrees on average, with relatively high humidity. Fewer than 50% of the ports in the this Marine Corps environment are suitable for pierside offload, requiring instream offload even when unopposed. Intervisibility (line of sight) distance in much of the Marine Corps world is heavily constrained, and cross-country mobility is almost non-existent. It should be stressed that this unclassified intelligence product is for orientation and ready reference purposes, it should not be used as the basis for planning and conducting military operations--it provides context and is intended to aid in requirements analysis and collection management of the traditional disciplines.

Every MAGTF should have at least one copy of this study, available in both hard-copy (three volumes) and CD-ROM. To obtain a copy, communicate with Mr. Steve Foster, Deputy Director, MCIA, at (703) 784-6140.

7008. Marine Corps Reserve

The Marine Corps Reserve represents a very significant source of open source expertise. Many Marine Corps Reserve personnel have achieved considerable stature as civilian experts in various regional and subject matter areas. Many have worked overseas as civilians, and acquired foreign language and foreign culture expertise which may not be a matter of record but which qualify them as "virtual" Foreign Area Officers.

MAGTFs should consider initiatives to identify specific Marine Corps Reserve personnel competent in languages and countries of direct interest to the MAGTF, so as to hold these Reservists as "hip pocket" augmentation unit for specific contingencies. As a general rule, the reservists who are most talented and most competent will not be available for "make work" active duty assignments or Individual Mobilization Augmentee billets, but would be available for 15-30 assignments in their country of interest.

Such reservists can be requested and funded apart from the normal Marine Corps Reserve funding process, by requesting General Defense Intelligence Program (GDIP) Reserve Augmentation funding from HQMC. When requesting orders for such reservists, ensure that the request specifies that a) liberal civilian grooming and attire authorized; b) non-reporting orders; and c) special conveyance authorized. The first permits the Reservists to blend in as civilians as they "walk the ground" legally; the second avoids any unnecessary

contact with the U.S. Embassy and precludes the Reservists from being co-opted for administrative duties by the local defense attache; and the third permits them to take in-country tours with guides, as well as hire canoes, donkeys, and other conveyances requiring an indigenous driver.

7009. Additional Open Source Training Opportunities

There is only one significant private sector source of open source intelligence training expertise, and that is OPEN SOURCE SOLUTIONS, Inc., the non-profit educational corporation dedicated to studying and teaching open source intelligence. This organization offers three significant additional open source training opportunities:

a) Annual Conference. Each year in mid-September, OSS, Inc. offers a 3.5 day conference on open sources, systems, and services. This conference, the only one of its kind, attracts between 600-800 international representatives (although 50% of the audience is from the U.S. government), and includes the Open Source Coordinators for all of the major European nations as well as many Asian and African nations. For information about the conference send electronic mail to <OSS96@oss.net> (change year as appropriate); send a facsimile request to (703) 242-1711, or call (703) 242-1700 and leave a complete mailing address.

b) Newsletter. *OSS NOTICES* is the only newsletter in the world dedicated exclusively to open source intelligence, and it draws on a substantial range of other publications to report each month, in 30-40 pages without advertising, on open sources, systems, and methods. Each month's issue has a theme, including six regional themes a year. To review past issues, visit <http://www.oss.net/oss>, email <oss@oss.net> with a request for a sample copy, or fax (703) 242-1711 with a request and complete mailing address.

c) References. OSS, Inc., which is now entering its fifth year as the leading advocate and student of open source practices, publishes a two volume *Proceedings* from each of its annual conferences, and these are available for purchase. Especially recommended is the set from 1995, which consists of *Open Source Intelligence: Selected Readings* (Volume I) and *OSS '95: The Conference* (Volume II).

The Community Open Source Program Office has in August 1995 released a Request for Proposal for a series of training lessons oriented toward the Open Source Information System, and these will be available no earlier than 1998 and perhaps later.

Any questions? Mr. Robert D. Steele, President of OPEN SOURCE SOLUTIONS, Inc., and a former Marine, is prepared to support any MAGTF in any clime and place. Communicate with him at <ceo@oss.net>, voice: (703) 242-1700, or fax: (703) 242-1711.

APPENDIX A

Open Source Intelligence: What Is It? Why Is It Important to the Military?

Robert D. Steele, President
OPEN SOURCE SOLUTIONS, Inc.

Introduction

This White Paper defines Open Source Intelligence (OSCINT) and its relevance in meeting the needs of the military (both commanders and defense policy-makers).

OSCINT is intelligence derived from public information--tailored intelligence which is based on information which can be obtained legally and ethically from public sources.

This White Paper suggests that OSCINT is a both force multiplier and a resource multiplier. OSCINT provides a practical political and military advantage which complements the advantage provided by traditional intelligence, it is available at low cost, and it cannot be ignored.

First the paper describes and discusses the utility of OSCINT in general terms, and at the strategic, operational, tactical and technical levels of warfare, including a single practical example at each level. The paper then describes the "information continuum" within which a range of open sources, systems, and services can be obtained which are relevant to military needs. Finally, the paper provides a brief discussion of the status of the open source intelligence programs in the United States, The Netherlands, and Sweden, and concludes with a concise discussion of opportunities and risks inherent in the use of OSCINT to meet military requirements, and of several practical steps that can be taken to exploit OSCINT in support of military strategy, operations, tactics, and technical acquisition and countermeasures.

The official definition of OSCINT by the U.S. Intelligence Community:

> By Open Source we refer to publicly available information appearing in print or electronic form. Open Source information may be transmitted through radio, television, and newspapers, or it may be distributed by commercial databases, electronic mail networks, or portable electronic media such as CD-ROM's. it may be disseminated to a broad public, as are the mass media, or to a more select audience, such as gray literature, which includes conference proceedings, company shareholder reports, and local telephone directories. Whatever form it takes, Open Source involves no information that is: classified at its origin; is subject to proprietary constraints (other than copyright); is the product of sensitive contacts with U.S. or foreign persons; or is acquired

through clandestine or covert means.[1]

The official definition is limited in its understanding to standard commercial sources of traditional information, and excludes, to take one important example, SPOT imagery. It also fails to take into account the importance of unpublished materials including electronic information and human knowledge which can be accessed legally and ethically.

The official approach to OSCINT is also limited in that the existing information-handling architectures for intelligence processing, including dissemination to the commander, are all classified, and there is a very limited capability for routing unclassified information efficiently, even assuming it can be obtained. In most communities, there appears to be a reluctance to assume primary responsibility for the collection and processing of OSCINT, which is why military operators in two countries (the United States and the United Kingdom) are examining means of acquiring and exploiting OSCINT directly, bypassing the intelligence community in order to give action officers at the policy level, and commanders at the operational level, direct access to OSCINT.

Experienced intelligence professionals have found that while OSCINT is not a substitute for traditional intelligence disciplines, including Human Intelligence, Imagery Intelligence, and Signals Intelligence. However, OSCINT does offer three major advantages for planning and conducting military operations:

-- When encountering requirements for military operations in the Third World or in support of humanitarian assistance and counter-terrorist operations for which intelligence collection priorities have not been high. OSCINT is frequently the only discipline able to respond rapidly (to include commercial imagery), and it provides the commander and his staff with a rapid orientation adequate for both developing initial planning packages; and for establishing collection requirements for the traditional intelligence disciplines.

-- OSCINT is also a means of achieving significant savings, in that many essential elements of information required by the commander and his staff can be acquired from commercial sources at a lower cost, in less time, than from classified capabilities, with the added advantages that OSCINT is often more up to date, and requires no political risk in its acquisition. *This permits classified intelligence capabilities to be focused quickly and effectively on mission-critical gaps, and avoids depleting or mis-directing these scarce resources—"do not send a spy where a schoolboy can go".*

-- Finally, OSCINT, whether it precedes or follows traditional intelligence collection, can protect national intelligence sources and methods by serving as the foundation for

---

[1] Although the original intelligence community report was classified SECRET, the definition and extensive commentary appeared in an unclassified document, *United States Marine Corps Comments on Joint Open Source Task Force Report and Recommendations (Working Group Draft Dated 6 January 1992)*, and portions, including the definition, were subsequently reprinted in *OSS NOTICES* Volume 2 Issue 9 (30 November 1994).

intelligence support to joint and coalition operations where it is not possible, or desirable, to reveal the capabilities and limitations of the traditional intelligence community.

Open Source Intelligence and the Military

The availability and utility of OSCINT depends upon, and will vary, depending on the specific area of operations under consideration, and on two other factors: the level of warfare, and the point on the spectrum of conflict, from presence to general war, where the intelligence will be applied.

In general terms, OSCINT has significant potential as a source of intelligence support in terms of indications & warning, policy development, contingency planning, security assistance, weapon acquisition (design and countermeasures), joint and coalition operations, and tactical operations against new priorities such as proliferation. Finally, OSCINT is vital as a means of rapidly orienting the commander and serving as the foundation for collection management within the traditional intelligence disciplines.

At the strategic level:

-- OSCINT can provide indications & warning of both hostile intent, and opportunities for military advantage. Content analysis of multiple open sources such as regional newspapers from the Middle East, are often if not always more reliable foundations for estimating stability and instability, than reports from clandestine sources with a limited range of access and a personal perspective that biases their reporting.[2] OSCINT is especially valuable with respect to cultural and demographic intelligence, areas not generally well-covered by traditional civilian and military intelligence collection and analysis capabilities.

-- OSCINT can also provide very important geographic and civil generalizations which can significantly affect major military acquisition and design decisions. For instance, most countries build their aircraft for optimal performance on a "standard aviation day" which is defined in terms of warm (60°-70°F) conditions and balanced humidity. The military commander that is responsible for expeditionary operations to the Third World will find themselves utilizing aircraft which carry half as much half as far because the standard aviation day in the Third World is hot (over 80°F with high humidity). If aircraft cannot be designed for optimal performance on a hot day, then the military commander can at least ensure that doctrinal publications reflect accurate load and lift capabilities for the true expeditionary conditions to be encountered.

-- OSCINT can provide unclassified threat intelligence which can be used to educate

---

[2] This point was made publicly by Dr. Stephen Fairbanks, the Iranian Analyst for the U.S. Department of State's Intelligence and Research Bureau, in the presence of his superior, Dr. Jennifer Sims, Deputy Assistant Secretary of State for Intelligence Coordination.

and mobilize public and political support for military needs including policy development.

At the operational level:

– OSCINT can provide the geographic and civil generalizations required for regional force planning and force employment. In particular, OSCINT has establish credible regional generalization regarding the capabilities of air, ground, and sea forces to be encountered by the commander; geographic generalizations with respect to cross-country mobility, average line of sight distances, temperatures, and water availability; and civil generalizations such as bridge-loading, port clearance, airhead bunkerage; and civil communications and computing resources. OSCINT provides a time-sensitive solution to questions the theater commander will have about civil infrastructure, political cliques and personalities, and economic or financial factors affecting operational employment of forces, and is therefore especially helpful to contingency planning which must be pursued without adequate support from traditional intelligence capabilities.

-- OSCINT is especially useful to the theater commander for the coordination of joint and coalition operations where traditional classified intelligence capabilities are either not available (e.g. in much of the Third World where lower priorities have restricted coverage), or cannot be shared with foreign elements.

At the tactical level:

-- OSCINT has been shown to be highly pertinent and effective against new priorities, including counter-proliferation, counter-terrorism, and peacekeeping operations. This is true for both conventional military operations focused on overt interdiction, and clandestine or covert "direct action" by special operations forces.[3]

-- OSCINT is a critical resource for the military commander who requires maps and digital targeting information for Third World area for which current geographic information is not available from government sources, whether classified or unclassified. In combination, SPOT and other commercial imagery resources can provide the commander with up to date maps containing all airfields, roads, and bridges; and soon containing contour lines as well,

---

[3] At a Canadian intelligence conference 27-29 October 1994, both the Director of the Canadian Security and Intelligence Service, Mr. Ward Elcock; and Dr. Paula Scalingi of the Los Alamos National Laboratory in the United States, stated that OSCINT provides over 80% of the input to the final all-source product; in Dr. Scalingi's case, this was with specific reference to intelligence support for counter-proliferation. Dr. Gordon Oehler, Director of the U.S. Intelligence Community's Nonproliferation Center, has made similar comments on several public occasions.

for expeditionary operations.[4]

At the technical level:

-- OSCINT about civil communications and computing capabilities in the area of operations will be very important to the commander. As information warfare and information peacekeeping become critical mission areas, and all opponents achieve some capabilities to conduct electronic warfare, the commander will need to use OSCINT both to understand how to degrade the performance of civil capabilities being used by opponents, and to consider exploitation of civil capabilities to maintain joint and coalition communications.

-- OSCINT will provide most of what the commander needs to plan and coordinate joint and combined air, sea, and land operations in the expeditionary environment, with specific reference to strategic airlift and sealift operations involving civil aircraft, air traffic control and air defense planning for civil platforms, and fueling and other logistical considerations.

The Information Continuum

There are three ways of understanding the robust nature of the private sector's potential contribution to military intelligence needs. The first is by examining in general terms this continuum.

		Private Investigators		
Schools	Libraries	Information Brokers	Government	Intelligence
Universities	Businesses	Media	Defense	

Each of these nine sectors of the global or national information community maintains a cadre of human experts as well as a range of both hard-copy and electronic information. Much of what is known to them, or stored by them, is not available through commercial online services. Following a specific example from each sector:

---

[4] SPOT is going to 5-meter resolution imagery in the very near future. In the U.S. Space Imaging, Inc., a subsidiary of Lockheed, has announced plans to provide 1:2,500 meter synoptic resolution imagery, within a year. These commercial capabilities will be critical to expeditionary operations in the Third World because of the lack of current maps. One U.S. study, *Overview of Planning and Programming Factors for Expeditionary Operations in the Third World* (Marine Corps Combat Development Command, March 1991), determined that for the 69 countries of concern to the Marine Corps, there were no 1:50,000 combat charts for 22 of the countries, old 1:50,000 charts for ports and capital cities only in the case of another 37 countries, and very old 1:50,000 complete coverage for another ten countries.

-- Language schools can rapidly identify individuals by location and nationality who have received training in the home country language and are target country nationals (e.g. Somalis studying French in Paris): these individuals can be contacted and offered part-time employment as translators.

-- Universities utilize their existing infrastructures and a regular supply of cheap intellectual labor to maintain important and authoritative databases. The Monterey Institute of International Studies, for instance, maintains the best database on the proliferation of nuclear materials, and utilizes graduate students fluent in Russian, Chinese, Arabic, and other languages to cover a wide range of multi-lingual publications, and to maintain an electronic database, at very low cost.

-- Libraries can be used, either as needed or in a deliberate fashion, to serve as repositories for "just in case" archiving of political-military, economic, and other materials pertaining to specific countries. This allows the government to share the cost of archiving with other library sponsors, and in many cases avoid the cost all-together.

-- Businesses have enormous repositories of market research, including communications and logistics research, on countries throughout the world where they have made or plan to make an investment. Businesses are also acutely familiar with the political corruption, climate conditions, and other factors which affect operational efficiency in specific locations. Two unique examples of business dedicated to meeting private intelligence needs are Oxford Analytica, with its network of 750 overt agents world-wide, and *The Economist* Intelligence Unit.

-- Information brokers can be identified who specialize in particular scientific & technical topics or regions of the world. This permits more efficient search & retrieval by exploiting capabilities whose "learning curve" has been funded by others. In addition, information brokers can be identified with specific language capabilities, and employed to do rapid exploitation of captured or acquired documents.

-- Journalists responsible for specific areas of the world, including journalists specializing in military, aerospace, and insurgency matters, rarely publish ten per cent of what they know, and they never publish their sources. They can, however, be engaged to prepare special reports, and to provide background information on specific personalities of importance to planned military operations. This need not be done secretly or through direct recruitment; it can be done discreetly as a private commercial transaction. Media organizations, such as Jane's Information Group, acknowledge that they publish less than 20% of what they know, in some cases to protect sources--they are however willing to do tailored confidential reports drawing on their complete range of sources.

-- Governments, including provincial and state governments, frequently have experts in agriculture or other trade-related fields who are familiar with specific areas of operation and the logistics as well as the key personalities. Embassies have personnel whose reporting

does not fully communicate what they know. Bringing key government personnel together for a week can quickly establish a foundation for collection management which the commander could not normally achieve through analysis of raw information.

-- Other intelligence organizations, including the "information and research" elements of the Vatican, the United Nations, and the International Red Cross, have global networks of reporting sources, including sources with special linguistic and regional skill, that can be drawn upon.

The third way of understanding the robust capability of the private sector is to consider the range of information services that are offered which are directly pertinent to military intelligence needs. These are listed in three columns:

Direct Observation	Document Acquisition	Telephone Surveys
Commercial Online Searching	Document Translation	Market Research
Current Awareness	Broadcast Translation	*Recruited Agents*
Experts On Demand	Multi-Expert Research	*Industrial Espionage*

Recruited agents and industrial espionage are not considered legal nor ethical within the private sector, but there are very competent organizations that openly offer such services, to include route reconnaissance and target identification services in third countries. In each of the above categories, it is highly likely that a private sector partner can collect, process, translate, and deliver open sources of intelligence able to make an important contribution to the commander's needs for information--and to do so in a cost-effective fashion which could not be duplicated by defense attaches or traditional military intelligence collection brigades.

The third way to understand the utility of the private sector for military intelligence needs is to take a case study, such as Somalia. In the absence of internally-available intelligence information, the fastest means of establishing an encyclopedic foundation for further collection management, and the fastest means of providing the commander with at least some useful information pending responses from the traditional intelligence disciplines, it by seeking out private sector experts and private sector databases. A leading scholar, a leading businessman recently returned from a tour as General Manager in Somalia, a leading journalists, and perhaps an information broker specializing in African information could be brought together and could quickly identify human, hard-copy, and electronic sources--including sources of digital geographic information--of immediate utility.

In one specific instance, supporting a wargame on Somalia, an individual playing the role of the United Nations commander was able to overcome the inadequacies of the U.S. intelligence community by making three telephone calls. Overnight, in Express Mail, at a *pro forma* cost of about $5,000, the individual received:

– From Jane's Information Group, a spiral-bound volume containing a map of Somalia clearly marking the nine clan areas; a one-page order of battle for each clan (at a time when most intelligence analysts were thinking only of the old Somali army); and a one-paragraph precis with full citation for each article about Somalia published in any of the Jane's publications (including the excellent *Jane's Intelligence Review*) in the past two years. This constituted a superb orientation for both planning and collection management.

– From Oxford Analytica, twenty two-page reports suitable for Presidents and Prime Ministers, covering three topical areas: United Nations operations in Somalia, U.S. foreign policy toward Somalia; and U.S. operations related to Somalia. Again, a superb orientation on strategy and policy, in concise and immediately-usable form.

– From *The Economist* Intelligence Unit, a copy of the appropriate country risk report, which included important summary information on the logistics difficulties that would be encountered, including the limitations of both the port and the airfields for strategic entry.

Commentary on Representative National Approaches to OSCINT

Although OSCINT has always been part of the national and military intelligence process, in recent decades increased emphasis on technical systems and secret collection have tended to sharply reduce the amount of funding and the number of personnel dedicated to collecting and processing publicly available information. At the same time, the "information explosion" or "information revolution" has dramatically increased both the quality and quantity of the information available in the public sector. Today the commander can take a weather map of Bosnia off of the Internet, or exchange email with volunteer observation and listening posts in Bosnia.

Unfortunately, the reality today is that most intelligence communities are trained, equipped, and organized to collect and process secrets. OSCINT capabilities in both the civilian and military sectors of government have both atrophied where they existed, and also failed to keep up with the growth of private sector OSCINT capabilities.

– United States of America. The National Foreign Intelligence Board was recently briefed to the effect that while 99% of the $28-35 billion dollars a year budget is spent on classified collection and processing, and only 1% is spent on OSCINT, OSCINT provides 40% of the all-source product. In one interview, the Deputy Director for Science & Technology of the Central Intelligence Agency stated that this latter figure was actually 70%. The major element of the U.S. intelligence community program is the Foreign Broadcast Information Service, which is under severe criticism for its continued emphasis on print

media exploitation, and its inability to master a wider range of open sources. In an attempt to gain control over the modest distributed resources being applied to OSCINT, the Director of Central Intelligence created the Community Open Source Program Office. This office is about to release a strategic plan for OSCINT, but it is limited to improving internal community access to open sources already collected. The Department of Defense program. for which the National Air Intelligence Center is the executive agent, builds on the existing scientific & technical intelligence document acquisition and translation program. The Department of Energy Laboratories, and especially Sandia and Los Alamos, constitute a major OSCINT resource which is being exploited by some military consumers of intelligence, such as the U.S. Southern Command, but which is not under the control of the intelligence community. Some very modest individual initiatives have taken place within the military services, the most advanced of which is the publication, in draft form by the Army, of an open source primer for military intelligence officers. At this time the U.S. military does not have timely broad access to a full range of open sources.[5]

-- The Netherlands. Various open sources, including the *Intelligence Newsletter* out of Paris, and *OSS NOTICES* in the United States, have reported that the foreign and military intelligence agencies have been integrated. Within the new national intelligence agency. a special Open Source Coordinator has been appointed, and a task force approach is being taken to intelligence collection and analysis. Every task force has an open source intelligence specialist. and all requirements for intelligence must first be examined and if possible satisfied through OSCINT before tasking of clandestine or technical capabilities is permitted. More recently, the intelligence elements of the individual military services were integrated into a joint military organization reporting to the Prime Minister.

-- Sweden. This country is most interesting because is has a unique consortium within which to formally orchestrate the activities of government intelligence, the business intelligence community, and the university research community. Swedish scientific & technical attaches have been noted to regularly exploit the Internet, and there is discussion within Lund University of the need for an Open Source Intelligence Center™ to meet the combined needs of the government, business, and university communities in Sweden.

Advantages and Disadvantages of Open Source Intelligence

-- Advantages include the fact that OSCINT has virtually unlimited potential on any topic; is of relatively low cost because expertise is maintained at someone else's expense; is generally up to date; and can be shared with anyone.

---

[5] The extraordinary relevance of Department of Energy OSCINT capabilities in support of military operations are described in *SHARING THE SECRETS: Open Source Intelligence and the War on Drugs* (OSS Inc. Limited Edition, 1994). The Army paper, prepared by the 434th Military Intelligence Detachment, Strategic, is titled *Open Source Intelligence Resources for the Military Intelligence Officer* (Fort Huachuca, November 1994).

-- Disadvantages include the possibility of revealing military plans and intentions (security can be provided by laundering the question through trusted intermediaries); the time and cost associated with searching for exactly the right information within the hugh volumes of public information; and the temptation to accept an open source at face value when it could be disinformation or simply inaccurate.

Obstacles to Military Exploitation of Open Sources

There are three obstacles to military exploitation of OSCINT:

-- Organizationally, the military relies on a classified intelligence community for its "intelligence", and does not have an alternate structure established to obtain OSCINT. Among the most important problems created by this reliance are those of funding: there are no well-established programs for contracting directly with the private sector for OSCINT.

-- Culturally, there is a strong attitude, primarily within the intelligence community but to an extent within the operational community, that information achieves a special value only if it is classified. This is in part a result of a cultural inclination to treat knowledge as power, and to withhold knowledge from others as a means of protecting one's power. This attitude is the equivalent of the calvary ignoring the tank and the machine gun. The "openness" paradigm has thoroughly defeated the secrecy paradigm, and those organizations which focus on protecting secrets rather than exploiting publicly available information, will find themselves "starving" for knowledge.

-- Technically, because of the historical focus on training, equipping, and organizing forces for unilateral and conventional military operations, with the added assumption that all "intelligence" will come through classified and well-established channels, the existing command & control architecture, including communications, computing, and intelligence elements, is not designed to rapidly interface with joint and coalition forces, with special forces and direct action clandestine teams, and with the vast array of private sector and non-military government elements which can provide OSCINT to the commander.

Opportunities for Advantage

The Director of Military Intelligence (DMI) for any nation has essentially three opportunities to improve national capabilities to collect, process, and disseminate OSCINT to commanders and military policy-makers:

-- Existing library resources are poorly-funded and organized for the purpose of "just in time" archiving of information. Library resources, both within the intelligence community

and outside the intelligence community, must be recognized as the "source of first resort"[6] Commanders and policy-makers must restore funding for library operations, including the cost of subscribing to external online services and out-sourced research, while at the same time redirect the libraries toward "just in time" decision-support to specific consumers, and away from "just in case" generic collection and processing.

-- Existing military intelligence analysts must be given the training, fiscal authority, and commander's guidance necessary to convert them from narrow specialists focusing on the analysis of classified information, to managers of networks of overt human experts and related electronic and hard-copy databases. At the same time, analysts must be re-oriented so that their primary focus is on day to day interaction with the commander and other consumers of military intelligence, and on day to day collection management founded upon open source exploitation, rather than the existing focus on producing classified reports in isolation from the consumer.

-- Existing commanders, in consultation with the DMI, must recognize that it is impossible for the DMI to satisfy their intelligence requirements related to a wide range of new priorities, with existing classified military intelligence capabilities. The entire structure of military intelligence must be recast to permit rapid maneuver throughout the private sector's knowledge terrain, and the rapid collection, processing, and dissemination of mission-critical OSCINT to the commander at every level of operations (strategic, operational, tactical, and technical) and in "every clime and place".

Role of the Military Reserve

The military reserve constitute a national resource which has enormous potential. A simple example will serve to make the point. For every country of interest, a cadre of five military intelligence reservists could be formed, and given a responsibility to monitor pertinent foreign language periodicals and publications (which would be provided them on subscription), and to prepare weekly OSCINT summaries. These same individuals should be afforded direct access to the Internet and commercial online databases, and serve as direct reinforcements on demand to the active duty military intelligence analysts responsible for the same areas of interest. Funds should also be provided for the five person cadre to spend thirty days each in the country of interest, unencumbered by administrative duties. In this way, when a contingency requirement emerges, the responsible commander can activate the appropriate cadre (or cadres in the case of a theater commander).

---

[6] This important phrase was developed by Mr. Paul Wallner, the first (and last) Open Source Coordinator in the Office of the Director of Central Intelligence in the United States. Mr. Wallner, a member of the Senior Executive Service (flag rank) served for many years in the Defense Intelligence Agency and has been a strong advocate for improving OSCINT support to the commander. Today he serves as Deputy to the first Director of Community Open Source Program Office, Dr. Joseph Markowitz.

APPENDIX B-1

PRIVATE ENTERPRISE INTELLIGENCE: ITS POTENTIAL CONTRIBUTION TO NATIONAL SECURITY[7]

Talking Points

Concepts

Threat: No longer mono-lithic, mono-culture.

Four warrior classes--high-tech brute, low-tech brute, low-tech seer, high-tech seer. Community was built to deal with high-tech brute, is not ready for the other three.

Must distinguish between data (raw print, image, signal), information (collated data of generic interest, including 95% of the intelligence community's production), and intelligence, which is information tailored to support a specific decision by a specific person at a specific time.

Context

Joe Nye's jigsaw puzzle analogy--OSCINT provides context and orientation, and larger share of the puzzle than before.

Information continuum (K-12, universities, libraries, business, private investigators and information brokers, media, government, defense, intelligence) is robust and ready to provide low cost responsive intelligence on many topics today.

Virtual intelligence community in U.S. is a $500 billion per year industry, and *someone else pays the overhead.*

OSCINT is a means of achieving savings which permit reinvestment in improved clandestine and technical collection. *Don't send a spy where a schoolboy can go!*

---

[7] These talking points were prepared by Mr. Robert D. Steele, President of OPEN SOURCE SOLUTIONS, Inc., for presentation to a Canadian intelligence conference, "Intelligence Analysis and Assessment: The Producer/Policy-Maker Relationship in a Changing World, 27-29 October 1994, Ottawa, Canada.

Challenge

Integrated analysis--integrating geographic and civil factors and striving for strategic and operational generalizations and forecasting, not just tactical and technical specifics about military capabilities--requires an order of magnitude increase in the exploitation of open sources.

90% of what the policy maker reads and listens to is not only unclassified, it is unanalyzed. Open sources reaching the consumer reflect a wide variety of competing influences and perspectives--the community is not helping the policy maker make sense of the babble.

"Just in time" intelligence support means just in time collection as well as production. Linear paradigm (consumer to analyst to collector to source, and back up) is dead. New paradigm is the diamond paradigm, where all four talk to each other at one time or another.

Must resolve the dilemma of whether intelligence is about secrets, or about informing policy. 80% of what is needed to inform policy is unclassified, and unclassified intelligence is much more useful politically.

Change

We used to promote analysts for mastering classified data in isolation from open sources, collectors, and consumers. This will no longer be the case.

The analyst of tomorrow will be a manager of a network of overt human sources who serve as distributed filters of unclassified information, and provide "on demand" guidance as to the most pertinent sources and data.

The analyst of tomorrow will be a partial extrovert skilled at "recruiting" the consumer and maintaining direct personal relations with the consumer.

The analyst of tomorrow will be both a resource manager and a collection manager, able to draw from open sources to the fullest extend possible, while tasking clandestine and technical sources as needed.

Country

The intelligence community cannot reinvent itself in isolation. To harness the distributed intelligence of the Nation and optimize its exploitation of open sources, the intelligence community--the Nation--requires a national information strategy.

That strategy should enable connectivity across the information continuum; nurturing and exploitation of distributed centers of excellence focused on content; coordination of information technology research & development; and establishment of Nation-wide standards of communications & computing security.

In the information age, only smart nations will prosper and survive. The intelligence community is a vital but not a sole source of national intelligence. The smart nation must integrated classified government capabilities with unclassified private sector capabilities to create a new form of national intelligence.

PRIVATE ENTERPRISE INTELLIGENCE: ITS POTENTIAL CONTRIBUTION TO NATIONAL SECURITY

Robert David Steele[e]

95% de l'information dont une entreprise a besoin peut s'acquirir par des moyens honorables.

Henry Stiller, Director General
Histen Riller, Societe Civile

ABSTRACT: In an era when both the nature of the threat and the definition of national security have undergone radical redefinition, it is essential that the intelligence and security services understand what their consumers have recognized for many years: private enterprise intelligence capabilities are robust, diverse, responsive, and relatively inexpensive. As we all strive to "reinvent" our intelligence and security services, the potential contribution of the private sector must be understood and integrated into our final design. At the strategic level, the private sector provides the context for classified and technical collection; at the operational level, the private sector is well ahead of the government in pursuing new concepts for intelligence dominance; and at the tactical level, the private sector now offers open sources and services which can meet roughly 80% of the needs of traditional and emerging intelligence consumers.

Losing Our Way

Too often we in the intelligence community forget our roots and abandon our private sector allies. Spies existed before Christ, but most of them were actually legal travelers and

---

[e] *Mr. Steele is President of OPEN SOURCE SOLUTIONS, Inc., a non-profit educational association established to assist governments and private sector organizations in understanding and capitalizing upon private enterprise intelligence capabilities, generally known as "open source intelligence" (OSCINT). In 1992 he was named one of the "Microtimes 100: industry leaders and unsung heros who made a difference in the computer industry in 1992 and helped create the future". In 1993 he was featured by Alvin and Heidi Toffler as "The Rival Store" in their chapter on "The Future of the Spy", in War and Anti-War: Survival at the Dawn of the 21st Century. Mr. Steele is a veteran of the clandestine service of the United States of America, has helped manage overhead satellite programs, and was the founding Deputy Director of the Marine Corps Intelligence Center, where he developed many of his findings on the relative utility of OSCINT as a substitute or complement to the traditional intelligence collection disciplines.*

discreet merchants. Tea was stolen from China, and porcelain from England, by merchants.[9] More recently Japan, China, and Taipei have demonstrated profitable and cost-effective private intelligence capabilities. France and Israel excel at government support to the private sector, but I speculate that soon it will be the private sector that is conducting most of the espionage as well as the open source intelligence (OSCINT) collection in these two countries.[10]

The Anglo-Saxon intelligence communities lost their way in the late 1950's, largely because of over-reliance on the American intelligence budget as a safety net, with the unfortunate result that the American tendencies to ignore counter-intelligence and cultural intelligence, and to rely on technical panaceas and bean counting, infected the other services and skewed the manner in which our respective intelligence services trained, equipped, and organized for sustained warfare against "the threat".

Among the worst of the American influences on Anglo-Saxon intelligence were its obsessive focus on the Soviet Union as the only enemy worthy of total attention; and the

---

[9] The "privatization of intelligence" is a concept—indeed a sub-discipline--which owes a great deal to Dr. Stefan Dedijer of Lund University in Sweden. His contributions were honored with a book dedicated to him, by Jon Sigurdson and Yael Tagerud, *The Intelligent Corporation: The Privatization of Intelligence* (Taylor Graham, 1992). Most recently, aided by one of his more promising disciples, Ms. Katarina Svensson, Ph.L., he published *Technical Attaches and Sweden's Innovation Intelligence* (Lund University, April 1994). It is not my task here to provide citations to the literature critical of classical intelligence, but I do wish to acknowledge the lasting influence of Mr. Loch K. Johnson, whose article "Seven Sins of Strategic Intelligence", *World Affairs* Volume 146 Number 2 (Fall 1983), and subsequent book, *A Season of Inquiry: The Senate Intelligence Investigation* (The University Press of Kentucky, 1985), set the stage for the critical exploration of alternative sources & methods. In the final note I provide several references focused strictly on private enterprise sources and methods.

[10] I consider the Swedes to be the "stealth Japanese" of the Anglo-Saxon intelligence world, and also--with the Dutch--to have the most potential for creating the first Anglo-Saxon "intelligent Nation". Outside the Anglo-Saxon world I look to India, Viet-Nam, and Saudi Arabia to set new standards of excellence in government and private sector intelligence endeavors, and in fact speculate that they have already enjoyed significant successes. The dark side of private enterprise intelligence is represented by the criminal gangs--where the Colombians have been relatively unsophisticated, but omni-present in shadowing every U.S. frigate and aerial observation aircraft, I see the Russian, Vietnamese, Korean, and Japanese criminal organizations as cohesive, well-funded, and highly sophisticated. They represent a major threat which law enforcement will not be able to handle without a radical redefinition of both the responsibilities of national intelligence, and the support obligations of national defense.

American "solution" for poorly managed human intelligence (HUMINT) against the Soviets[11], an extremely expensive and deceptively ineffective technical collection empire which had the unanticipated impact of precluding American HUMINT from developing into a serious clandestine service. A side effect of the American resort to extremely expensive and highly classified[12] imagery intelligence (IMINT) and signals intelligence (SIGINT) overhead collection systems was the abandonment of the robust, diverse, responsive, and relatively inexpensive capabilities of the private sector.[13]

---

[11] In the aftermath of World War II, the Americans displayed their distressingly usual tendency to take the easy way, and attempted to penetrate the Soviet Union using emigres and others from organizations which had already been thoroughly penetrated by Soviet intelligence. When all of these "agents" were captured and executed, rather than doing some serious soul-searching and then creating a more serious illegals capability, the Americans turned to the U-2 and its follow-on satellites as an "acceptable" alternative to traditional spycraft. Now we find ourselves facing a wide range of threats which are not amenable to technical penetration, while we are simultaneously handicapped by the absence of a clandestine service worthy of the name.

[12] Americans (among others) have developed the art of secrecy as a means of concealing ineffectiveness, inefficiency, and irrelevance. Although the technical disciplines, both imagery and signals, have much to offer our communities, the reality is that we process less than 10% of what we collect, and we disseminate roughly 10% of what we process (*ergo* we disseminate 1% of what we collect), and it is highly questionable as to whether the technical disciplines provide the return on investment that they should in comparison with either clandestine intelligence or open source intelligence. My detailed comments on the costs of secrecy is contained in my invited *Testimony and Comments on Executive Order 12356, "National Security Information"*, to the Presidential Inter-Agency Task Force on National Security Information, Department of Justice, 9 June 1994. For a related comment, consider the statement of Rodley B. McDaniel, then Executive Secretary of the U.S. National Security Council and a former Senior Director (White House) of the Crisis Management Center. Speaking to a senior executive service class at Harvard University, he stated: "Everybody who's a real practitioner, and I'm sure you're not all naive in this regard, realizes that there are two uses to which classification is put: the legitimate desire to protect secrets, and protection of bureaucratic turf. As a practitioner of the real world, it's about 90 bureaucratic turf; 10 legitimate protection of secrets as far as I'm concerned." As reported in Thomas P. Croakley (ed.), *C³I: Issues of Command and Control* (National Defense University, 1991), page 68.

[13] It was an enormous shock to me, while serving as the senior civilian responsible for the establishment of a new $20 million intelligence production center, the Marine Corps Intelligence Center, to discover that the $2 million per year we earmarked for a Top Secret Sensitive Compartmented Information (TS/SCI) computer system with direct access to data from the Central Intelligence Agency (CIA), National Security Agency (NSA), and Defense Intelligence Agency (DIA) proved to be virtually worthless. The analysts kept coming in

It is instructive. in thinking back to the early days of the Office of Strategic Services (OSS), to consider how very important the academics from the private sector were to the development of our analysis methods, and how very important open sources were to our strategic intelligence efforts. The anecdote about the price of oranges in Paris as an indicator of the effectiveness of our bombing attacks on the railroad bridges leading to Paris is a classic. In a more humorous and yet deadly serious vein, consider the story told by Miles Copeland, about how the OSS handled the innumerable requests from the Department of State and the Pentagon which did not merit clandestine collection.

The OSS put two men in a room with *The New York Times*. Anything that could be answered from this open source was typed up, stamped secret, and disseminated as the result of a highly compartmented human intelligence operation--and one which was ostensibly very expensive, hence justifying requests for additional funds. The information itself was not fabricated, only the purported methods of acquiring it.[14]

---

saying "there's nothing there but Soviet missile silo data, the Third World 'data fill' has not been done". I subsequently discovered that I could meet 80% of the intelligence requirements of the Marine Corps through the use of open sources, as a cost of roughly $20,000 a year expended in subscriptions to LEXIS/NEXIS, EasyNet, Jane's Information Group. and several other private enterprise information services. Our first major product. for which I served as Study Director, was an unclassified review of 69 countries of interest to the Marine Corps. Titled *Overview of Planning and Programming Factors for Expeditionary Operations in the Third World* (Marine Corps Combat Development Command, March 1990). this product was unique for relying strictly on unclassified sources, and was embraced by the operational community because it a) asked them to define beforehand what they considered to be the key factors as well as the distinctions between high. medium, and low degrees of difficulty for each factor; and b) it could be easily shared with pilots and platoon commanders as well as coalition partners and the press. It was this experience that led to the subsequent Congressional interest and my launching of a public campaign--while still a government employee and with the approval of my General Officer--to radically realign resources between open and traditional sources of intelligence.

[14] Miles Copeland, *Without Cloak or Dagger: The Truth About the New Espionage* (Simon and Schuster, 1974), pp. 47-48. It was with great amusement that I listened to four recently retired KGB officers, speaking at OSS '93 on the topic of "Soviet Exploitation of U.S. Open Sources During the Cold War". To a packed room, they described how often "Centre" would catch them in the act of using open sources as a substitute for successful agent operations, and how open sources were in fact a mainstay of their Cold War scientific & technical collection efforts. Second International Symposium on "National Security & National Competitiveness: Open Source Solutions", Washington, D.C., 2-4 November 1993. The officers speaking were Colonel Vladimir B. Barkovsky. Ph.D. (former Deputy Director, KGB Science & technology Institute); Colonel Yuri I. Modin, Ph. D. (former Deputy Director. Research Institute on Intelligence Problems): Colonel Vsevelod I. Gapon (former

OSCINT has maintained a modest role within the larger intelligence communities, and a more central role within the smaller intelligence communities, but the reality is that the Anglo-Saxon intelligence communities of today exploit less than 10% of what is available from the private sector.

It is our task to explore the larger strategic context within which private enterprise intelligence can make a contribution to national security; to understand operational concepts from private enterprise intelligence which can and should be adopted by the traditional government intelligence services; and finally, to inventory, at this point in time, some of the specific private enterprise intelligence capabilities which can be used by the government to achieve both tactical results and sustained savings.

OSCINT and the Changing Threat

Others participating in this conference have addressed the changing threat and changing intelligence agenda, but I wish to outline here an intellectual construct which influenced my early appreciation of how poorly our intelligence community exploits private sector intelligence capabilities, and how relevant OSCINT is to the threats that have always been with us, but which are receiving a more appropriate degree of interest today.

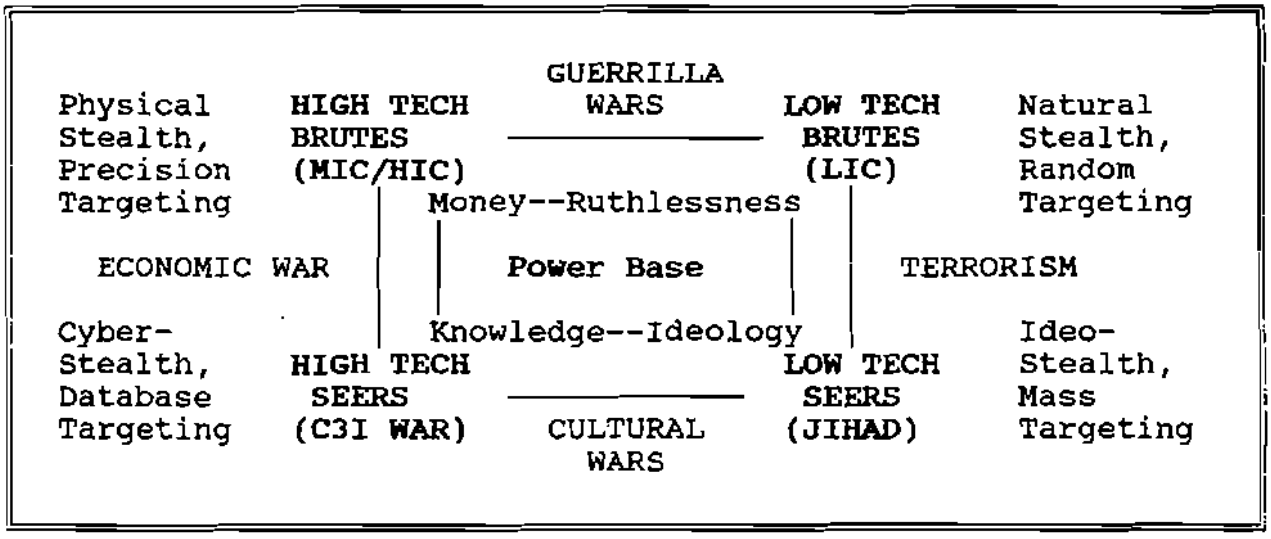

Figure 1: The Four Warrior Classes and Implied Intelligence Challenges[15]

Deputy Chief of Division, KGB); and Colonel Yuri H. Totrov (former KGB Section Chief for Counterintelligence, Central Intelligence Agency Affairs).

[15] This graphic is from my article "The Transformation of War and the Future of the Corps" in *INTELLIGENCE: Selected Readings--Book One* (Marine Corps Command & Staff College, AY 1992-1993). It is my privilege to continue serving the Marine Corps as Adjunct

While there are obviously variations to these four categories (for instance, some international criminals now use very sophisticated Swiss encryption and communications devices, as well as computer Van Eck emissions capture devices), these four categories helped me focus on the original threat--the high tech brute or conventional military opponent --while also keeping sight of the three major emerging threat categories.

What I perceive in this matrix is two fundamental aspects of national security and national intelligence:

a) First, since the National Security Act of 1947 which created the U.S. intelligence community, all that has followed has led to an intelligence community trained, equipped, and organized to deal with a single monolithic "high-tech brute", the Soviet Union, and very poorly trained, equipped, and organized to deal with smaller high-tech brutes, such as Iraq, or the other three major categories of threat. In particular, national intelligence capabilities in support of both international and domestic law enforcement, and economic competitiveness, are mediocre to non-existent.[16] We do not have the long-term ethnic human penetrations we need against international criminal organizations, nor do we have the kind of tactical SIGINT capabilities, or even air-breathing tactical IMINT, that would be helpful in coping with this robust international cancer.[17] We find that cultural movements baffler our

---

Faculty for Intelligence. My thinking was stimulated by Martin Van Crevald during his tenure as a Visiting Professor at Command & Staff College, and by his book *The Transformation of War* (Free Press, 1991).

[16] For a detailed critique of the existing U.S. intelligence community, a critique which draws on my years of service both in the Central Intelligence Agency as well as the Marine Corps, including participation in all of the post-mortems on intelligence failures in the Gulf War as well as Marine Corps support to the Department of Defense "reinvention of intelligence" initiatives undertaken by then Assistant Secretary of Defense for Command and Control, Communications, Computing, and Intelligence, Mr. Dwayne Andrews, see "A Critical Evaluation of U.S. National Intelligence Capabilities" in the *International Journal of Intelligence and Counterintelligence* (Volume 6, Number 2, Summer 1993). More recently I have summed up four years of critical commentary in "Reinventing Intelligence: Holy Grail or Mission Impossible?", in the *International Journal of Intelligence and Counterintelligence* (Volume 7, Number 2, Summer 1994).

[17] Until recently, very few traditional intelligence analysts were aware of the existence of the International Association of Law Enforcement Analysts (IALEA). This organization represents a first step in transferring some of the methods of analysis developed by the traditional intelligence community into the law enforcement arena. They can be reached at Post Office Box 52-2924, Miami, Florida, 33152, Voice: (305) 653-3010, Facsimile: (305) 716-3218. When I participated in reviews of intelligence effectiveness against low intensity conflict targets, one of the most critical deficiencies was the fact that our systems could not deal with "low slow singleton" targets. A major deficiency within the military is its

indications & warning (I&W) system because they do not use point to point communications but rely instead on couriers, the pulpit, and broadcast television to indirectly mobilize action elements from within the masses.[18] We do not have an electronic counter-intelligence capability worthy of the name, nor have we established the most basic economic counter-intelligence capabilities.[19]

b) Second, and this stems from a personal awaking inspired by the failure of our Marine Corps Intelligence Center's $10 million classified intelligence computing system and related classified databases, when contrasted with a $20,000 a year expenditure on private enterprise information sources and services, it is clear to me that OSCINT can meet 80% of our needs for intelligence against the emerging threats, and that OSCINT must be the foundation upon which we completely restructure our classified capabilities.

Now, there is going to be a natural tendency on the part of the "old boys" to say that OSCINT is all well and good, but not for critical national security issues. I have heard this from the best of them, including flag officers in England and France. I have also heard from flag officers in the U.S. and England, and officers in other countries, that they are fed up with classified intelligence that is relatively useless to their day to day needs, and highly interested in streamlining and improving their direct access to private enterprise information

---

propensity to procure "fast movers" (jets) with very limited loiter times over the target area, at the same time that they decline to invest in the necessary "sensor to shooter" collection and connectivity so that these expensive toys can be effective against low slow singletons targets.

[18] One of the finer pieces of journalism I have encountered was a superb series, each article taking up an unheard of full newsprint page or more, in *The Washington Post*. On Monday 2 August 1993 they published "Islamic Warriors: Radical Movements Thrive on Loose Structure, Strict Ideology", and a sidebar article, "Militarized Hezbollah Follows Lead on Iran". On Tuesday 3 August 1993 they published "Islamic Warriors: Global Network Provides Money, Haven", with a sidebar article on "A New Strain of Terrorism: Groups are Fast, Loose, Hard to Find".

[19] Many of my thoughts on information warfare, and information peacekeeping, are contained in my lecture "War and Peace in the Age of Information", presented by invitation to the Naval Postgraduate School at Montery, California, as a Superintendent's Guest Lecture on 17 August 1994. Among other controversial elements, this lecture outlines how I would completely neutralize U.S. military and civil capabilities through electronic attacks on ten specific targets. More recently my friend Winn Schwartau has published a superb book, *INFORMATION WARFARE: Chaos on the Electronic Superhighway* (Thunder's Mouth Press, 1994), a detailed review of the specific capabilities and threats associated with personal, corporate, and global information warfare.

sources.[20]

Let me offer just two short proofs. In 1991 over 100 senior officers, including ten Colonels from the Marine Corps (an unheard of investment for a single event from this

---

[20] For a current critique of the U.S. intelligence community by a prominent consumer, see former Secretary of State George P. Shultz's *Turmoil and Triumph: My Years as Secretary of State* (Charles Scribner's Sons, 1993), pp. 50, 297, 307, 312, 425, 492, 493, 595, 619 *passim.* One Marine Corps general officer has stated that he used to talk about intelligence being broken, until he realized that this implied it existed--in his view, national intelligence simply does not "exist" when it comes to supporting expeditionary military operations. I am fully familiar with the open source intelligence capabilities of the U.S. intelligence community, and in fact served as the Marine Corps member of the Open Source Intelligence Council until my resignation from the Corps on 1 April 1993. The Foreign Broadcast Information Service (FBIS) and the excellent scientific & technical intelligence capabilities developed by the National Air Intelligence Center (NAIC), the National Maritime Intelligence Center (NMIC), and the National Ground Intelligence Center (NGIC) all merit respect. Unfortunately, the U.S. intelligence community spends less than 1% of its budget on open sources (while admitting that open sources provide 40% of the all-source product), and is in my judgement tapping less than 10% of the private sector's capabilities. Among the obstacles to improved OSCINT are an archaic security system, a culture that thrives on secrecy rather than results, and a procurement system that makes it very easy to spend millions on hardware, while making it virtually impossible to subscribe to LEXIS/NEXIS or pay a consultant a quick $1,000. I am totally committed to protecting and improving the U.S. national intelligence community, and attempting to preserve its present level of funding, but in the absence of radical realignments among the disciplines and between collection versus distributed analysis, the community is in for some rough years. The first community attempt at defining its open source intelligence strategy was so disappointing, without reference to past studies or known experts, that I was obliged, as a Marine Corps civilian, to produce *United States Marine Corps Comments on Joint Open Source Task Force Report and Recommendations: Working Group Draft Dated 6 January 1992* (Headquarters, U.S. Marine Corps, 11 January 1994). The intelligence community finally appointed an Open Source Coordinator, Mr. Paul Wallner, to whom I am indebted for his integrity in supporting our private sector advocacy of open source intelligence developments; more recently Dr. Joseph Markowitz has been appointed Director of the Community Open Source Program Office (COSPO), with Mr. Wallner as the Deputy for this much-expanded effort. I have a very high regard for both of these gentlemen--but they are not being given the inter-agency authority and resource control they require to truly make OSCINT "the source of first resort", as Mr. Wallner has correctly defined it. I do not believe the U.S. intelligence community will truly restructure until it faces the real threat of a 50% (fifty percent) cut in its budget over five years, a threat which may well materialize in 1994 as an outcome of the newly established Warner Commission (formally known as the Commission on the Roles and Capabilities of the United States Intelligence Community).

austere Corps). met at the Naval War College in Newport for Technology Initiatives Game 1991. This game was a first effort to scrub Admiral Jerry Tuttle's COPERNICUS program. and included an Intelligence Cell. Here is a paraphrase of what the Navy Wing Commander (Captain, O-6) who led the lead flight into Baghdad said:

> *If it is 85% accurate, on time, and I can share it, that is a lot more useful to me than a compendium of Top Secret/Codeword information that is too much, too late, and needs a safe and three security officers to move it around the battlefield.*[21]

We in the intelligence community must be mindful of the acceleration of the operational tempo, and the fact that our consumers are not stupid. They are growing impatient with the ability of the intelligence community to "keep up". In the Gulf War the classified imagery cycle took eight days from articulation of the requirement to deliver of the imagery. The operational planning cycle was three to five days. Classified imagery was not only poorly suited for wide area surveillance, but it was always too late to be really useful. By contrast, you now have real-time imagery delivery from SPOT, and commercial synoptic one-meter imagery is a year or two away from reality. CNN is blanketing the battlefield, and although it is often wrong, it influences policy and operations. Commercial online services and international executive investigative services are offering astute consumers a degree of tailored intelligence support which is not available from the intelligence community for anyone other than the President or Prime Minister.

More recently, we have the instructive example of OSCINT in the war on drugs. Without belaboring the point, as an entire book will be coming out shortly on this topic, Los Alamos National Laboratory has demonstrated that for $100,000, using only OSCINT, it can do better at estimating global drug production and movement than an equivalent effort by the U.S. national intelligence community, at a cost of $12-15 million dollars.[22]

OSCINT and Changing Definitions of National Security

With the globalization of demographic and ideological movements, as well as the globalization of crime and the economy, the intelligence community is finding itself hard-

[21] Marine Corps Trip Report, Technology Initiatives Wargame 1991, Naval War College, 21-25 October 1991, disseminated by Assistant Chief of Staff, Command and Control, Communications and Computer, Intelligence and Interoperabillity, Ltr C4I2R dtd 3 January 1992.

[22] Dr. James Holden-Rhodes, *SHARING THE SECRETS: Open Source Intelligence and the War on Drugs* (forthcoming), extract from Chapter 5. This book has been selected for distribution at OSS '94, and 1,000 copies will be especially printed by OSS, Inc. one year in advance of the book's release to the public by the prospective publisher.

pressed to meet the needs of its consumers for intelligence about areas which have traditionally been excluded from its charter, such as strategic economic intelligence assessments which must of necessity draw on comparative domestic economic information: or support to law enforcement in its increasingly dangerous efforts to contain very powerful and very ruthless international criminal organizations with solid ethnic cohesion.[23]

It was instructive to me, in January 1994, to hear Ms. Ellen Seidman, Special Assistant to the President of the United States, discuss her responsibilities on the National Economic Council, and her perceptions of both intelligence and normal governmental information processes. In brief, she found the intelligence community irrelevant to her mandate because in the U.S. the intelligence community is not permitted to develop strategic assessments about domestic matters, even economic competitiveness matters. At the same time, Ms. Seidman expressed frustration with the normal governmental information processes, such as represented by the Federal Reserve Board and the Departments of Commerce, Treasury, and Labor, because the latter do not have any concept of how to collect. process, and disseminate intelligence. They don't "do" collection management. or critical analysis, or forecasting. or indications & warning. at the level of sophistication which our intelligence communities have developed over time.[24]

As we reinvent intelligence, there is clearly a need to reconsider not only our sources and methods, but the range of inquiry and the broadness of the consumer base. In my judgement the intelligence community must find a new balance between supporting more consumers with non-traditional requirements including domestic information requirements, while also relying on open sources and private enterprises to fulfill most of the encyclopedic intelligence requirements. The intelligence community. cannot, however, centralize its management of OSCINT, nor can it even presume to control what reaches the consumer. There is a strategic approach which must be taken to integrate government intelligence with private enterprise intelligence.

---

[23] Mr. John Petersen, President of the Arlington Institute (and former staff member of the National Security Council) defines national security in this way: "The Nation's security is no more than the total of the individuals' perceived sense of security (at home and abroad)." He uses a matrix from "Here to There" and "Peace to War" to show the broadening of national security concerns to include "Here" and "Peace" as major areas where both our defense community, and our intelligence community, are not prepared. Personal communications.

[24] Ms. Seidman was speaking to the Open Source Intelligence Lunch Club in Washington, D.C. on 11 January 1994. Her remarks were reported in ***OSS NOTICES*** Issue 94-001 dated 21 February 1994, page 10.

OSCINT and the Consumer

As we consider how best to integrate OSCINT capabilities from the private sector with both old and new classified intelligence capabilities, we must remain acutely conscious of the realities which characterize our consumer's acceptance and exploitation of information.

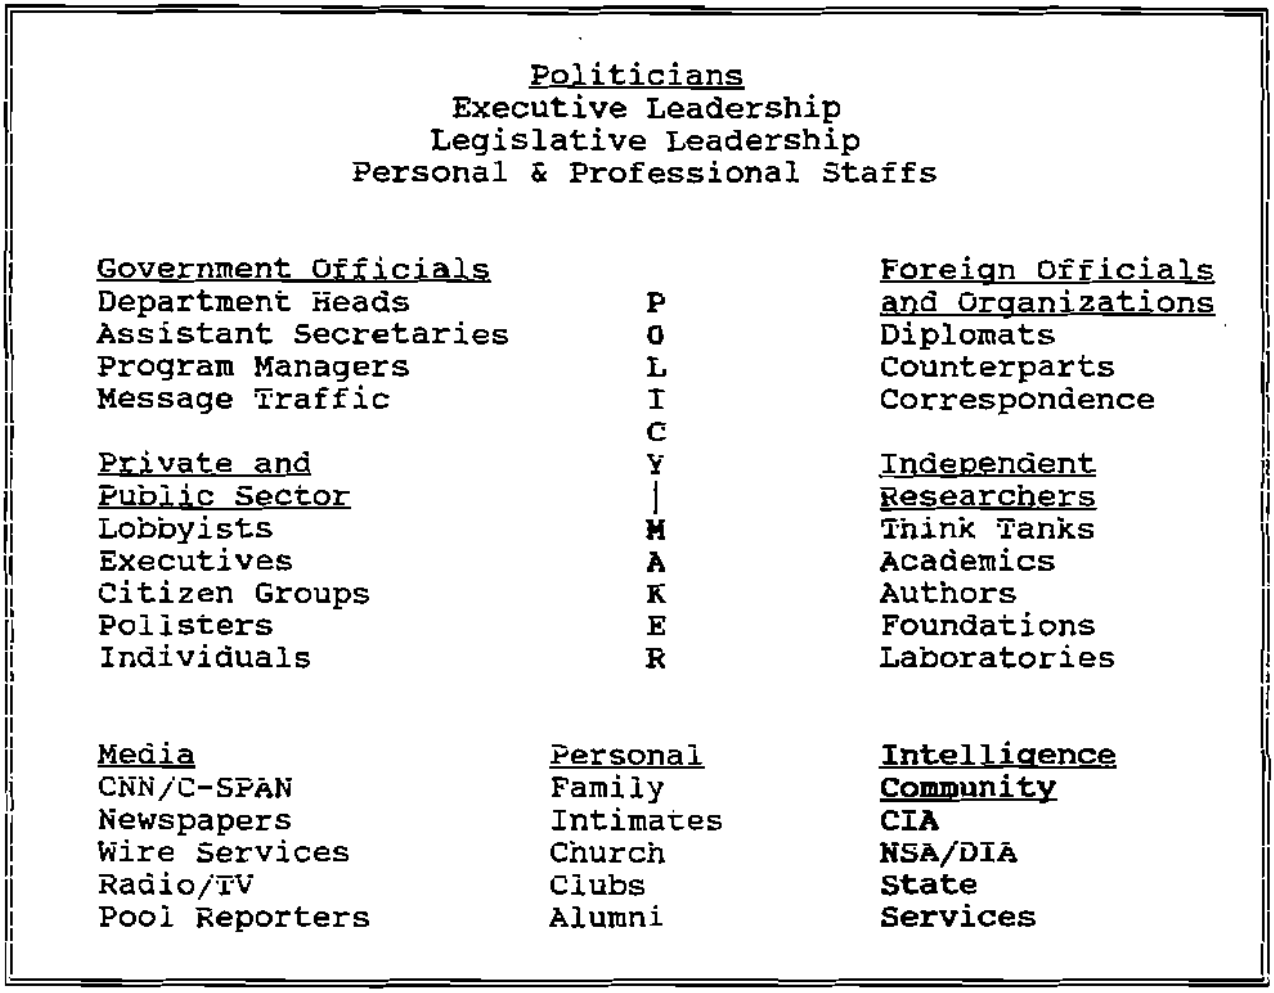

Figure 2. Competing Influences on the Policy-Maker

Consider the above figure, a graphic depiction of the range of "open sources" reaching the consumer each day, independent of the intelligence community:[25]

---

[25] This chart is reproduced from "A Critical Evaluation....", *supra* note 8, and in turn taken from the CIA "Intelligence Successes & Failures Course" which I understand has been discontinued. Dr. Jack Davis, Senior Intelligence Service, was for many years the keeper of the flame for "real world analysis", and the only senior officer willing to stand up to those who would politicize intelligence analysis and pretend that going through the motions constituted real intelligence. Others whose integrity and vision merit recognition including

a) Ninety percent of what the consumer reads and listens to is not only unclassified, but also unanalyzed and unrelated to the classified information sent to them.

b) There is no penalty to the consumer for ignoring classified information.

c) Classified information often comes with so much security baggage as to be an untenable contender for the policy-level consumer's attention (and the executive assistants do not have the codeword clearances, so even the consumer's filtering mechanism is of no help in flagging "useful" codeword material).

d) Unclassified material, even if inaccurate, if it fits the consumer's worldview or agenda, is immediately useful as something which can be disseminated to the press, the public, or Parliamentary personalities.

One of the most important changes the intelligence community can make, one which both addresses the potential as well as the hazards of unbridled open sources reaching the consumer directly, is to develop a much more extensive network of analyst-operators assigned to specific consumers and attending directly to their daily needs. Only through day to day interaction, and physical co-location, will such intelligence community representatives be able to a) monitor the OSCINT reaching the consumer, b) earn the consumer's trust and confidence; and c) properly channel requirements for timely action by the classified world, and d) "pull" exactly the right intelligence from the classified world in such a way as to be directly pertinent to the consumer's needs of the moment.[26]

---

the instructors for the Harvard "Intelligence Policy Seminar", notably Drs. Ernest May and Richard Neustadt, and in recent years, including the course I attended, Dr. Gregory Treverton (now Vice Chairman, National Intelligence Council). Mr. Doug MacEachin, the current Deputy Director for Intelligence (DDI) is a superb officer laboring under enormous constraints to improve intelligence analysis--as he has commented to a meeting of the Security Affairs Support Association, in paraphrase, "it is hard to do serious analysis when you have a bunch of 19-year olds on two year rotations". The entire concept of what constitutes the "value-added" role of national intelligence needs redefinition.

[26] The best article I have seen on how best to do intelligence analysis within the kind of competitive environment provided by OSCINT from private enterprises is that of Mr. Andrew Shepard, a senior analyst now on detail to the Community Management Staff (CMS). His "Intelligence Analysis in the Year 2002: A Concept of Operations", was published in the *Proceedings* (Volume I) of the First International Symposium on "National Security & National Competitiveness: Open Source Solutions" (McLean, Virginia, 1-3 December 1992), and is beginning to have an impact outside the United States. The paper was first presented at the Symposium on Advanced Information Processing and Analysis (Reston, Virginia, 24-26 March 1992). Mr. Shepard capably articulates how on-site intelligence analysts can fulfill three major roles in direct support of the consumer: real time validation and review of

The Strategic Context of Private Enterprise Intelligence

When we lost our way in the late 1950's, and fell in love with technology and the simplicity of a world with only one "main enemy", we built ourselves a cement bunker with no windows. In their time, satellites were like an oasis in the desert. However, in the past twenty years private enterprise information collection, processing, and dissemination alternatives have exploded--unfortunately, for those within the bunker, with its bad air and depleting supplies, it is difficult to notice such changes. It is a tribute to the organizers of this conference, and those behind them, that OSCINT is receiving a full and proper hearing in Canada.

The strategic context of private enterprise intelligence is a fundamental starting point for the reinvention of intelligence. There is no more promising aspect of our profession than that offered by the private sector. While we must assuredly pursue improvements in both clandestine and technical collection sources and methods, OSCINT--the private sector--must of necessity serve as both the "stopgap" measure by which we meet requirements for which our community is not trained, equipped, and organized; and also the benchmark against which we evaluate the value of clandestine and technical capabilities applied to new targets.

In the tactical section which concludes this paper I provide examples of specific private enterprise information-intelligence capabilities from each of the above. At this, the strategic level, I wish to make three points:

a) First, the consumer is now in charge, and acutely conscious of the advantages which OSCINT provides, not only in terms of responsive information at a very low cost, but in terms of political advantage....OSCINT can be shared with the press and Parliament, and therefore is much more politically potent than a secret report which cannot be shared.

b) Second, this is the age of distributed information. It is simply no longer possible to centralize control over collection, storage, processing, and dissemination. I have stated publicly my view that the "Central" Intelligence Agency is not long for this world--that is not to say that we do not require its capabilities, simply that the way in which it is now organized and managed is so ineffective and inconsistent with the realities of today, that it must inevitably join the mammoths in the tar pit.[77]

OSCINT reaching the consumer independent of the intelligence community: real-time retrieval from intelligence community databases of that information which can be tailored to support an imminent decision by the consumer; and collection management tailored to the needs of the consumer rather than the circumstances of the collectors.

[77] My most detailed statement on where I see the U.S. intelligence community developing, to include the dissolution of the Central Intelligence Agency (and the establishment of a separate Clandestine Services Agency) is contained in ***OSS NOTICES***

c) Third, it is simply not advisable, for both political and financial reasons, to render classified intelligence support to private enterprise with any consistency, or with an assured return on investment. In coming to this conclusion I draw on my participation in a special workshop within the Harvard Executive Program on Intelligence Policy (1991).[28] There is no question but that classified economic espionage is required to "illuminate the playing field" for the governmental policy maker. However, given the fragmentation of ownership, management, and employment of most international firms, defining a strictly American or strictly Canadian firm meriting the expenditure of taxpayer funds for classified intelligence becomes problematical. What I found most interesting, though, in thinking about this issue with my classmates, was my personal conclusion that the single best thing the government can do for national competitiveness is to nurture the growth of what Lee Felsenstein calls the

---

Volume 2, Issue 6, 30 August 1994). Among the highlights: dissolution of the Central Intelligence Agency; establishment of a separate Clandestine Services Agency (CSA) under total non-official cover; conversion of the Directorate of Intelligence into the cadre for an inter-agency series of intelligence centers under the oversight of the National Intelligence Council; creation of Deputy Directors of Classified Intelligence for Research & Development, and for Communications & Computing; integration of the National Reconnaissance Office (NRO) with the Defense Mapping Agency (DMA) to create a Defense Mapping & Reconnaissance Agency which contracts out 75% of its collection and production; expansion of the National Security Agency (NSA) charter to include monitoring of unencrypted cyber-space data and the establishment of a clandestine capability for inserting alternative transmitters into sites using unbreakable encryption; and expansion of the Defense Intelligence Agency (DIA) to manage a totally integrated Intelligence Corps which provides the military intelligence personnel to all military elements from the forward-most tactical element through the Joint Intelligence Centers (JIC) and into the Pentagon. A superb book on emerging governance principles for distributed networks is that of Kevin Kelly (editor of *WIRED Magazine*), *OUT OF CONTROL: The Rise of Neo-Biological Civilization* (Addison-Wesley, 1994). One of the concepts which Kelly articulates is that of "hive mind". In my own work I am pursuing ideas once articulated by Teilhard de Chardin and Quincy Wright, among others, with respect to what constitutes an "intelligent nation". I envision a "virtual intelligence community" which is 100 times larger and more encompassing than the existing intelligence communities; while such a community must by definition be "out of control", it is in fact far more effective and responsive to the needs of our consumers than the existing government intelligence communities (and their non-intelligence uninformative counterpart agencies).

[28] This course, sponsored by the Central Intelligence Agency, brings together approximately thirty general officers and their senior civilian counterparts, each at a point where they are about to manage the entirety of their organization's intelligence resources. As the second civilian in the very small Marine Corps intelligence pond, I benefitted from this opportunity around eight years earlier than I might have in a larger organization.

"information commons" of open source multi-media data.[29]

Let me expand on this concept for a moment. Our own Deputy Assistant Secretary of Defense for Intelligence and Security, Mr. Keith Hall, has stated clearly that while intelligence must of necessity rely on OSCINT for context, that intelligence is intended to collect secrets not available "by other means", and that OSCINT falls firmly within the category of "other means".[30] What we have here is a dilemma. On the one hand, we want the intelligence community to focus on secrets. On the other hand we have to keep the policy-maker informed, and find that 80% of the time OSCINT is better at informing policy than are secrets. What I believe we need is a new strategic definition of what constitutes "national intelligence"--our definition must provide for a distinction between classified governmental intelligence and unclassified private enterprise intelligence, while also providing for the integration of both under the national intelligence umbrella.

The isolation of the intelligence community from its consumers, and the arrogance of the intelligence community in presuming that it knows best who its consumers should be, and that it knows best whether secrets are better than open sources in any given instance, must be brought to an end.

In essence, it is not enough for the government to simply understand and take advantage of private enterprise intelligence. It is essential that the government have a national information strategy, and that it nurture what I call distributed centers of excellence. It is not enough to expect that the private sector will undertake the necessary collection and processing that is required--government must actively encourage, without controlling, such endeavors, and constantly monitor the state of its national information continuum.[31]

---

[29] Lee works at the Interval Research Corporation in Palo Alto, California, and can be reached at (415) 354-0857, fax (415) 354-0872, email <lee@interval.com>. Interval is Paul Allen's attempt to create a modern Xerox Parc.

[30] Mr. Hall provided his first public address on the relationship between intelligence and open sources to the Open Source Intelligence Lunch Club in Washington, D.C., on 9 August 1994. Mr. Hall, whose rich experience at the tactical level in military intelligence and at the Office of Management and Budget as well as on the Senate Select Committee for Intelligence makes him one of the most qualified senior leaders in our community, was the originator of the term "ASK-INT", and has over the past decade challenged intelligence collectors to determine if the information they want to use expensive methods to collect might not in fact be available for the asking.

[31] In the United States, the National Information Infrastructure (NII) was until recently focused strictly on connectivity. It was with some gratification that I finally heard him speak of the need to harness the "distributed intelligence of the Nation", a phrase I used in my address to OSS '94. He used this phrase when announcing the GII in Brazil, and again at the Public Interest Summit in Washington, D.C. on 29 March 1994.

Below I illustrate what I call the "information continuum". It is very important to note that the intelligence community is but one ninth of that continuum, and that existing security and procurement practices assure the complete isolation of the intelligence community from the other eight sectors. If one regards the intelligence community as the pinnacle of the national information continuum, then the most interesting aspect of reinvention is that associated with new responsibilities for the community--instead of simply collecting information and processing it in a centralized way, the community must now begin the process of nurturing distributed networks which are unwitting or benignly witting, and most assuredly not "under control".

What I call the "information continuum" is the knowledge terrain within which government intelligence and corporate intelligence must operate:

K-12	Libraries	Private Investigators Information Brokers	Government	Intelligence
Universities	Businesses	Media	Defense	

Figure 3: The "Information Continuum" or "Virtual Intelligence Community"

It consists of our elementary and secondary schools, our universities, our libraries, all businesses and their information repositories, private investigators and information brokers, the media including the trade journal and scientific & technical media, governments down to the state and local level, all defense and law enforcement organizations, and the official and usually secret intelligence communities. I call these the nine sectors of the information continuum.

IF we can harness this distributed power, then we can create a "virtual intelligence community" far more capable than the isolated communities now in existence.

The good news is that this continuum provides a low-cost, flexible, and responsive "virtual research department" of extraordinary power and value. The bad news is that very few people know how to navigate this terrain, or how to break down the iron curtains between sectors, the bamboo curtains between industries, the plastic curtains between individuals.

In order to bridge the gap between what we have in the "real" intelligence community today, and what we might have in the "virtual" intelligence community of tomorrow, a national information strategy is an essential pre-requisite. Whether through legislation or through administrative fiat, there must be a concerted effort on the part of the government to harness the "distributed intelligence of the Nation".

In addition to the connectivity that comes with the National Information Infrastructure (NII) and its international extension, the Global Information Infrastructure (GII), three other elements are required to fully harness private enterprise intelligence:

a) There must be, fully independent from the intelligence community[32], a National Information Foundation (NIF), modeled after the National Science Foundation (NSF), which nurtures distributed centers of excellence without attempting to control them or their content.

b) Expenditures for information research and development (both tools and content) must be coordinated to avoid duplicative or counter-productive investments (e.g. every major bank commissioning a separate market survey on Indonesia, or development of a desktop analysts' workstation).

c) Communications & computing security must be assured through national standards, testing & certification laboratories, due diligence legislation, and national education.[33]

In brief then, while the private sector provides a very robust foundation for reinventing intelligence, and private enterprise intelligence can today be exploited well beyond what the intelligence community is doing, only a national program and a national strategy which explicitly recognizes the distributed nature of private enterprise intelligence, and seeks to harness it, will yield the optimal value for national security and national competitiveness.

---

[32] There is no avoiding the fact that most private enterprises, be they commercial or academic, will simply not trust the intelligence community to "manage" or "control" their databases or their activities. The best way to harness the distributed power of the private sector is to create a National Information Foundation (or Institute) which is non-regulatory and distributes funds (rather than centralizes information) to "centers of excellence" chosen because of their focus on specific regions or topics of interest to the government. This would be a non-intrusive means of orchestrating capabilities. OSS, Inc. is in the process of obtaining from every U.S. Senator and Representative their nominations for centers of excellence in their respective States and Districts, as a pre-amble to publishing the first national inventory of centers of national intelligence excellence in the private sector.

[33] Although I have had very good relations with major hacker groups since 1992, when they recognized me for "hacking the intelligence bureaucracy", it was not until this past year that I realized that absolute private security was an essential pre-condition to complete openness. In order to engender the kind of open exchanges that are needed in a distributed intelligence system, it is essential that individuals feel that they a) know who is on the other end with some certainty; b) will receive the original document without modification; and c) can rely on a digital cash payment being transferred if that is part of the exchange. It was this realization that led me to oppose the Clipper Chip, and to testify to the NII Security Committee on 15 July 1994.

Operational Concepts, Policies, and Practices

At the operational level, which deals with top-level guidance of over-all intelligence efforts, rather than the specific research tasks common to the tactical level, I want to highlight some core concepts where I believe that the private sector is ahead of the intelligence community.[34]

Decision-Support is the only acceptable mission for intelligence. One must carefully distinguish between *data*, which is the raw text, image, or signal; *information*, which is collated data of generic interest, such as newspapers or research reports; and *intelligence*, which is information that has been tailored to support a specific decision by a specific person about a specific topic at a specific time and place.[35]

Collecting Secrets is not difficult if you focus on collecting them before they become secrets. The weakest link, and the cheapest and easiest to exploit, is the grey literature and human infrastructure responsible for doing research just before someone decides to label something proprietary or classified.[36]

Cast a Wide Net. The French steel industry worked very hard at competitor intelligence against other steel industries, and completely overlooked the plastics industry.

---

[34] Both the operational concepts and the tactical specifics which follow were developed for my keynote presentation to the Association for Global Strategic Information (AGSI) in Heidelberg on 14 June 1994. That speech, oriented toward strategic planners and senior executives in international business, was printed as "ACCESS: Theory and Practice of Competitor Intelligence", *Journals of AGSI* (July 1994). Both sections have been revised, to include alteration of some of the tactical elements, in order to be more meaningful to a government intelligence community audience.

[35] When I first began developing new concepts for analysis in order to make the very austere Marine Corps Intelligence Center as effective as possible, I undertook a review of all CIA and DIA production available to the Marine Corps from the preceding year. I was intrigued to discover that almost nothing produced by either of these two organization actually supported any specific decision. It was all classified information of generic interest, and of a broadcast nature. I also found that almost all the production focused on a specific topic, weapons system, or country, rather than producing strategic generalizations helpful to long-term assessments and the formulations of strategic plans.

[36] For a detailed articulation of my theory and practice of OSCINT, see "ACCESS: Theory and Practice of Intelligence in the Age of Information". This was prepared for a foreign government which is among the most advanced in exploiting legal and open sources and methods in support of its national competitiveness. The paper was published in Volume I of the *Proceedings* of the Second International Symposium on "National Security & National Competitiveness: Open Source Solutions" (Washington, D.C., 2-4 November 1994).

which was busy developing steel substitutes.[37]

Openness versus Secrecy. The openness paradigm has won. The example of the nuclear industry, based on secrecy and not very progressive, is instructive when compared with the openness of the electronics industry, where competing engineers compare their approaches over coffee.[38]

Just in Time versus Just in Case. Paul Evan Peters, Executive Director of the Coalition for Networked Information, makes the point that in the age of distributed information easily accessible through electronic connectivity, it makes no sense to store volumes of out-of-date information when you can reach out and get exactly what you need in the way of current information on a "just in time" basis.

Leverage Everyone Else's Overhead. An expansion of the above concept is that of avoiding the enormous costs of attempting to maintain, with limited sustainability, in-house experts and in-house archives on everything. The private sector contains many superb information and intelligence capabilities where the resident expertise, and the existing databases, are maintained at someone else's expense. The intelligence community must do a much better job of exploiting such centers of excellence. *The most important contribution these external elements can make is not as a substitute for in-house analysis and the final production of an integrated classified product, but rather as self-sustaining information filters and on-demand experts able to rapidly identify the latest and best multi-media information pertinent to a specific decision area--information that can then be rapidly acquired, evaluated, and integrated.*[39]

---

[37] I heard this marvelous anecdote from Mr. Herve Serieyx, Vice President of the Institute for European Leadership, as included in his address to the French information industry congress, IDT '93, in Paris during the month of June 1993.

[38] Mr. John Perry Barlow, Co-Founder of the Electronic Frontier Foundation, articulated this contrast during his address to OSS '92.

[39] Early on in my OSCINT advocacy days, I suddenly realized that too many of my former colleagues were confusing my advocacy of OSCINT as a foundation for all-source intelligence with a view--which I do not support--that OSCINT can do it all or can substitute for clandestine and technical collection. I am fond of the analogy that Dr. Joseph Nye uses (he was until recently the Chairman of the U.S. National Intelligence Council). Dr. Nye talks about the intelligence problem as a jig-saw puzzle, and of open sources as the outer pieces of the puzzle, without which one can neither begin nor complete the puzzle. Clandestine and technical collection comprise the inner pieces. Dr. Nye would probably agree with my proposition that open sources have become a larger part of the solution in recent years--he might be reluctant to agree with my proposition that one often does not need the classified pieces in order to make a decision, and that in fact the maintenance of operational momentum is often is direct contradiction to the intelligence community's

Diamond versus Linear Paradigm. The old paradigm for information acquisition is the linear model, where the consumer goes to the analyst who goes to the collector who goes to the source, and then back up the chain the answer goes. This paradigm is not only too slow, it is not workable when you have a fast-moving topic with lots of nuances that are difficult to communicate to intermediaries. The new paradigm is the diamond paradigm, where the consumer talks to the analyst, the collector, and on many occasions the source, in order to ensure there is a timely and accurate meeting of the right minds[40]

CIO = Corporate Intelligence Officer. The last person corporations should appoint to the CIO position is the oldest information systems expert. They are technicians and do not have the slightest understanding of corporate strategy and the needs of senior executives for real-time *content* displayed in meaningful ways. The CIO position should not only be responsible for ensuring that the entire corporation--every employee--serves as part of the collection network, but also for ensuring that the information in hand is exploited, and that the corporation has the broadest possible network of external collection and processing capabilities on demand. The CIO should be the intelligence community's primary point of contact for legitimately and openly exchanging unclassified information.

Information Value: content + context + time. Corporations and banks have a wealth of information that is rotting away unused rather than being bartered or made available to one another as a means of increasing the competitiveness of an industry or a country. If

---

propensity to delay and delay in the hopes of getting a perfect answer. In forming my judgement on what best meets the need of my military commanders, I am influenced not only by many discussions with officers at the Warfighting Center of the Marine Corps, but also by Brigadier Richard E. Simpkin's excellent book, *Race to the Swift: Thoughts on Twenty-First Century Warfare* (Brassey's, 1985).

[40] I developed this concept while considering how relationships have changed between consumers, analysts, case officers, and clandestine agents. Those that do not actually understand the capabilities and limitations of clandestine intelligence frequently fall victim to the myths of clandestinity, and fail to understand that both agents and case officers are human. Too often, an agent will fabricate information or take information from open sources and pretend it comes from a "third cousin working for the Foreign Minister" to avoid any appearance of diminished access, and too often, a case officer will accept a fabricated answer either for lack of time to validate the information, or out of naivete. The number of case officers that do not read the local press or understand the local language at a level of competence sufficient to detect nuances and dissembling is distressing. Now, with so many open sources and so many experts being brought "on line" through the Internet and other means, it is my view that the role of the analyst is changing dramatically. Instead of evaluating analysts on the basis of their ability to master a limited amount of classified data, we must now begin training our intelligence analysts, and evaluating them, on the basis of their ability to identify and exploit an almost infinite range of external human sources.

one understands that stripping information of time and context allows it to be bartered without losing a competitive advantage, while gaining additional information in the process. then the way is open to operational-level agreements which will increase an individual firms competitiveness as part of a larger consortium. The intelligence community should be the catalyst for a national program to inventory existing information that is in storage or available through private enterprise collection networks, and then devising means of accelerating the transfer of basic information to the information commons.[41]

Information-Driven Actions are better than mission-driven actions. Many corporations as well as government organizations appear to be mired in old organizational practices where a business unit is given a specific series of tasks to accomplish, and is then expected to accomplish those tasks over and over again without reference to the external environment or other elements of the corporation.

Corporate Hive. Every employee is a collector, producer, and consumer of intelligence. Drivers of delivery vehicles, service technicians, those responsible for cold calls on customers, all should receive special training in observation and elicitation, and should have easy to use channels and processes for reporting what they see and hear. At the national level, the concept of "national hive" merits pursuit.[42]

In brief, then, we must think of each organization within the information continuum as an information network, with each citizen-employee being in turn responsible for exploiting those external information networks that they come in contact with--quite literally, <u>everyone</u> becomes a collection and producer of intelligence.

<u>Private Enterprise Intelligence--Tactical Opportunities</u>

Now here are some tactical specifics--these are representative examples of capabilities that you could be using today--if you are not, you simply are not getting the best private intelligence possible.

---

[41] This concept of value probably owes something to a number of readings in cybernetics, but no single reading stands out. It was articulated in my paper on "ACCESS:....", *supra* note 25.

[42] See Kevin Kelly, *supra* note 16, *passim*. Kelly's book will be hard going for the average intelligence officer, but at the management level it is well worth the effort. The concept of gaining control over a $500 billion a year private enterprise intelligence continuum by <u>giving up control</u> of the fraction of intelligence resources necessary to nurture distributed centers of excellence is one that will be difficult to accept for the current generation of senior intelligence managers, but one that will inevitably be implemented within the next five to six years by the incoming leadership.

I want to stress that reliance on a single provider of private enterprise intelligence and information services is no better than having an in-house capability--the greatest returns on your investments in tactical intelligence will come when you have the ability to "mix and match" sources and services from across the entire information continuum, hiring the very best experts on very narrow topics for only as long as needed, but with the assurance that the information they provide is first-hand, in-depth, and not only current, but in fact ahead of the published record.

It is also important to note that the non-profit arena, and particularly libraries, are discovering that they can exploit existing infrastructure, and cheap student labor, to compete with commercial online services. Across the information continuum, capabilities and limitations are in flux, with new and lower cost capabilities emerging every day.

Figure 4: Basic "Intelligence" Capabilities in the Non-Profit Arena

Tony Rutkowski, Executive Director of the Internet Society, also oversees publication of a professional journal loaded with information about resources on the Internet, and understands better than most the technical issues associated with making global information available to any business. I am a member of the Board of Advisors of the Internet Society, and one of the things I am encouraging is a new focus on distributed content--on establishing a structured understanding of what comprises the "virtual library" or "virtual university" which is connected by Internet links.

Brewster Kahle, formerly with Thinking Machines, is the genius that invented the Wide Area Information Server (WAIS), which is now a standard for rapidly searching the entire Internet for weighted (relevancy ranked) full text documents. Brewster can tell you what businesses are doing to take advantage of the Internet, including their collection and search strategies. WAIS, and now the World Wide Web, enable an intelligence organization to constantly assess what is available on the Internet for any given topic, and to rapidly access

specific documents *and specific subject-matter experts.*[43]

Chris Berendes is a Master Inter-naut whose specific expertise is seeking out scientific & technical information of business value from all over the Internet.

One comment on the Internet: it eats people. It is much better to have a single Internet specialist, or to contract out searches, otherwise employees run the risk of either becoming hopelessly lost, or hopelessly addicted to wandering in cyberspace.

Geoffrey Fox is the man behind Syracuse University's "InfoMall". This is a good example of a university recognizing that it can substitute support to business for declining students as a source of revenue. He provides multi-media "intelligence" to businesses.[44] It is

---

[43] The economics of information, and the protocols associated with "tapping into" distributed expertise, are in great flux. Among those who are well-established within the Internet community, there is an understood barter economy as well as understood rules of behavior which preclude blatant exploitation (or even imposition of traffic upon) acknowledged experts. One of the most inconvenient things to happen to me is to have been listed in a new book, *E-Mail Addresses of the Rich and Famous.* While I am neither rich nor famous, my status as a former spy led to my being exploited by the publishers of this book, with the result that I must now deal with inquiries from people who have nothing better to do than send electronic mail to people they do not know. My rule of thumb is that I will give serious inquiries one free response--after that I charge $200 an hour. Once small digital cash exchanges become a matter of routine on the Internet, I anticipate much more *ad hoc* consulting and self-publishing. One of the reasons that TELTECH and BEST America are doing so well is that they provide three essential services: they pre-screen experts for quality; they obtain non-disclosure agreements; and they handle billing and compensation. The private sector can be expected to develop many more clearinghouses and "expert on demand" capabilities meeting the needs of the intelligence community.

[44] Although intelligence communities have in the past exploited their universities, largely through directed contracts funded, in the United States, by "External Research & Analysis" (ER&A) funds, with the fiscal decline these funds have been among the first to be cut, a strategic error on the part of intelligence community management. It is far more productive to cut vertical slices of classified programs than to further distance the intelligence community from private enterprise intelligence capabilities. At the Advanced Information Processing and Analysis Steering Group (Intelligence Research and Development Council) Symposium in March 1993, one senior intelligence community officer lamented the fact that 80% of the information technology dollars go to maintenance, and that the installed base is dragging the whole program down. That is precisely the problem--the community needs to transition from an era of large centralized installed bases, and into an era where a core of dedicated analysts with the finest possible tools exploit private enterprise intelligence capabilities to the fullest extent possible--and only if the private sector cannot to meet the consumer's needs, should a

also a good example of how shared computing resources, and part-time university talent, can meet needs which the business and government communities might not be able to afford on a "full-time" or dedicated basis.

University of Michigan Clearinghouse for subject-oriented Internet resources is a classic example of graduate students doing something useful for the business community. Among the directories they have prepared are ones for aerospace engineering, government sources of business and economic information, and so on.

Economic Bulletin Board Service operated by the University of Michigan provides a number of useful files including statistical information, press releases from the U.S. Trade Representative, defense conversion information, East European trades leads, and so on.

I am convinced that universities, especially now that they are confronted with declining student populations, have a very important role to play in the provision of practical tactical intelligence support to corporations and governments. Adopt a university in order to harness the brainpower of their graduate students, and the connectivity and power of their electronic resources.

Brenda Bailey at Uncover Reveal is the tip of the Colorado library association that may put some of the commercial online services out of business. They are using existing library overhead to index and abstract, and then supporting their library services through on-demand faxing of materials for which fees are charged. Here is a simple example of their service: they distribute, at no cost via the Internet, the tables of contents of the journals they process. Any intelligence community analyst can receive, for free, exactly those tables of contents that are of interest to them--and they can either order copies of articles of interest from their government library, or--perhaps more efficiently, at a nominal cost from the University of Colorado.

Special Libraries Association takes care of the many corporate and academic special libraries, and in essence nurtures a wealth of information that is not mainstream but is very much at the heart of our national competitiveness. They are the private intelligence service for esoteric issues. They have been in existence for over 84 years, and specialize in helping librarians tap into international corporate libraries and other specialty collections.[45] The

---

revitalized clandestine or technical intelligence capability be called upon.

[45] One of the things that most impressed me during my March 1994 visit to Singapore, where I was welcomed by the National Computer Board (27 years olds with 140+ Intelligence Quotients, acting as a very effective shadow government), was their strategic plan to link government databases in the near future, *followed shortly by the linking of banks and private enterprise databases*. Obviously proprietary information and multi-level security issues will have to be sorted out, but I fully expect Singapore to be among the first three

Canadian equivalent of this organization should be an integral part of the national strategy for harnessing the enormous power resident in corporate libraries and databases.

Corporate and other private libraries are a critical national resource, and there should be a national program which facilitates "inter-library loan" sharing, as well as digitization of materials of common interest. My friend Paul Strassmann developed the concept of Corporate Information Management (CIM).[46] CIM means "one time data entry, corporate wide access". I have extended this concept to include National Information Management (NIM) and Global Information Management (GIM), and am convinced that the next major advance in the intelligence field will be the development of robust unclassified burden-sharing arrangements between governments and their private sector partners, and between governments acting on behalf of their private sectors....and of course in the private sector there are already numerous strategic alliances for information sharing.

Library-Oriented Lists on the Internet were put together by Charles E. Bailey, Jr. He is Assistant Director for Systems, University Libraries, University of Houston. He is Co-Editor of *Advances in Library Automation and Networking*, and Editor-in-Chief of *The Public Access Computer Systems review*. He understands the role libraries have to play in national competitiveness, and the importance of networking.

"smart nation-states" in the world.

[46] Mr. Paul Strassmann is perhaps best known for his recent service as Director of Defense Information in the U.S., where he managed the world's largest information empire. Previously he has served in a number of executive positions, including Chief Information Officer of the Xerox Corporation. Among his recent books pertinent to the creation of national information architectures are *Information PayOff: The Transformation of Work in the Electronic Age* (Free Press, 1985), *The Business Value of Computers* (The Information Economics Press, 1990), and *The Politics of Information Management: Policy Guidelines* (forthcoming).

Figure 5: Core Business/Economic Intelligence Capabilities

David Young founded Oxford Analytica, and this is, in my judgement, the finest global intelligence service that is open and private. He was a National Security Council staffer with Kissinger, and decided he could do better than what CIA was providing to the President. He enlisted the Don's of Oxford, and now provides the business community with daily intelligence and special reports that have earned praise from the World Bank and others. *Oxford Analytica runs 750 legal, overt human assets world-wide, trimmed down from an original 2,500 contract assets.*[47]

WONG Chiu-Yin runs *The Economist* Intelligence Unit, based in New York. They provide intelligence reports and special consultations to businesses world-wide, and there is a good reason why they are called an Intelligence Unit.

Joe Casitore is the Vice President for New Business Development at FIND/SVP in New York. This international firm will obtain any published document, including what we call gray literature (documents published in limited numbers by private parties, but not classified or proprietary). FIND/SVP also runs an "ask any question" service that is mainstay of the private intelligence business, and it has a strategic research division.

Ruth Stanat represents the best of the new private intelligence breed. She has an international company with correspondents all over, and she does a very fine job of both market research, and forecasting. Together with Herb Meyer and Kirk Tyson in Chicago, Ruth is among the best in the privatization of intelligence. David Young is my hero because he has a network of 750 agents worldwide, and does intelligence every day about every topic; Ruth does research on demand, but I believe she is a great deal more competent and more trustworthy than most private detectives and more globally tuned in than many information brokers. Ruth is also the author of the excellent book *The Intelligent Corporation: Creating*

---

[47] Every morning, the staff of Oxford Analytica meets, bringing together its area officers (one for each major region) with a changing mix of Dons. The area officers come to the morning meeting after a lengthy review of all over-night wires and news services. In collaboration with the Dons, they ask and answer three questions: a) where is the news wrong, and must be corrected for our clients? b) where is the news right, and must be elaborated upon with technical or other detail for our clients? and c) what weak signals are we starting to detect, that might allow us to make a useful forecast of coming changes for our clients? After deciding what issues to address that day, a limited number of their world-wide human network are mobilized. A typical example: a Chilean economist, friends with the Minister of Trade, is asked for a report. Within four hours he provides a two page report suitable for a President or Prime Minister, based on direct sourcing to those in positions of power. The World Bank complimented Oxford Analytica in writing, for being the only private enterprise to correctly forecast economic developments in Russia when it was transitioning from Gorbachev to Yeltsin.

a Shared Network for Information and Profit.

Herb Meyer is a good example of a "private spy" (in the new sense of legal open intelligence, not the old sense of industrial espionage). He was editor of *Fortune*, then Vice Chairman of the National Intelligence Council, and is now CEO of Real World Intelligence. Inc. He is the author of author of *Real World Intelligence: Organized Information for Executives*. Herb is a success story, and has translated lessons learned in the classified intelligence community into a competitive advantage in the private sector.

Dick Klavens is the President of the Society of Competitor Intelligence Professionals (SCIP). These are the people around the world whose specific job it is to collect, process, and disseminate corporate intelligence. They are the "in-house" managers of corporate-wide collection plans, cross-business unit intelligence sharing, and--when needed--the hiring of external information brokers, telephone surveyors, and the occasional (rare) private investigator. Their annual symposium, together with that of the Association for Global Strategic Information (AGSI). and that of the Association of Information and Dissemination Centers (ASIDIC), as well as my own, are "must attend" events for anyone who wishes to be follow the latest open sources & methods in the information age.[48]

LEXIS/NEXIS, besides being a good all-around tool for research, is a good way of identifying experts and finding those journalists and professionals who are thinking about publishing the latest developments in specialized areas of interest.

TELTECH Experts on Demand are part of the private intelligence community, but they can also tell you about their customers. They have 3,000 technical experts on call. and can put a customer in touch with one over the telephone, with the result that "real-time intelligence" is produced when needed.

BEST America is similar to TELTECH, only they have 40,000 experts on line, and specialize in the life sciences. Pharmaceutical companies pay serious money to be able to reach out and tap into very narrow expertise on a moment's notice and with the assurance of total discretion.

---

[48] SCIP's symposium, including a number of excellent pre-conference tutorials, is generally held each April, and moves from city to city and attracts 500-700 participants. SCIP is actively expanding its international membership. AGSI meets in Europe and attracts 50-100 corporate strategic planners and business intelligence specialists. ASIDIC meets twice annually in the U.S. and attracts 50-100 of the leaders of the U.S. information industry. I consider ASIDIC to be the elite information industry association. The OSS symposium, the only symposium in the world where spys, hackers, information brokers, and corporate buyers of information services come together, is held in early November each year, always in Washington, D.C., and attracted 629 people in 1992 and 808 in 1993.

I want to emphasize the value of external experts. This is important because anything that is printed is by definition out of date. Books are seven to ten years out of date, articles are 7-10 months out of date, and even daily newspapers stories are a few days old. In the age of information, when speed is a factor in competitiveness, you can get ahead of the mainstream by using experts to create information and give it to you before it is published. Any research which does not commission original thinking and include some telephone surveys with real people is not optimized for advantage. Getting to the best expert on a topic, rather than relying on a generalist searching the literature, is the only way to ensure your research is current.

The external experts are especially important as uncompensated filters and evaluators. They spend their lives, at someone else's expense, monitoring their respective areas of expertise. In addition to providing their own expertise, they can quickly guide an intelligence community analyst to exactly the right materials, which can then be acquired for independent evaluation and integration into an all-source product.

PRIVATE INVESTIGATORS	Kroll Associates (New York) (212) 319-0044	Fairfax Group (Washington, D.C.) (703) 207-0600	Parvus-Jerico (USA-Bermuda) (301) 589-4949

Figure 6: More Intrusive Private Intelligence Capabilities

Kroll Associates (New York) has received favorable publicity as a leader in offering trade secret protection and related private intelligence services. Across the private investigative and "executive services" community, they are the one constant when credible, reliable, international capabilities are discussed.

Fairfax Group (Washington, D.C.) provides a range of services from financial investigations of takeover targets to debugging of offices and handling of ransom negotiations for executives.

Parvus-Jerico (USA-Bermuda) is run by Jerry Burke, former Executive Director of the President's Foreign Intelligence Advisory Board in the U.S.A., and does especially well in the Caribbean and Latin America.

Reva Basch. Author/editor of *Secrets of the Super Searchers*, this lady is widely

regarded as the god-mother of online searchers. A founding member of the Association of Independent Information Producers (AIIP), Reva is respected everywhere--she also has a very strong commitment to ethical guidelines, and believes (and proves every day) that the best private intelligence can be acquired legally and ethically at relatively low cost.

Seena Sharp is one of those hard-core New York sharpies transported to California, with a great sense of humor and the ability to do whatever it takes (legally) to get you what you want. She also is one of the founding members of the AIIP.

Helen Burwell is the best organized of the independent information brokers, and publishes the *Burwell Directory of Independent Information Brokers*. She knows everyone, knows their strengths and their weaknesses. At my suggestion she recently surveyed all independent brokers for their foreign language and foreign database/resident experiences, and her directory now opens windows into the foreign environment.

Information brokers are very special people. Most companies make the mistake of using a single broker, when in fact there is an entire range of brokers who specialize in very specific areas. Helen's directory is the perfect window into this marvelous global community of very talented people.

In the classical intelligence arena, there are a few people in the Anglo-Saxon community (I am not yet familiar with the Asian and Latin communities) who conduct classical intelligence operations on a for-hire basis. The three I have selected are simply representative.

Rapport Research & Analysis has strong roots in the SAS and British intelligence community, and specializes in using ethnic cut-out career agents to securely handle tailored networks in any country. They are also capable of developing rapid-response teams of linguistically qualified interrogators and debriefers who can exploit resident immigrant populations to quickly develop both operational leads and positive intelligence on other countries, organizations, and personalities.

Aerobureau Corporation has a very nice air-breathing surveillance aircraft and a program to provide "Strategic Television Airmobile Reports via Satellite" (STARS). The four-engine aircraft includes a remote-controlled drone that can take videos over denied or dangerous areas. Although focused on imagery, they could also be equipped with rapid-response signals equipment, to include fax and telex intercepts.

OPEN SOURCE SOLUTIONS, Inc. is an umbrella organization which specializes in knowing who is "best-in-class" for any given requirement at any given time. It provides open sources, systems, and services that are legal, ethical, discreet, responsive, and relatively inexpensive. This can include everything from simple on-line searches to complex telephone surveys, from document acquisition to human network development to real time imagery delivery. The whole point of a clearinghouse is to relieve the customer of the burden of

finding the correct private enterprise intelligence capability, while also "laundering" the customer's requirement by concealing its origin and context, and providing the customer with a quality-control guarantee. Founded originally as a non-profit organization to push U.S. policy, OSS, Inc. has responded to international demand by repositioning itself as a for-profit capable of delivering any open source, system, or service.

Conclusion

In the information age, "intelligence" is less a matter of penetrating secrets, and more a matter of separating useful information from the flood of open information that is available legally and cheaply, *in order to provide "just in time" decision-support to the consumer.*

In a period of rapidly changing and emerging threats, when fiscal resources for national intelligence are in decline, open sources are proving to be far more capable and responsive than any intelligence analyst would ever have expected, and cost a fraction of their classified counter-part disciplines.

The private sector is a Nation's first line of defense, and also its first line for collection and processing. It is the private sector which offers the cheapest and fastest indications & warning, current intelligence, and even estimative intelligence capabilities.

The concept of "central" intelligence will simply not survive. "National intelligence" must be redefined, and the intelligence community reinvented, in order to harness the distributed intelligence of the Nation, while permitting the intelligence community to conserve its scarce resources. The intelligence community must focus on satisfying a broader range of consumers, on outsourcing collection and analysis to the maximum extent possible, *and on developing clandestine and technical collection capabilities that are truly discreet and able to achieve results without exposure.*

National intelligence communities cannot remain isolated entities relying solely on in-house capabilities funded by the tax-payer. Without a national information strategy, and national vehicles for harnessing the distributed private enterprise intelligence capabilities of the nation (and of other nations), national intelligence communities are at risk of both a 50% cut in their budgets (or worse), and relegation to an obscure role as special action teams restricted to *in extremis* tasking.

The bottom line, however, remains the consumer of intelligence. Today's consumer is sophisticated and constantly exposed to the wide variety of private enterprise intelligence capabilities. Today's consumer is also beset-by fiscal constraints, and it will not take the consumer long to realize that there may be some advantages to "raiding" the intelligence community's budget in order to "distribute" intelligence resources among the consumers themselves. If the intelligence community does not master OSCINT and provide the consumer with a "value-added" contribution in relation to OSCINT, then the day is going to come when the consumer will testify to Parliament that they do not read classified

intelligence, they do not want classified intelligence, or are not willing to pay for classified intelligence. On that day, intelligence as we know it will die.

It is our burden and our privilege to work together to ensure that from the ashes arises a new form of national intelligence, a national intelligence which fully integrates and harnesses the distributed capabilities of each Nation, and serves as the foundation for national security & national competitiveness. Together, in combination, the unclassified capabilities of private enterprise intelligence and those of classified government intelligence can form a "virtual intelligence community" without equal, a virtual intelligence community able to simultaneously inform policy-makers, business, the academy, and citizens.

Executive Summary

Point #1: In the Age of Information, "intelligence" is less a matter of penetrating secrets, and more a matter of separating useful information from the flood of open information that is available legally and cheaply: *electronic sources are especially useful.*

Point #2: In combination, the economic and political cost of industrial espionage, or penetrations of other governments to divine "plans and intentions", are insupportable when contrasted with the benefits of open source intelligence (OSCINT).

Point #3: The concept of "central" intelligence cannot survive in the Age of Information. By focusing on OSCINT, a Nation can mobilize each of its knowledge sectors, and turn the entire Nation into a "virtual" intelligence agency with far greater collection. processing, and action capabilities than are provided by the existing bureaucracies dedicated to national and defense intelligence.

Point #4: Comprehensive national knowledge strategies must provide for connectivity, content, culture, coin, and C4 security: the "Five C's".

Table of Contents

1 Background. What is the issue; changed "rules of the game"; national information continuum; four information categories; three characteristics of value; speed as the foundation of security; hard copy versus electronic information.

2. Discussion. Role of intelligence and "virtual" intelligence; information as a substitute for capital and labor; possible investment strategy for information; political and economic cost of espionage; pre-publication/pre-secret windows of opportunity; speed advantages of open source exploitation.

3. Information Requirements and Player Identification. Priority versus gaps-driven collection; four major consumer groups of intelligence; refining the gaps-driven requirements process; model for consumer-oriented production; four major target groups for intelligence; four kinds of players in the open source arena.

4. Sources of Information and Methodology. Five distinguishing aspects of information sources; essential reorientation of intelligence toward open sources; privatization of intelligence; five elements of a national knowledge strategy.

5. Industrial Espionage, Sanctions, and Proscribed Information. U.S. views of Japanese and French; general attitudes about industrial espionage; sanctions; proscribed (prioprietary) information.

6. Analysis. Rules of the game have changed; competitive advantage has shifted from secrecy to openess; new "order of battle" needed for national intelligence; national knowledge strategy is a critical initiative; strategic opportunity for competitive advantage exists.

7. Action Requirements. Reinvent national intelligence; realign resources; establish a national information requirements council; establish open source focal points within United States and other countries.

8. References. Resume and selected publications; other works of importance; date of information.

1. **Background**

What is the issue? The issue of access has enormous importance for both the national security and the national competitiveness of any Nation.

> *The issue for the client is: how does a Nation achieve national security and national competitiveness in the Age of Information, and what does this mean to existing national policies on intelligence organization and the expenditure of public and private funds for information collection, processing, and dissemination activities.*

Changed "Rules of the Game. An understanding of the "sources and methods" which comprise "access" in the Age of Information is absolutely vital for top-level decision makers in both government and the private sector. Top-level decision-makers must understand that the "rules of the game" have changed, and that competitive advantage in the

Age of Information is dependent on the laws of cybernetics, not the laws of physics. Under the laws of physics, secrecy and the restriction of knowledge provided a temporary advantage. In cybernetics, openness and flexibility win.

Most great nations spend on the order of $20 billion to $30 billion a year on "intelligence", which is traditionally comprised of clandestine human intelligence, and technical collection of imagery and signals.

National Information Continuum. At the same time, most great nations have an "information continuum" (illustrated below) whose endeavors and products are going to waste...the capabilities of these elements of the national information continuum are not being exploited! This continuum represents, in a typical great nation, a $100 billion per year capability that is lying fallow.

Universities Business Media Defense

Figure 1A. The National Information Continuum--Nine Sectors

NOTE: The above is an original representation that has been current in the literature for over a year. It is different from the more practical Sector Breakout because it reflects a focus on elements of the information continuum which do not--at this time--contribute significantly to national and defense research endeavors.

Four Information Categories. There are four "information categories" in the access arena. They are:

a. Open source or public information: within intelligence communities, this is known as open source intelligence or OSCINT. "Grey literature", literature which is unclassified and not proprietary, but produced in limited quantities for limited purposes, is included as an element of OSCINT. Open (unclassified) electronic information, such as that available through the INTERNET and related file servers and newsgroups, is also included in OSCINT. *The vast majority of scientific & technical intelligence is available through OSCINT, to include 600 scientific & technical journals that appear only in electronic form.*

b. Open proprietary information, discernable through open source investigation. This includes the reverse engineering of legitimately acquired products, and legally conducted "competitor intelligence". (Note: competitor intelligence is the globally accepted term for legal research efforts by businesses studying their competitor's products, organizations, and related matters.)

c. Closed proprietary information, available only through industrial espionage or

clandestine and technical penetrations of regulatory agencies.

d. Classified information, available only through clandestine human intelligence or technical (imagery or signals) intelligence.

Open Sources	Proprietary (Open)	Classified
Grey Literature	Proprietary (Closed)	

Figure 1B. The Four Information Categories

Three Characteristics of Value. The value of information is derived from three characteristics of the information: its substance or content; the context within which it is being considered by others; and the timing with which it is received.

> *The single most significant step an organization can take to increase the value of the information it is acquiring is to increase the speed with which the information is acquired and acted upon. This is also the most inexpensive step--but only if top management is willing to accept significant changes in doctrine and procedure.*

Speed as the Foundation for Security. The speed with which information moves and achieves value depends less on the information itself (the externality) and more on the degree to which the participating organizations are organized and aware of their requirements (the internality). Organizations are drowning in information because they have not learned to swim. They are not trained, equipped, or organized to collect, process, disseminate, and act upon information. The most important employees, the ones with the contextual understanding of the situation, are normally not empowered to act on information, and normally do not receive intelligence products.

Imbuing a national infrastructure with "speed" really means that a complete change is required in the way in which organizations relate to one another, and in the way in which managers relate to front line workers or action officers. The beauty of working with open sources is that it eliminates, in a single stroke, all of the political and legal, as well as the economic, constraints that characterize the sharing of classified information. We have been trying to water the desert with oil, instead of water.

Hard Copy versus Electronic Information. Finally, in discussing issues of access, it is important to understand the relative value of hard copy versus electronic information. Although hard-copy information far outweighs electronic sources in quantity, and particularly in relation to Third World sources, the electronic world is where "up and coming" technologists as well as "up and coming" leaders are communicating their most signficicant thoughts.

The electronic world is especially useful because it allows an enormous amount of research to be conducted from a single location, and also allows relatively anonymous browsing through other computers or commercially available databases. Hard-copy is an important secondary source, especially when investigating Third World and non-technical issues.

Third World Hard Copy "Cyberspace"

First/Second World Hard Copy INTERNET

Figure 1C. Hard Copy versus Electronic Information

2. Discussion

Role of Intelligence and "Virtual" Intelligence. There is no issue more important to a Nation in the Age of Information than that of the role of intelligence--not only of the role of the traditional national intelligence services, but also of the non-traditional "virtual" intelligence services which are represented by the other elements of the national information continuum.

> *A proper perspective on this matter, at the highest levels of both the government and the private sector, represents at least a $100 billion a year value. This is enormously important, not only because it will be the major policy area affecting the future of the Nation, but because it is relatively easy to achieve by realigning and coordinating existing capabilities and funds.*

Information as a Substitute for Capital and Labor. In the Age of Information, when information is the "first order" commodity, and information is a substitute for time, space, capital, and labor, the implications of this discussion are enormous. The fate of the Nation depends on a proper appreciation of this issue, and on adequate coordination between government and private sector leaders responsible for elements of the information continuum.

Possible Investment Strategy for Information. The four "information categories" in the access arena can be evaluated as follows:

-- Open source: 80% of what is required for sound decision-making, at 20% of the cost, in 20% of the time (relative to industrial espionage or classified collection). The value of open source information cannot be exaggerated.

-- Proprietary (open): 5% of what is required, for an additional 10% cost increment.

-- Proprietary (closed): 5% of what is required, for an additional 20% cost increment.

-- Classified: 10% of what is required, for an additional 50% cost increment.

|----------OSCINT (80%)----------|

PROPRIETARY (10%)
CLASSIFIED (10%)

Figure 2A. Possible Investment Strategy for Information

Political and Economic Cost of Espionage. It merits comment that industrial espionage in particular, but clandestine and technical intelligence as well, reflects a political risk, or a potential political cost, that is easily triple the economic cost--industrial espionage and classified penetrations are not only twice as costly as open source exploitation, they are also twice as likely to "explode" in the face of their sponsor.

Pre-Publication/Pre-Secret Windows of Opportunity. In the area of open source information, or open source intelligence (OSCINT). it is very important that decision-makers understand the levels of access in terms of time
--time is the vital aspect of cybernetics, and is the critical factor in national competitiveness:

Published sources are available to mass audiences at the same time--books are generally provided to the public years after they were actually written; articles generally months after they were written; and newspaper reporting days or weeks after being drafted..

"Grey literature" is available to specialized audiences at the same time. and to non-members after a period of time.

"Work in progress" in available to peer review groups and to specially equipped "outsiders".

"Pre-publication intelligence" is available to specially equipped outsiders who take the trouble to identify and cultivate selected sources of public information. This area is the "center of gravity" for those who seek to "reinvent" national intelligence.

Speed Advantages of Open Source Exploitation. There are two reasons why open source intelligence (OSCINT) is a vital area of concentration: the first is that most applied technology, including proprietary or classified technology, begins with open publications about its sub-elements, and it is often possible to piece together very good intelligence reports "at the source" while avoiding the risk of industrial espionage or clandestine operations against foreign targets. The second reason is that every "dual-use" technology to which export controls are eventually applied spends at least two years, and sometimes up to ten years, in "beta" development. The Department of Commerce, which has the lead in classifying dual-use technology, is generally two years behind actual market developments; this is particularly true in the software arena. Thus, the best time to capture a "secret" or a restricted technology, is during the two year "beta" window before it becomes a secret or is

restricted.

Real-Time Mind Link Beta Testing Traditional Sources

Work in Progress Gray Literature

Figure 2B. Speed Advantages in Open Source Exploitation

Refining one's open source intelligence (OSCINT) intelligence process to collect information in the pre-publication stage, by identifying and keeping in touch with key experts who provide advance looks at "works in progress", adds a further six months to a year of competitive advantage. *Electronic searching is the single most vital tool in identifying these experts "in time".*

3. Information Requirements and Player Identification

There are three ways of looking at the information playing field: by focusing on the four consumer groups for national intelligence; by focusing on the four warrior classes of the future; and by focusing on the sources of information. Each will be discussed in turn, together with a means of executing gaps-driven collection and consumer-oriented production.

Priority versus Gaps-Driven Collection. The information requirements arena is traditionally one which intelligence communities have not mastered. Too often they collect what is collectable, or obviously protected, and they rarely produce intelligence that is tailored to a specific customer or delivered "just in time". Information requirements are typically driven by gross priorities (e.g. the Soviets are priority one, the Chinese priority two), rather than by "gaps" or real requirements. This often means that Third World encyclopedic intelligence (most of which is unclassified), and economic or demographic intelligence vital to penetrating foreign markets, does not receive the attention it requires.

Four Major Consumer Groups of Intelligence. There are four specific groups of information customers that every intelligence organization should be serving, but generally does not, because it focuses on the very highest levels of government rather than on the subordinate levels where policy is actually created and actions are taken on a day to day basis.

a. Departmental planners and programmers, in every Department of government, not only in the national security arena, require both strategic generalizations (rather than a flood of detailed reports about tiny parts of many problems), and political-military information heavily laden with information about "plans and intentions".

b. Regional planners and programmers, including Ambassadors and Assistant Secretaries of every Department of government, require regional generalizations and very detailed mobility and market information. This is the customer group most likely to take

advantage of intelligence which focuses on opportunities for advantage, opportunities to prevent disaster or establish commercial gains before anyone else realizes there is a threat or an opportunity to be contested.

c. Ambassadors and corporate general managers in specific countries require both detail about the physical capabilities of their opponents or competitors, and very detailed evaluations of sustainability, availability, reliability, and or accuracy of competitor products. In the economic arena, intelligence about demographics and culture is more easily obtained, and more valuable, than internal corporate information about competing products. If you understand the BUYER's requirements, you do not need to collect every detail about competing SELLER's capabilities. This point merits elaboration: competitive advantage comes from satisfying the buyer, not from beating the opposing seller. It is far more important to understand every detail about what the buyer wants to buy, than attempting to understand opposing solutions.

d. System designers and project managers, and those at the most senior levels who make acquisition and investment decisions, generally receive adequate intelligence about technical details, but do not receive good intelligence (intelligence which is generally unclassified) about whether the system is really worth acquiring in terms of cost-value, competing means of meeting the requirement, cost of sustainability, and so on. For instance, most advanced nations have invested billions of dollars in fast-moving sophisticated systems and failed to establish the necessary communications and computer support to actually make those systems effective in the field.

System Designers Regional Planners

General Managers Department Planners

Figure 3A. Four Major Consumer Groups for Intelligence

Refining the Gaps-Driven Requirements Process. The greatest flaw in a priority-driven requirements process is that it is divorced from the day to day needs of the policy and action-level consumer. Priority-driven collection tends to err on the side of repetitive and "vacuum cleaner" collection against the highest priorities, and to completely disregard both encyclopedic and current intelligence requirements for targets which may be of a lesser priority in the "grand strategy" arena, but of vital interest at the operational and tactical levels. A gap-driven information requirements process will take its requirements each day (rather than through monthly or quarterly "priorities validation" meetings), both from the consumer of intelligence ("here is what I need to know tomorrow") and from the analyst ("here are the things I did not know in producing this report").

Model for Consumer-Oriented Production. The existing production model, at least in the United States, is based on "stove-pipe" production which is rarely as "all-source" as it could be (e.g. the National Security Agency produces reports drawn largely from signals

intelligence), and is also severely deficient because it focuses on specific countries, topics, or weapons systems--i.e. the production is defined by the target, not by the needs of the consumer. Below is illustrated a superior line of consumer-oriented products, most of which would be unclassified and whose contents would be primarily drawn from open sources of intelligence.

BASIC PRODUCTION: COUNTRY PROFILES. Integrate executive summaries for each of the four consumer groups, with brief encyclopedic intelligence summaries of each of the key industrial, geographic, and civil factors.

STRATEGIC PRODUCTION. Tailored products that focus on establishing *strategic generalizations* pertinent to specific mission areas (e.g. aircraft, automobiles, textiles), specific regions, and specific timeframes (generally long-term).

OPERATIONAL PRODUCTION. Tailored products focused on *regional generalizations* with a special emphasis on industrial areas within the region, on seasonal differences (whether terrain or trade), and on leadership character and demographics.

TACTICAL PRODUCTION.. For each industrial area (or industry area) both generalizations and specifics country by country, with emphasis on terrain, climatic, and civil constraints. It is only at this level that a consumer should have to deal with the level of detail which now characterizes most intelligence community products.

TECHNICAL PRODUCTION. Get away from system-specific production, and move instead toward industry-area production with regional and timeframe sub-sets. Focus on support to cost-benefit and trade-off decisions, not on the system in isolation.

Figure 3B. Model for Consumer-Oriented Production

Four Major Target Groups for Intelligence. There are four specific targets for information and intelligence activities; each of these target groups must be completely understood if a Nation is to maintain both its national security and its national competitiveness. Each target group has a different source of power, and a different way of training, organizing, and equipping itself for battle. Each requires a different intelligence approach and in essence a different kind of intelligence community. The traditional intelligence officer will not be competent against all four of the target sets--four different kinds of intelligence organizations must be trained, equipped, and organized for their specific target set.

a. The High-Tech Brute, similar to the United States of America, is that group which relies on expensive technical capabilities and hugh logistics trains. In industrial terms. this is the capital-intensive player.

b. The Low-Tech Brute, such as the narcotics trafficker or the Italian crime family. represents a "needle in the haystack" problem. In industrial terms, this is the labor-intensive player.

c. The High-Tech Seer, such as highly skilled and knowledgeable computer engineers. is comprised of both conglomerations of skilled individuals engaging in economic warfare, and single individuals, "hackers", able to penetrate advanced computer and telecommunications networks. In idnustrial terms, this is the brain-intensive player.

d. The Low-Tech Seer, such as the Islamic Fundamentalists, or Asian gangs in the United States, are those whose "weapons" are of a cultural or demographic kind, whose "command and control" system is comprised of the television and the pulpit--very difficult for a Western intelligence service to understand and address. In industrial terms, this is the labor union.

In each of these cases, using electronic sources of news and information provides a significant competitive advantage in terms of time, scope of review, and depth of understanding.

High-Tech Brute	High-Tech Seer
High-Tech Brute	Low-Tech Seer

Figure 3C. Four Major Target Groups for Intelligence

Four Kinds of Players in the Open Source Arena. The diagram in the "Background" section clearly identified the nine constituencies in the access arena. Naturally there are sub-constituencies (e.g. government is divided at the federal level into legislative, executive, and judicial, and also into federal, state, and local; media is divided into mainstream national papers, regional papers, niche journals, and technical newsletters).

In general terms, there are four kinds of players:

-- Those who talk to one another but are not influential, are divorced from practical military or commercial applications: the "ivory tower" academics. Spend 10% of your resources on this group.

-- Those who are influential but do not quote one another and contribute nothing substantial: the "bandwagon" journalists. Spend 10% of your resources on this group.

-- Those who are both connected to one another and influential--this constitutes the "mainstream" of current thinking. The downside of the mainstream is that is tends to reflect conventional wisdom rather than innovative or revolutionary thinking. Spend 20% on this group.

-- Those--and they are a small group--that are neither connected nor influential, but who are in fact the "up and coming" leaders in their disciplines. It is this group which not only represents the greatest potential value for a Nation, but which is the least protected! The only obstacle to exploiting this group is internal, it is bureaucratic! Spend 60% on this group. Although intelligence organizations are accustomed to thinking of this group as a source of "sleeper" agents, in fact it should be thought of as a source of "avant garde" thinking which is not only of enormous importance to international competitiveness and domestic security, but predominantly unclassified.

Mainstream (20%)	Up and Coming (60%)
Bandwagon (10%)	Ivory Tower (10%)

Figure 3D. Four Kinds of Players in the Open Source Arena

4. Sources of Information and Methodology

Five Distinguishing Aspects of Information Sources. Sources of information can be classified by medium, location, discipline, language, and level of classification.

The most pervasive medium is hard-copy information. However, most of the hard-copy information is of relatively low grade, and often not worth the expense of acquisition. Never-the-less, it cannot be ignored. Spend 20% of your resources on the hard-copy medium.

The next major medium is micro-fiche; although many organizations are phasing out their micro-fiche holdings, this remains an important medium, particularly in the patent and archival worlds. Spend 10% on this medium.

Electronic information is available through online services as well as offline products. It is important to emphasize that electronic information includes imagery (SPOT, LANDSAT) as well as signals (foreign radio and television broadcasts, unencrypted cellular telephones, facsimiles, and telex transmissions). It is also important to note that, despite the fact that electronic information is a relatively small arena of interest in relation to hard-copy and microfiche, it is "exploding" and already dominates many of the most advanced disciplines as the "medium of choice. For instance, this medium contains over 600 scientific journals online that do not appear in hard-copy at all. *The electronic medium is the battleground where strategic advantage can be gained at relatively low cost and with no political risk--it is open, it is pervasive, and it is not being exploited by other countries as well as it could be--*

this is a very important area. Spend 40% of your resources on this medium.

The most subtle storage medium is the human brain. No intelligence service will ever master the data entry or data collection problem. The most important capability any intelligence service can develop is that of establishing real-time mind-links between the customer and the best available source. The "intelligence minuteman" concept. first articulated in December 1992 at the First International Symposium on "National Security & National Competitiveness: Open Source Solutions", is the wave of the future. Spend 30% of your resources on this medium. Note that this medium provides real-time access to the other mediums--the human expert responsive to tasking can rapidly collect, process, and disseminate essential information from the other mediums, on demand.

It is important to note that in the Age of Information technology has made possible a radical shift in why and when one acquires information. It is now possible to train, equip, and organize collectors of information for "just in time" collection instead of "just in case" collection. Hard copy and microfiche were the dominant storage mediums under the old "just in case" paradigm. Electronic information, and direct access to an enormous global pool of oven human asseets are the dominant access mechanisms under the new paradigm.

The location of the information is both geographic and physical. Some information cannot be obtained without a personal visit to its location. Most information can be obtained remotely. through a telephone call or correspondence, and payment if necessary to the appropriate person.

> *A single researcher skilled at remote data acquisition for a particular region is more valuable than 100 clandestine case officers spread over ten countries. Physically the information might be part of a central filing system or a personal filing system. 80% of the time the information will be part of a personal filing system, which reiterates the critical importance of developing human paths to the information.*

Professional disciplines (e.g. physics, electro-optics) are the most global and well-organized structures through which to acquire information. Penetrating a professional association with global links is far more useful than penetrating a single government's nuclear facility, to take one example. Again, professional associations provide the human links and paths toward virtually any information--they are also the most likely to publish information before it becomes classified. It is futile to train intelligence professionals to pretend to be scientists. It is much more useful and cost-effective to provide existing scientists with the finest communication tools and travel budgets possible--they will absorb far more, and be able to report far more, than a few case officers working with a few agents of limited access.

Language skills cannot be ignored. English, French, Spanish, Japanese, Chinese, and Arabic are the most important languages, followed by Russian, Punjabi, Hindu, and Hebrew. Any international intelligence or information service which does not have at least 100 people

fluent in each of the most important languages, and at least 20 people fluent in each of the minor languages listed above, is not serious. Language translation programs (e.g. Global Link) are important aids, and can be used to reduce the time of translation for a typical document from eight hours to three. The importance of linguistic and cultural nuances should not be underestimated. The language of the consumer should be the language of production, even if this involves extraordinary cost.

Level of classification (in governments generally Confidential, Secret, Top Secret, and Codeword; in business generally Proprietary, Trade Secret, Executive Only) is the most misunderstood and over-rated basis for selecting information. Enormous amounts of money are wasted, and significant political risk is undertaken, to obtain information that is classified "secret" or "proprietary". This is a fundamental mistake which reflects a lack of understanding about how knowledge works in society, a lack of understanding of current trends in information sources and methods.

MEDIUM DISCIPLINE CLASSIFICATION

LOCATION LANGUAGE

Figure 4A. Five Distinguishing Aspects of Information Sources

Essential Reorientation of Intelligence Toward Open Sources. The methods used to obtain information should be appropriate to the sector of information generation that is being studied. Each of the nine sectors has information producers. Each nation has representatives of their own in sectors of their own. For instance, your own journalists are frequently the best means of approaching foreign journalists, and of monitoring the production and the human sources being used by foreign journalists.

The fundamental flaw in the "methods" of most intelligence agencies is that they attempt to acquire all information using their own personnel and clandestine or technical methods. Instead, they should leverage the other sectors of the information continuum, and establish a "virtual" intelligence community that is comprehensive. By focusing on open information and the open exploitation of individuals in all sectors, a Nation with a $10 billion intelligence budget can leverage another $90 billion in existing independent but exploitable "virtual" intelligence capabilities whose "overhead" costs are not being paid by the government. The electronic medium is the "lever that can move the world" and give the intelligence professional enormous access.

Privatization of Intelligence

The most fundamental change in "methods", besides moving away from investments in clandestine and technical intelligence capabilities, and toward investments in open source intelligence, is that of the privatization of intelligence. It is more efficient, most cost-effective, indeed, more discreet, to

utilize ad hoc private collectors and processors of information, than it is to use existing bureaucracies, including existing intelligence agencies and existing Embassies or local corporate offices overseas.

Five Elements of a National Knowledge Strategy. This focus on openness is extremely important because it means that the fruits of this open source intelligence effort can be shared directly with industry, the press, and the legislature, without the slightest political risk. For those who do not understand how "open" information can provide a competitive advantage, consider only how disorganized everyone else is--the first Nation to establish a national knowledge strategy which harnesses the full power of their information continuum will achieve an enormous competitive advantage as we enter the Age of Information. A national knowledge strategy is comprised for five elements:

a. CONNECTIVITY. Provide leading representatives within each sector with the telecomputing tools they require to keep in touch with their counterparts in all other countries, and with one another. At the same time, provide government and corporate intelligence analysts with the same tools, and provide everyone with incentives to communicate with one another.

b. CONTENT. Provide incentives to all parties to maximize the amount of information that they put "online"; the government can increase online information by testing new economic models (for instance, the "compound interest" model instead of the "single sale" model for compensating authors) and making appropriate adjustments to copyright and patent law. This is a two-way concept. It is not only important to increase the amount of foreign language material that is captured, translated, and placed online, but it is equally important that great emphasis be placed on exporting national intellectual products which have been fully and accurately translated into major foreign languages such as English, Japanese, and Chinese. In the Age of Information, "gunboat diplomacy" has been replaced by intellectual influence. The quality of a nation's intellectual output, and the degree to which it is made useable by others, will have a dramatic impact on the strategic position of the Nation.

c. CULTURE. Recognize the importance of accelerating the integration of ethnic populations and economically impoverished citizens. In particular, those ethnic groups which speak and read fluently the language of their adopted country, and the language of their former country, are priceless national assets which can be used as interpreters and translators.

d. COIN. A typical major nation wastes on the order of $2 billion a year just on end-user fiddling with personal computer hardware and software combinations. If all redundant and contradictory research & development were brought under control, just in the information technology arena, a typical major nation would probably save on the order of $10-20 billion a year.

e. C4 SECURITY. Every nation, and particularly the advanced nations of Europe

and the Anglo-Saxon world, is extremely vulnerable to the interruption of command & control, communications, and computing services.
Virtually every major antenna system, including the downlinks from the satellites, is completely unprotected. No nation has established a serious C4 security posture that recognized the degree to which government, military, and economic communications depend on a very vulnerable civil infrastructure. No nation has established an effective "cyberspace order of battle". This is the "Pearl Harbor" of the Age of Information, waiting to happen.

CONNECTIVITY CULTURE C4 SECURITY

CONTENT COIN (R&D)

Figure 4B. The Five Elements of a National Knowledge Strategy

5. Industrial Espionage, Sanctions, and Proscribed Information

U.S. Views of Japanese and French. There is a very strong perception within the United States that the Japanese view economic competition as "war", and that the French, while not necessarily viewing economic competition as war, are willing to engage in "unethical" measures including direct support from government intelligence agencies to specific Frnech companies. The book Friendly Spies: How America's Allies are Using Economic Espionage to Steal Our Secrets, while discredited in some circles, has done enormous damage to French interests in the U.S. The running joke about Air France seats being "bugged", very common in U.S. business circles, is a good sign of how deeply this book has penetrated the "psyche" of the U.S. business community.

General Attitudes About Industrial Espionage. Most U.S. companies do not have a full appreciation of how easily others can penetrate their organizaations, and most do not engage in significant industrial espionage. For instance, most U.S. companies have absolutely no computer security and no measures to protect their computers from external penetration. They are completely unaware of the ease with which computer screens and computer emissions can be captured from a van parked outside their building. There is a general sense among U.S. firms that industial espionage is "not worth it". There are two exceptions to this: the first is the hiring of executives and key employees from competitor firms, and the second is bribery, but only overseas.

Sanctions. The Toshiba case is a good example of the sanctions that might be imposed is specific instances when there is a public knowledge of violation, but in general the U.S. government will not publicize or act on cases of industrial espionage.

Proscribed (Prioprietary) Information. There is a strong trend in the United States toward openness. This is true of the government, where many "secrets" and many secret technologies are about to be declassified, and also of industry, where there is a growing understanding that the restriction of information imposes internal costs that may not be

warranted. In the case of specific chemical formulas or other "protectable" secrets, this may not be so, but in the case of general engineering practices, targeted markets, and so on, the general focus is on openness and staying ahead of the competition, rather than on protecting secrets.

6. Analysis

The client is better able to evaluate the applicability of this new theory and practice of intelligence to their needs, but on balance one must conclude:

"Rules of the Game" Have Changed. The Age of Information has redefined our concepts of war and peace, of national security and national competitiveness. The "rules of the game" have changed, and there has been a reordering of both power and the sources of power. Information is now a commodity, and the most important resource to any Nation.

Competitive Advantage Has Shifted From Secrecy to Openness. The Age of Information has destroyed the ability of individuals, organizations, and governments to control information or restrict the dissemination of information. It is virtually impossible to keep a "secret" in this day and age. Hence, the competitive advantage has shifted from those able to conduct research in secret, to those able to RAPIDLY exploit the efforts of others through openly available information collected "just in time".

New "Order of Battle" Needed for National Intelligence. The Age of Information requires a new "order of battle" philosophy within national governments and their major corporate sectors. The degree to which individual minds can be linked across sectors now becomes more important than the number of tanks one has--existing conventional forces can be immobilized, and existing industrial processes can be superceded, by relatively modest applications of knowledge. *The rapid development of competent electronic search & retrieval specialists, and particularly specialists in scientific & technical databases and newsgroups, as well as cultural matters, should be a national priority.*

National Knowledge Strategy is a Critical Initiative. Although there are several nations, including Japan, Sweden, Israel, and Taiwan (and their tribal villages world-wide) which are generally ahead of all others in their national knowledge activities, no nation has actually developed a national knowledge strategy nor harnessed the potential of its nine sectors in the information continuum--a continuum that constitute a "virtual" intelligence community of enormous power.

Strategic Opportunity for Competitive Advantage Exists. A strategic opportunity for competitive advantage exists. In my judgement there is about a two to five year window within which an organized national effort can reap enormous dividends. After that time many organizations will both realize the power of open information and start developing their own collection capabilities more fully, and public encryption will be widespread, introducing a "Tower of Babel" effect into the "electronic English" information commons that is just

beginning to appear.

7. Action Requirements

a. Reinvent National Intelligence. Each nation has an enormous store of non-traditional intelligence and information capabilities outside of government that are rarely called upon. Consider the potential of these non-traditional sources, and develop plans for the total mobilization of the nation's intellectual power.

b. Realign Resources. Roughly 80% of the existing intelligence budget could be realigned to open source intelligence (OSCINT) collection, processing, and dissemination, in close cooperation with the other elements of the national information continuum, who might be inspired to effect their own realignments once they see the government in a leadership role.

CLASSIFIED INTELLIGENCE			**10%**
PROPRIETARY INTELLIGENCE			**10%**
OPEN SOURCE INTELLIGENCE			**80%**
Human Sources		30%	24%
-- "Up and Coming"	60%		24%
-- Mainstream	20%		08%
-- Bandwagon	10%		04%
-- Ivory Tower	10%		04%
Hard Copy		20%	16%
Microfiche		10%	08%
Electronic		40%	32%

NOTE: Column one percentages are 100% of subheading percentage in column two, while column two percentages are 100% of column three subheading. The percentages in column three are actual percentages of the total budget.

Figure 7A. Notional National Intelligence Resource Realignments

c. Establish a National Information Requirements Council. Identify an organization able to coordinate demands for information with global collection activities and impose the common sense guideline of exploiting open sources as "the source of first resort". This has the interesting ramification of also making much more of what we need to know obtainable through private sector capabilities rather than government capabilties.

d. Establish Open Source Focal Points Within United States and Other Countries. Within the United States, contract with two separate organizations: the first should serve as a complement to the Embassy and as a rapid-response local representative for the national intelligence council. It's role should be one of requirements management, oversight, and product packaging. The second organization should actually carry out all the research through sub-contracted collection and production, with value-added quality control. Similar arrangements can be made in other countries, perhaps by building on the established SVP network.

8. References

A resume and a list of selected personal publications are attached. The *Proceedings* of the First International Symposium on "National Security & National Competitiveness: Open Source Solutions", are the sole existing foundation for a national intelligence restructuring of this magnitude. A copy of both volumes is provided as part of this report, together with copies of more recent articles, speeches, and testimony bearing on this issue.

Other works of importance include: Jon Sigurdsom and Yael Tagerud (eds), *The Intelligent Corporation: The Privatization of Intelligence* (Taylor Graham, 1992); Alvin Toffler, *War and Anti-War: Survival at the Dawn of the 21st Century* (Little, Brown, forthcoming), see especially the chapters on knowledge warriors and the future of the spy. Winn Schwartau, *Information Warfare: How to Wage and Win War in Cyberspace* (Interpact, forthcoming); James Holden-Rhodes, *Sharing the Secrets: Open Source Intelligence and the War on Drugs* (Sandia National Laboratory, forthcoming)

9. Date of Information. 17 September 1993

APPENDIX D

CONCISE DIRECTORY OF SELECTED INTERNATIONAL OPEN SOURCES & SERVICES

DOI: 1 March 1996

Prepared by Robert D. Steele
Based on Research As Published in *OSS NOTICES* 1992-1996

ACCESS INNOVATIONS, INC.

Ms. Marjorie Hlava, President
Post Office Box 40130
Albuquerque, NM 87196
Voice: (505) 265-3591
Fax: (505) 256-1080

Ms. Hlava has been past president of the major information associations in the USA including the American Society for Information Science and the Association of Independent Information Producers.

BDM FEDERAL

Mr. Tom Price III
Principal Staff Member
1501 BDM Way
McLean, VA 22101-3204
Voice: (703) 848-5203
Fax: (703) 848-6683

The National Security & Technology Applications Division is under the leadership of LtGen C. Norman Wood, USAF (Ret), former Director of the Intelligence Community Staff, and specialized in OSINT support to U.S. intelligence.

BRITISH LIBRARY, THE

Mr. Mike Curston
Document Supply Centre
Boston Spa, Wetherby
West yorkshire LS23 7BQ
UNITED KINGDOM
Voice: (44 937) 546-333
Fax: (44 937) 546-061

Something like the U.S. Library of Congress, but better organized and focused on solid business practices. Known world-wide for its access to obscure sources and especially for its access to conference proceedings. Produces CD-ROMS, others aids.

BURWELL ENTERPRISES

Ms. Joanne Pauline
Marketing Director
3724 FM 1960W, Suite 214
Houston, TX 77068
Voice: (713) 486-3500 x 2353
Fax: (713) 920-7086

Ms. Helen Burwell is the publisher of the *Burwell Directory of International Information Brokers*, and recently added an index to this work which identifies brokers who speak a foreign language, and are familiar with in-country databases.

CIESIN (CONSORTIUM FOR INTERNATIONAL EARTH SCIENCE NETWORK)

Mr. Robert J. Coullahan

Director of Government & International Programs
1747 Pennsylvania Avenue, N.W.
Suite 200
Washington, D.C. 20006
Voice: (202) 775-6606
Fax: (202) 775-6622

This organization is a non-profit and one of the best sources of meta-data: data about environmental information, including imagery and seismic data, held by others around the world. Excellent advisors.

CISTI

The Canada Institute for Scientific and Technical Information, originally focused on meeting the needs of Canada, has expanded in recent years to offer its services to the North American customer base. Their online catalogue is available free at <http://www.cisti.nrc.ca/cisti/serlist.html>. For more information contact Document Delivery Services, CISTI, National Research Council, Ottawa, Ontario K1A OS2, Canada. Voice: (613) 993-9251, facsimile (613) 952-8243. Email: <cisti.docdel@nrc.ca>.

CLEARINGHOUSE FOR SUBJECT-ORIENTED INTERNET RESOURCES

University of Michigan

60 subject-matter guides including:

- Aerospace Engineering
- Archives on the Internet
- Government Sources of Business & Economic Information
- Neurosciences Internet Resource Guide
- U.S. technology Public Policy

Example of university resources being applied for the common good.

<gopher.lib.umich.edu>, look for "What's New and Featured resources", go to "Clearinghouse". Or anonymous ftp to <una.hh.lib.umich.edu path:/inetdirstaks>. If you have trouble, email <lou@umich.edu>.

Derwent World Patents Index

Available through DIALOG, Questel/Orbit, and STN. Communicate with Derwent Publications, Ltd., Derwent House, 14 Great Queen Street, London WC2B 5DF, United Kingdom. Voice: (44 171) 344-2800 or in the USA (703) 790-0400. Web: <http://193.128.218.44/products/>.

DIALOG (Knight-Ridder)

Mr. David Brown, Team Leader
Government Team, Suite 500
1901 North Moore Street
Arlington, VA 22209
Voice: (703) 908-2383
Fax: (703) 524-1680

One of the two leading commercial online services--it is very important to understand that both DIALOG and LEXIS-NEXIS are required to "hit" 2/5ths of the available online information, and that the other 3/5ths require additional research.

Directory of Publications and Broadcast Media

Available from Gale Research for $295. ISBN 0-8103-7188X. Formerly titled the *Directory of Directories*, this is a recommended starting point for virtually any search.

Disclosure, Inc.

Disclosure, Inc., 5161 River Road, Building 60, Bethesda, MD 20816. Web: <http://www.disclosure.com/>.

E2G (UK)

Mr. William Owen, Managing Director
2nd Floor, 1 Northumberland Avenue
Trafalgar Square
London WC2 N5BW ENGLAND
Voice: (44 171) 487-3626
Fax: (44 171) 487-3817

Former Special Air Service and other British special forces personnel are available through this organization to conduct route reconnaissance, develop military maps, and provide other pre-landing support services.

EASTVIEW PUBLICATIONS

Manager
Gray Literature Acquisitions
3020 Harbor Lane N
Minneanapolis, MN 55447
Voice: (612) 500-0961
Fax: (612) 559-2931

This organization is one of the best in the world at acquiring "grey literature", with a strong specialization in Russian and East European literature. They are also the foremost source of Third World maps, including tactical maps, created by USSR.

Encyclopedia of Associations

Available from Gale Research for $250. ISBN 0-8103-7421-8.

FIND IT FAST: HOW TO UNCOVER EXPERT INFORMATION ON ANY SUBJECT

Robert Beckman, Author
Harper Collins, Publisher
$13, Cost
(800) 427-7372

As described--an essential handbook for the analyst interested in exploiting the open source world.

FIND/SVP

Mr. Joseph Cositore, Vice President
625 Avenue of the Americas
New York City, NY 10011-2002
Voice: (212) 645-4500
Fax: (212) 645-7681

FIND/SVP ("SVP" in French stands for "if you please") specializes in obtaining any article, any document, through a world-wide network of franchises. It does almost no analysis, just acquisition.

FULD & COMPANY

Mr. Leonard Fuld, President
80 Trowbridge Street
Cambridge, MA 02138
Voice: (617) 492-5900
Fax: (617) 492-7108

Publisher or *The New Competitor Intelligence*, a handbook for business intelligence specialists. Includes resource listing--strongest of Europe.

GaleNet

GaleNet can be used by anyone with an Internet connection, either dial-up or direct, and a graphical World-Wide-Web browser. The Web site offers a demonstration area. OSS tested their site by accessing the *Encyclopedia of Associations*, using the word "information", and found 138 associations that have "information" in the keyword search field. To arrange for a demonstration of GaleNet at your site, or for more information, please call the National Field Sales Manager, Mr. Tim Brandner, at (510) 671-5379, or send email to <Tim brandner@gale.com>.

Genuine Article

A service of the Institute of Scientific Information. Contact Mr. Frank Spiecker, 3501 Market Street, Philadelphia, PA 19104. Voice: (215) 386-0100 extension 1374; Facsimile: (215) 386) 6362. Web: <http://www.isinet.com/>.

GUIDE TO NETWORK RESOURCE TOOLS

by European Academic & Research Network
Free of charge online
Go to <listserv@earncc.bitnet>
Send command <GET NETTOOLS PS> (for postcript) or
Send command <GET NETTOOLS MEMO> (for plaintext)
Covers Archie, Astra, Bitftp, Gopher, Listserv, Netnews, Netserv, Trickle, WAIS, Whois, and World-Wide-Web

As described.

INDIVIDUAL, INC.

Director, New Business
8 New England Executive Park West
Burlington, MA 01803
Voice: (617) 273-6000
Fax: (617) 273-6060

This is one of the finest "current awareness" services, providing a one page listing of "hits" on your profile by fax or email, with full-text available immediately through automated order.

Information Broker's Handbook

By Sue Rugge and Alfred Glossbrenner. Published by Windcrest/McGraw-Hill, 1992. ISBN 0-8306-3797-4. $30.95, order through local bookstores.

INFOSOUTH

University of Miami
(800) 752-9567

Translations of Latin American press. biographies on Latin American leaders.

INSIDE INFORMATION: PROFILES OF ASSOCIATION LIBRARIES AND INFORMATION CENTERS

Special Libraries Association
Mr. Kevin Heffner, Director
Fund Development
1700 Eighteenth Street, N.W.
Washington, D.C. 20009
Voice: (202) 234-4700 ext. 631
Fax: (202) 265-9317

This is the international organization that serves over 15,000 librarians in charge of small specialized libraries for associations, corporations, or other special interests. This is an essential networking vehicle for reaching limited edition publications, especially in economic and financial arena.

International Thomson Publishing

Their Web site is located at <http://www.thompson.com>. To receive a catalog you can write to them at 7625 Empire Drive, Florence, Kentucky 41042, call voice (800) 865-5840, facsimile (606) 647-5013, or send email to <americas-info@list.thomson.com>

JANE'S INFORMATION GROUP

Mr. Robert Loughman
Sales Consultant
1340 Braddock Place, Suite 300
Alexandria, VA 22314
Voice: (703)683-3700x202
Fax: (703) 836-0297

The Jane's periodicals, database, and *SENTINEL* Country Series are "best in class" for military information. Jane's is also available online. It is important to know that Jane's only publishes 20% of what it knows, ask for unpublished info.

KROLL ASSOCIATES

Mr. Thomas Fedorek, Managing Director
900 Third Avenue
New York, NY 10022
Voice: (212) 593-1000
Fax: (212) 593-2631

This is by all press and other accounts the world's best investigative firm, able to obtain scientific & technical information as well as other nominally sensitive information, using legal & ethical means.

LEXIS-NEXIS

Mr. Jeff Krattenmaker
Government Information Services
9393 Springboro Pike, P.O. Box 933
Dayton, OH 45401-0933
Voice: (513) 865-1877
Fax: (513) 865-7902

Together with DIALOG, one of the top two commercial online services, but perhaps best suited to be the "first stop". followed by DIALOG and other region-specific online services. "Government-friendly" and responsive.

Mercyhurst College

Mr. Robert Heibel, Program Director, Research/Intelligence Analyst Program. Mercyhurst College, Department of History, Erie, Pennsylvania 16546. Voice: (814) 824-2117, fax: (814) 824-2219.

MONTEREY INSTITUTE OF INTERNATIONAL STUDIES

Dr. Christopher Fitz
Senior Manager
PNS, 425 Van Buren Street
Monterey, CA 93940
Voice: (408) 647-4193
Fax: (408) 647-3519

Uses graduate students fluent in Arabic, Russian, Vietnamese, and Korean, and other languages, to monitor media and maintain world's best unclassified database on proliferation--used by CIA's NPC.

NERAC

Manager, New Business
One Technology Drive
Tolland, CT 06084-3900
Voice: (203) 872-7000
Fax: (203) 875-1749

Combines DIALOG and university experts to offer an annual "fixed price" research service that many businesses find to be responsive and cost-effective.

netguide

"TV Guide" of cyberspace
Covers 60,000 bulletin boards
9,000 networks, 500 libraries,
all commercial online services
384 pages, $19.00, (800) 345-8112

As described--there are increasing numbers of such guides, most at higher prices. This is a good starting point.

***NEWSEDGE* FROM DESKTOP DATA**

Ms. Emily Elliott, Assistant Marketing Manager
Financial Markets
1601 Trapelo Road
Waltham, MA 02154
Voice: (617) 672-2425
Fax: (617) 890-1565

This unique service combines the normal current awareness service with the ability to deliver data directly into existing local area networks & database structures.

OXFORD ANALYTICA

Mr. Robin Porteus
Director of Client Services
5 Alfred Street
Oxford OX1 4EH
UNITED KINGDOM
Voice: (44 1865) 261-600
Fax: (44 1865) 242-018

Founded by Mr. David Young, who served on the National Security Council with Dr. Henry Kissinger, this is the best international window into political and economic reporting. Combines the Dons of Oxford and 1000 experts worldwide, with a 24-hour media monitoring service.

PARVUS-JERICHO

Mr. Gerard Burke, Chairman
8403 Colesville Road
Suite 610
Silver Spring, MD 20910
Voice: (301) 589-4949
Fax: (301) 589-0007

After Kroll Associates, one of the best international investigative organizations. Mr. Burke served previously as the Executive Director of the President's Foreign Intelligence Advisory Board, and can support community needs.

Questel/Orbit

Communicate with them at Questel/Orbit, Inc., France Telecom Group, 8000 Westpark Drive, McLean, VA 22102, voice (703) 442-0900, or facsimile (703) 898-4632.

RAPPORT RESEARCH & ANALYSIS (UK)

Mr. Charles Pettifer, Director
Mr. Kevin Dodd, Director
11 Berkeley Street
Mayfair, London W1X 6BU ENGLAND
Voice: (44 171) 355-5020
Fax: (44 171) 355-5021

This organization can provide trained debriefers fluent in any language to any place in the world. Especially good at canvassing refugee and emigre communities for raw intelligence.

RESEARCHBASE

Mr. Frank J. Vega, President
Post Office Box 187
Arlington, VA 22210
Voice: (703) 271-5988
Fax: (703) 271-5989

This very low-cost ($500) database is an essential means of saving money by avoiding redundant research in all major international relations areas. Tap into existing research for starters!

Research Centers Directory

Sometimes titled *Research Centers and Services Directory*. Available from Gale Research for $400 (two volumes). ISBN 0-8103-7353X.

Rice University

Call (313) 764-9366 to obtain information on gaining access to the Economic Bulletin Board Service (BBS).

RISA SACKS ASSOCIATES

Ms. Risa Sacks, President
3838 14th Avenue
Oakland, CA 94602
Voice: (510) 530-6154
Fax: (510) 531-9086

Telephone surveys and telephone "discovery" of key elements of information is an art, and Ms. Risa Sacks is acknowledged by her peers as one of the best in the USA.

SCIENCE CITATION INDEX, SOCIAL SCIENCE CITATION INDEX

Institute for Scientific Information

Frank Spiecker
3501 Market St.
Philadelphia, PA 19104
Voice: (215) 386-0100 ext.1374
Fax: (215) 386-6362

This organization combines a citation database that will identify the latest articles based on known earlier publications, and also identify emerging technologies as well as key experts.

Secrets of the Super Searchers

By Reva Basch, 1993. Order directly from Eight Bit Books, 462 Danbury Road, Wilton, CT 06897-2126. ISBN 0-910965-12-9. $39.95 plus shipping & handling.

SIS INTERNATIONAL RESEARCH

Ms. Ruth Stanat, President
490 South Main Street
New City, NY 10956
Voice: (914) 639-1934
Fax: (914) 639-6936

Complements Fuld & Company with special strengths in Latin America and Asia; primarily a business/marketing research organization.

SPOT IMAGE CORPORATION

Mr. Clark Nelson, Director of Communications
1897 Preston White Drive
Reston, VA 22091
Voice: (703) 715-3100
Fax: (703) 648-1813

They have, in hand, 10 meter resolution panchromatic and multispectral imagery for almost the entire world, and can produce both combat charts and simulations quickly.

STN International

STN Service Center, c/o Chemical Abstracts Service, 2540 Olentangy River Road, Columbus, OH 43210. Voice: (800) 848-6533, facsimile (614) 447-3798. Email: <help@cas.org>.

The Reference Press, Inc.

Among its offerings are a variety of directories and guides to international business sources and information for Latin America, Canada, Europe, Asia Pacific, and Russia. For a catalog call (512) 454-7778 or fax (512) 454-9401.

WORLDWIDE GOVERNMENT DIRECTORIES

Mr. Jonathan Hixon, Publisher
7979 Old Georgetown Road, #900
Bethesda, MD 20814
Voice: (301) 718-8770

Mr. Keith Hall invented the term "ASK-INT". This is the directory. They also publish government and military

Fax: (301) 718-8494

biographies for leaders worldwide.

UNCOVER REVEAL

Uncover Company
3801 East Florida
Suite 200
Denver, CO 80210
Voice: (303) 758-3030
Email: <mwhitaker@carl.org>

Building on the University of Colorado's existing infrastructure, they will deliver for a nominal cost to your email or fax the tables of contents of all journals you wish, as they are published--then you can order articles from any source.

UNITED PRESS INTERNATIONAL

Ms. Alison Myers
Director of Business Development
UPI Photo Network
Voice: (202) 898-8248
Fax: (202) 371-8247

A picture can be worth a thousand words. Analysts interested in using visual images to improve the intelligence consumer's absorption of the intelligence product's content can call on this resource.

University of Michigan

Send electronic mail to <lou@umich.edu> to obtain information on gaining access to the electronic clearinghouse.

APPENDIX E-1

Internet: Self-Guided Tour

by Dr. Ross Stapleton-Grey <director@embassy.org>

1. Philosophy
2. Strategies
3. Useful Tools
4. Starting Points
5. Print and Other Resources
6. USENET Illustration

Philosophy

The Internet is a steadily changing thing. What's there today will almost certainly be different tomorrow, either for the better, or for the worse! This poses a challenge when useful resources disappear, whether because they've been abandoned, or simply moved with no apparent forwarding address. On the other hand, hosts of new resources are being created every day... faster than they're being cataloged. The Internet has been described as "a wonderfully rich library, but all the books are lying in heaps on the floor."

The last few years have seen a number of wonderful navigational aids created, including powerful search engines, and comprehensive catalog sites for Web page creators to register their resources. But there will always be a place for serendipity, and certainly it helps to have a network of contacts and colleagues to pass along leads.

Strategies

The best strategy in looking for information via the Internet is to cast a broad net: Web sites will lead to others, or cite newsgroups or mailing lists, or vice versa, and human contacts made through the Internet can pass along useful nuggets.

All of the major Web browsers support "bookmarking," i.e., saving pointers to particularly useful or interesting destinations once you've found them (placing them on your "hotlist"). A helpful strategy is to bookmark all of the initial tools--query sites, or especially rich indexes--you might need, along with other sites you'll need to check regularly.

Useful Tools

The following are useful tools for the Internet (and especially, World Wide Web)

navigator. They can also be thought of as starting points: the skilled Internet navigator will make use of any number of search and catalog sites, to access familiar resources, or to launch off into undiscovered territory with a few search keywords.

Alta Vista - http://altavista.digital.com

One of the newest search engines, established by Digital Equipment Corporation (DEC), a major mid-range system manufacturer, as a technology demonstrator and a means to attract an audience. The service claims to index 8 billion words from some 16 million Web pages, and to continuously update its contents, retiring old materials no longer found, and adding new pages when encountered (some indexes don't--or can't--retire old pages, and may return links that lead to nowhere).

Alta Vista is the most impressive raw search engine for the World Wide Web thus far created. In addition to simple queries, one can structure complex searches, with weighted terms, and all of the usual Boolean search qualifiers. But the search tool has also been designed to meet the specific needs of Web navigators: one can search by date of the document (critical when what's needed is current information, and not some aging Web page with last year's news), and for URLs (Web page "universal resource locators," the "http:www.etc..."). The latter allows for neat tricks: check Alta Vista's help menus for directions on how to search for all of the Web pages that reference a certain other page, or how to find all of the pages mentioning certain terms, but which are not at some given address.

In addition to searching for Web pages, Alta Vista can search the most recent traffic in many of the USENET news groups.

Yahoo - http://www.yahoo.com

The most significant index in the Web's first major growth spurt, and the first comprehensive index of sites. Having one's Web site registered in Yahoo was (and is) a necessity. Yahoo involves human cataloging (submitters request where they would like to be filed, but Yahoo staff implement all linking), as opposed to the full-text indexers like Alta Vista. Where Alta Vista is an excellent tool to pull in anything and everything matching a given set of keywords, Yahoo's strength is in its organization. It would be extremely difficult to compile an exhaustive list of organizations in a given field by sifting through the mixed page of Web pages returned by Alta Vista; Yahoo will have a well-ordered index of companies divided and subdivided up according to a logical hierarchical structure. On the other hand, while Alta Vista vacuums up and indexes anything it can find on the Web, Yahoo is only as thorough as submitters and catalogers make it.

Yahoo also has an arrangement with Reuters to provide current newswire material through its site. The "Xtra" pages provide breaking items (a dozen or so per category) in Politics, News and World News, Business, Internet and Computers, and a half dozen other

areas.
http://webcrawler.com

An early full-text indexing tool, bought by America OnLine for more than a million dollars. It's included here largely for historical reasons, as other tools like Alta Vista seem to be eclipsing it. Webcrawler also has the annoying feature that it retains everything ever put in its index: pointers to Web pages that have been deleted long ago will still be found, and will give the user the famous "404 - URL Not Found" error when the link is followed.

A number of other services provide searching of extensive amounts of the World Wide Web, including OpenText (http://www.opentext.com) and Infoseek (http://www.infoseek.com).

Starting Points

All of the search tools mentioned previously are excellent starting points. In addition to those, the following sites are rich indexes to their various areas:

NewsPage - http://www.newspage.com

NewsPage is a valuable site for industry information, including the telecommunications, energy, pharmaceutical and other industries. The site pools press releases and other news from a variety of other online services, and organizes them by category. While the site bases some of its revenues on advertising, it also charges premium subscription fees for some of its articles, and for use of a search facility.

Online Newspapers - various

Numerous "physical" news papers such as the Detroit News, San Francisco Chronicle, and New York Times have created Web versions to allow readers greater access to their stories, and to complement the print versions.

The Detroit News Web site (which was launched, coincidentally, as the print paper was in the middle of a union strike, and which has provided news on the strike as an editorial soapbox for the paper) is a good example of a Web site's use of a structured presentation: each day's format is identical, even if the content changes, providing a familiar layout. The Detroit News Website is at http://detnews.com.

Other good jumping off points to online newspapers:

Yahoo's newspaper index:

http://www.yahoo.com/Business_and_Economy/Companies/Media/Newspapers/

The Newspaper Association of America homepage : http://www.infi.net/naa/hot.html

The White House - http://www.whitehouse.gov

In addition to holding information on the White House, the Executive Office of the President, and the texts of presidential and vice presidential speeches, the White House Web site is the "site of sites" for the Federal Executive Branch. White House staff have taken considerable care to encourage Federal agencies to provide Web addresses, and the site indexes all of the major cabinet offices and a great many of the other agencies, bureaus and programs.

The WELL's War Conference, IW sites -
http://www.well.com/conf/war/iwsites.html

Participants in the War conference on the WELL (a large online conferencing system based in Northern California but with users worldwide) have compiled an extensive reference of Web sites of interest to the "Information Warrior" (largely of defense, economic security and
intelligence related sites). Some of the sites included on the list (a small sampling):

The White House's Information Infrastructure Task Force - http://www.iitf.doc.gov
Office of the Secretary of Defense - http://enterprise.osd.mil
US Air Force - http://www.afin.af.mil
Air Force 38th E&I Wing - http://www.eiw38.af.mil/cshome.html
Central Intelligence Agency - http://www.odci.gov/cia
Intelligence Community - http://www.odci.gov/ic

Electronic Embassy - http://www.embassy.org

The Electronic Embassy Web site is an index to information, including Web homepages where available, from the foreign embassy community in Washington D.C.

All of the above ought to be considered merely starting points, and most lead quickly to many other resources. The White House site is an exhaustive list of Federal agencies, while the Electronic Embassy is a quick shortcut to find the State Department, foreign affairs committees of the Congress, or the United Nations.

The more the Internet begins to parallel the "real world," that is, as having a Web site becomes the rule for companies, and not just the innovative exception, traditional clearinghouses will have a role to play. The Software Publishers Association (http://www.spa.org), for example, has long been an advocacy organization for the software industry, with a large number of the most significant software producers as members. The SPA Web site, extending its member services onto the Internet, provides a lengthy index to all of its members, with pointers to their own Web sites.

There are excellent "theme" pages created by individuals, compiling exhaustive lists of known resources on the Web under a given topic area. These might range from Feminist Activist resources (Sarah Stapleton-Gray's page at IGC - http://www.igc.org/women/feminist.html) to anything and everything related to telecommunications organizations, technologies and policy (Jeff MacKie-Mason's page at the University of Michigan, http://www.spp.umich.edu/telecom-info.html). While one could try to compile a list of these lists (and to some extent such a thing has been done with Yahoo). spending even a small amount of time "surfing" the Web is guaranteed to turn up such useful references, which can then be bookmarked.

Print and Other Resources

The nature of the Internet is such that virtually any print resource, and certainly any that attempts to document an exhaustive list of anything, be it USENET newsgroups or "the best Web sites for...," becomes obsolete in a manner of months. That said, there are some fairly useful books on various aspects of the Internet and the World Wide Web, which can give a good feel for the tools and the Internet's content, while recognizing that any given list of Web sites will have changed even as the book went to the printers.

The O'Reilly and Associates series of books are essential reading for the nuts and bolts of how the Internet works. *The Whole Internet User's Guide and Catalog* is a basic primer, with extensive (but, of course, fast-aging) lists of useful sites, mailing lists and newsgroups. *Managing Internet Services* provides extensive information on the technical details of Gopher, Majordomo (mailing list software) and the World Wide Web--not for the novice but providing for a complete understanding of how all of these features actually work.

HTML Sourcebook, by Ian S. Graham (John Wiley & Sons, publisher) is a good overview of how to create pages for the World Wide Web, again providing good insight into how the Internet supports the Web, and how Web sites work. The book provides walk-throughs of several actual sites, dissecting them to show how the Web can be used to deliver information, query users using forms, etc.

Members of the Internet Society receive its "On The Internet," a bi-monthly magazine on Internet issues and features. Individual membership in the Society is $35 per year. ISOC may be reached at:

The Internet Society
12020 Sunrise Valley Drive, Suite 210
Reston VA 22091
(703) 648-9888

ISOC also has a Web site:
http://www.isoc.org as does its
DC area chapter:
http://www.dcisoc.org

USENET Illustration

NOTE: For each of these, the first column is the message number. the second column shows the number of replies, if any, followed by the message title and the poster's userid.

APPENDIX E-2

Intelligence-Oriented List of Useful Internet Sites

From the Staff of OSS, Inc. <oss@oss.net>

NOTE: The material which follows focuses primarily on World-Wide Web (www) sites because that is the overwhelmingly most productive environment. Gopher sites (menus providing access to text) and File Transfer Protocol (FTP) sites are still available but declining so quickly as to hardly be worth citing. Also, it is important to do your own searches for sites and to regularly update your lists. The Net is growing geometrically, and sites emerge (or die) every day. The sites listed below are simply illustrative, and by no means comprehensive. Besides regular searches of the www, analysts should subscribe to ListServs in their areas of interest--these deliver documents directly to an email address, and also allow for analysts to contribute commentary to the list for rebroadcast to others.

Top Guns

http://www.oss.net/oss/

The home page of OPEN SOURCE SOLUTIONS, Inc., a non-profit educational corporation that serves as an international clearinghouse for information about open sources, systems, and services, this site provides past issues of *OSS NOTICES* for free, and is soon to offer, also for free, digital copies of the two volume *Proceedings* from each of the annual conferences on open sources which have taken place since 1992. This site offers direct links to a number of other open source vendors and pertinent sites for open source intelligence.

http://www.tiac.net/users/jardines/434mid.html

These heavy-duty reservists, the 434th Military Intelligence Detachment (Strategic), created the first-ever *Open Source Intelligence Resources for the Military Intelligence Officer*, and kicked off an Army-wide effort that is now leading joint concepts and doctrine on the integration of open source intelligence into the all-source collection and production process.

http://www.awpi.com:80/IntelWeb/

The home page of *Intelligence Watch Report*, a daily electronic clipping service for intelligence-related news, and the only service of its kind focused strictly on national intelligence. Benefits from correspondents in Europe, Russia, and Asia.

http://www.fedworld.gov/

FedWorld, the central point of access to the entire U.S. government, very ably

developed and maintained by the National Technical Information Service. a self-sustaining activity of the Department of Commerce.

APPENDIX E-3

Intelligence (Related) Sites from *PC Magazine*'s Top 100 Web Sites

Selected by the Staff of OSS, Inc. <oss@oss.net>

NOTE: The sites listed below are drawn from "Web Sites 100: PC Labs Rates the Top 100", in *PC Magazine* Volume 15, Number 3 (6 February 1996). The quickest way to explore all of these sites is through the online version of the story, available at <http://wwkw.pcmag.com>, where the list will also be constantly updated.

Computer Resources

BrowserWatch http://www.ski.mskcc.org/browserwatch/

The best place to follow emerging Internet browser tools.

O'Reilly and Associates http://www.ora.com

Publishers of such respected books as *Computer Crime: A CrimeFighter's Handbook*, this organization is a good place to identify educational materials for all aspects of Internet research.

News & Sports

CNN Interactive http://www.cnn.com

Includes a video vault as well as a keyword search tool for past CNN stories. Could be the ideal source for downloading film and sound "snapshots" for a multi-media briefing.

Electronic Telegraph http://www.telegraph.co.uk/

The respected London newspaper.

Reuters NewMedia http://www.yahoo.com/headlines/current/news

Rapid bare-bones reporting, strictly text-based.

Time Magazine http://www.pathfinder.com/time

Everything you would expect, including *Time Daily*, late-breaking news.

USA Today http://www.usatoday.com

Retains its graphical excellence. Includes cyber-listings.

Government & Politics

FedWorld Information Network http://www.fedworld.gov/

Access to over 130 government bulletin boards as well as many government Web and gopher sites.

GPO Gate http://ssdc.ucsd.edu/gpo

Includes full-text of major GPO publications such as the *Federal Register*, *Congressional Record*, Senate and House calendars, and the United States Code.

The Library of Congress http://www.loc.gov

Includes THOMAS, a Web version of the *Congressional Record*, and other Capitol Hill publications. Often mis-represented as providing access to 70 million actual documents, what it really provides is access to the listing of such documents. It does have some full text material.

The United Nations http://www.un.org

Marginal in terms of substance, but some conference updates, news releases, and Security Council information.

Reference

Britannica On-Line http://www.eb.com

Costs money ($25 registration, $150 per year). Includes same content as bound edition, articles not yet in print, *Britannica Book of the Year*, and *Webster's Dictionary*.

CityNet http://www.city.net

While not a comprehensive guide, it does cover sites from Scotland to Africa, and is an interesting illustration of the kind of beach surveys and city maps that might one day be available to arriving military forces accessing the Internet from their landing platforms.

Science, Technology, & Medicine http://www.asap.unimelb.edu.au/hstm/hstm_ove.htm

Historical in nature, part of the Virtual Library, includes biographical information,

documents on every area of technology, a directory of scientific institutions, and electronic journals.

APPENDIX E-4

HOW TO FIND AN INTERESTING MAILINGLIST

Arno Wouters - Arno.Wouters@phil.ruu.nl
(with minor modifications by OSS, Inc. staff)

Last update: 5 February 1994

This document is available by email from "listserv@vm1.nodak.edu" with "GET NEW-LIST WOUTERS" or by anonymous ftp from "vm1.nodak.edu" as "new-list.wouters" in the directory "new-list".

(In compiling this information I have made ample use of Marty Hoag's "Some lists of list" (as of 05/01/92) which is retrievable from NEW- LIST as "LISTSOF LISTS")

TABLE OF CONTENTS

GENERAL INFORMATION ABOUT MAILINGLISTS

The "Directory of Scholarly Electronic Conferences" (ACADLIST)
NEW-LIST
LIST SEARCHES ON THE INTERNET

GENERAL INFORMATION ABOUT MAILINGLISTS

A mailing list is a computer program that distributes messages among a list of subscribers. This program has an email-address (listname@domain). Mail sent to this address is distributed automatically to all the subscribers.

There are two types of mailing lists: manually maintained lists and automated lists.

(1) In its manual form the list of subscribers is maintained by a person, the list administrator. To subscribe to such a list one should ask the list administrator to add you to the list. Typically the administrator can be reached at listname-request@domain.

(2) An automated list is maintained by a program (a so-called mailserver). To (un)subscribe to an automated list one should send a message to the mailserver. Usually.

this is the command "SUB listname Yourfirstname Yourlastname" to subscribe and "SIGNOFF listname" to sign off (substitute the appropriate names and leave off the quotes!).

A mailserver is a program that interprets the lines in a message as a series of commands to act on, for example to mail a file or to add a person to a mailing list. To learn how to handle a mailserver one should send a one line message containing the command "help" (no quotes!) to the mailserver's address. (In some rare cases, the mailserver needs an empty message with "help" in the subject).

LISTSERV is the name of the single most important mailserver on Bitnet. It provides three kinds of services: (1) mailing list management, (2) file archives, and (3) address registration. A userguide is available from LISTSERV@EARNCC.BITNET by sending it the command GET LSVGUIDE MEMO. The command HELP can be sent to any Listserv. It will give you a short list of commands. "INFO REFCARD" returns a longer list, "INFO GEN" a manual. Typically, if a list's address is LIST@NODE.BITNET the list is maintained by LISTSERV@NODE.BITNET. Alternatively, if LISTSERV@NODE.BITNET maintains a list named LIST the list's address is LIST@NODE.BITNET.

There are also Unix versions of Listserv that work on the Internet. Don't expect these versions to function exactly like the traditional Listserv.

IMPORTANT: One should carefully distinguish between the address of the list and the address of the administrator/mailserver. Never send requests/commands for (un)subscription to the list! Such a message would bother all the participants, but it would not help you to get on/off the list. Note, that the list administrator is often just that: one of the computer people who maintains the list, but is not himself a subscriber. Alternatively, a mailserver will only react to mail that is addressed to the mailserver's address, not to the address of the lists it maintains.

Type of list	Address of list	Requests/commands
Manually	listname@domain	listname-request@domain
LISTSERVed	listname@node.BITNET	LISTSERV@node.BITNET

TWO NOTES ON ADDRESSES

Internet addresses have the format user@domain (for example John.Doe@phil.ruu.nl). Bitnet uses the format user@bitnetnode (for example JDOE@HNYKUN51). To send mail from Internet to Bitnet append ".BITNET" to the Bitnet address (e.g. JDOE@HNYKUN51.BITNET). To send mail from BITNET to Internet one could use the Internet address without any changes.

Janet users in the United Kingdom should reverse the order of the Internet domainnames and Internet users outside the UK should reverse the order of Janet domainnames.

There are several lists of lists available. The main ones are:

-- the Listserv "list of lists" on Bitnet;
-- the Internet "interest-groups" list;
-- two lists of Usenet newsgroups;
-- the Usenet list of "Publicly Accessible Mailing Lists" on Internet and UUCP networks;
-- a combined list of Bitnet and Internet lists from Dartmouth (SIGLIST):
-- the "Directory of Scholarly Electronic Conferences" (ACADLIST), an annotated list of mailing lists, newsgroups, newsletters, electronic journals etc. that are of interest to academics;

Another important sources is:

-- NEW-LIST, a Listserved mailing list and archive for announcements of new lists. In addition, the NEW-LIST archive contains copies of both the Listserv and the "interest-groups" lists of lists in a searchable format.

NOTE: The WAIS based "lists" database on CIC-net has been dissolved.

TOOLS and METHODS

Basically, there are two methods to access these sources:

(1) on line searches

(2) retrieve a list and search through it at home (electronically or after printing).

As most lists are long, the first method is often the preferred one.

Internet tools for on line retrieval: gopher, WAIS, telnet (one tool would suffice, gopher is the preferred one for lists).

Listserv databases can be searched interactively from VAX/VMS and from VM/SP CMS systems. Other users should submit batch jobs by email. Send an "INFO DATABASE" to an appropriate Listserv for more information.

Tools for retrieving files: anonymous ftp (Internet only) and email. Make sure you have enough disk space available, since most lists are VERY long.

Tools for searching the retrieved files include your favorite word processor, GREP commands, hypercard etc.

The LISTSERV "List of lists"

The Listserv list of lists contains one line descriptions of Listserved lists on Bitnet. Most (but not all) Listservs will get you a copy after submitting the command "LIST GLOBAL". Most servers would also allow for the command "LIST GLOBAL /string" (e.g. "LIST GLOBAL /philos") to get those lists which have "string" in their description.

The SRI NISC "interest-groups" list of lists

This is a list with descriptions of special interest group mailing lists available on the Internet, compiled by Steven Bjork. New versions of this list are typically issued on a quarterly basis.

The file "interest-groups" (over 1.2 MB!) is available: by anonymous ftp from sri.com in the directory "netinfo", or by email from mail-server@sri.com ("send interest-groups").

A hardcopy, indexed version is available from Prentice Hall under the title *Internet: Mailing Lists* (ISBN 0-13-327941-3).

The USENET lists of newsgroups and mailing lists

David Lawrence maintains two lists of newsgroups on Usenet. The "List of Active Newsgroups" lists the regular Usenet newsgroups. The Usenet software also allows the transport of hierarchies of newsgroups not part of the "traditional" Usenet (bionet, alt-groups, bit.listserv etc.). These groups are listed in the list of "Alternative Newsgroup Hierarchies". Both lists contain one line descriptions.

Stephanie da Silva maintains the list of "Publicly Accessible Mailing Lists". This is a list of mailing lists available primarily through the Internet and the UUCP network. The list includes short descriptions of the purpose of the lists.

These lists are distributed via the Usenet newsgroups news.lists and news.answers (monthly updates). News.answers is archived at many sites. The files are named "active-newsgroups", "alt-hierarchies" and "mailing-lists". They can also be obtained from the MIT Usenet archive: by anonymous ftp from rtfm.mit.edu in "/pub/usenet/news.answers" or via email from "mail-server@rtfm.mit.edu". The appropriate commands are:

send usenet/news.answers/active-newsgroups/*

send usenet/news.answers/alt-hierarchies/*

send usenet/news.answers/mail/mailing-lists/*

The Dartmouth SIGLIST

David Avery from Dartmouth maintains a combined edited list (over 500 KB!) of Listserved and manually maintained lists on both Bitnet and Internet. The list includes short descriptions of the purpose of the lists and is sorted by category (computing, science, humanities etc.). It is updated monthly. Dartmouth provides several versions of the list. They also provide several applications (MacIntosh Hypercard, MSDOS, VM/CMS, VAX/VMS and Unix) that present the list in a nice format and facilitate searches.

SIGLIST is available:

-- by anonymous ftp from DARTCMS1.DARTMOUTH.EDU in directory SIGLISTS.

-- by email from LISTSERV@DARTCMS1.BITNET ("INDEX SIGLISTS" for a list of files and "GET READ ME" for more information)

The "Directory of Scholarly Electronic Conferences" (ACADLIST)

From the README file: "This directory contains descriptions of electronic conferences (e-conferences) on topics of interest to scholars. E-conference is the umbrella term that includes discussion lists, interest groups, e-journals, e-newsletters, Usenet newsgroups, forums, etc. We have used our own judgment in deciding what is of scholarly interest, and accept any advice or argument about our decisions."

ACADLIST (from Kent State University) is an annotated list. The entries are placed into categories according to the academic subject area of the e-conference. ACADLIST consists of 8 separate text files. Please note that the first four files contain several subject areas arranged in alphabetical order. FILE1 is titled: "Anthropology-Education", this means that it contains all the subject areas that fall alphabetically between A and E! The list is also available as a two file HYPERCARD stack and as a one file MS WORD document (MAC version!).

ACADLIST is available:

-- by anonymous ftp from KSUVXA.KENT.EDU in the directory "library" (get "acadlist.readme" for more information).

-- by email from LISTSERV@KENTVM.BITNET ("GET ACADLIST README"

for more information).

NEW-LIST

The NEW-LIST mailing list at LISTSERV@NDSUVM1.BITNET provides announcements of new mailing lists. To subscribe send the command "SUB NEW-LIST Yourfirstname Yourlastname" to the LISTSERV. The mailing list is gatewayed to Usenet as the newsgroup "bit.listserv.new-list". The NEW-LIST archive is the principal source for list searches. It contains three databases in a searchable format:

-- lists: the LISTSERV list of lists
-- intgroup: the Internet "interest-groups" list
-- new-list: the archived contributions to the NEW-LIST mailing list.

From Marty Hoag's "Some lists of lists":

For example, to search of both these databases for lists on "bicycles" you would send the statements

```
 //DBlook  JOB  Echo=No
Database Search DD=Rules
//Rules DD *
Select bicycle in lists
index
Select bicycle in intgroup
index
Select bicycle in new-list
index
/*
```

in the text/body of the mail to LISTSERV@VM1.NoDak.EDU or on BITNET just LISTSERV@NDSUVM1 . These statements would search the global LISTSERV list of lists ("in lists"), and the local copy of the SRI-NIC Interest Groups ("in intgroup"), and the archives of the "new-list" list ("in new-list")."

To get more information subsequently submit the following job (substitute "list-number(s)" by the numbers of the lists of interest found in the first job, separated by spaces):

```
// JOB Echo=No
Database Search DD=Rules
//Rules DD *
Select bicycle in lists
```

index
print list-number(s)
Select bicycle in intgroup
index
print list-number(s)
Select bicycle in new-list
index
print list-number(s)
/*

Send LISTSERV the command INFO DATABASE for more information.

LIST SEARCHES ON THE INTERNET

Many sites provide a searchable version of one or more lists of lists via gopher. To find them, connect via gopher to a Veronica-server (usually, you'll get there by choosing something like "Other gopher and information servers" in your main menu) and search for "-t7 list lists" "-t7 mailing lists" and/or "-t7 interest groups". The "-t7" addition assures that you'll get searchable versions only. A search for "list lists" will give you about 20 links, "interest groups" about 30, "mailing lists" more then 100, and "lists" more then 4,000. However, this method has several drawbacks. The most important one is that you can never be sure that the lists are regularly updated. There are sites that provide a version of February 1992! Another is that many of those links point to the ghosts of once existing databases (e.g. to lists.src or mailing-lists.src). The Lund University Library Services (Sweden) provides a searchable WAIS-based version of ACADLIST ("academic email conf.src"). There are several ways to access this database:

-- By means of your own WAIS client
-- There are more then 60 gophers linked to this database (use Veronica to find one).
-- Several gopher sites provide a general gateway to WAIS (e.g. the gopherhome in Minnesota).
-- Telnet to one of the following servers: quake.think.com (login: wais). nnsc.nsf.net (login: wais), swais.cwis.uci.edu (login: swais), sunsite.unc.edu (login: swais), or info.funet.fi (login: info)

ADDITION (15 May 1993)

The Association of Research Libraries publishes a hardcopy "Directory of Electronic Journals, Newsletters and Academic Discussion Lists" (ISSN: 1057-1337)" edited by Diana Kovacs and Michael Strangelove. This directory is derived from network-accessible files. The section on scholarly discussion lists and interest groups is derived from ACADLIST mentioned above. The section on journals and newsletters is derived from Strangelove's "Directory of Electronic Journals and Newsletters". This directory is available from several

sources, e.g. from LISTSERV@UOTTAWA.BITNET by sending the commands "get Ejourn11 Directory" and "get Ejourn12 Directory". To order the ARL directory contact Gloria Haws, Publications Manager of the Association of Research Libraries, email: osap@cni.org. The price of one copy is USD 42 plus postage, shipping and handling charges.

EXPEDITIONARY ENVIRONMENT RESEARCH & ANALYSIS FRAMEWORK & MODEL 1990

(DRAFT CONCEPT UNDER DEVELOPMENT)

USMC INTELLIGENCE CENTER
MARINE CORPS COMBAT DEVELOPMENT COMMAND
QUANTICO, VIRGINIA
(703) 640-3177/2268 GRAY 980-6109/10

CONTENTS

Brief.....Tab A
Military Capabilities.....Tab B
Operational Geography.....Tab C
Civil Factors.....Tab D
Insurgency Template & Framework Application.....Tab E

21 MAY 1990

OBJECTIVES & PURPOSE OF THE MODEL & SUPPORTING FRAMEWORK

- TO DEVELOP A GENERIC THREAT MODEL USEFUL TO MARINE CORPS PLANNERS & PROGRAMMERS USING THE CONCEPT BASED REQUIREMENTS SYSTEM (CBRS)

- TO DEVELOP A VALIDATED ANALYTICAL FRAMEWORK WHICH IDENTIFIES "CENTERS OF GRAVITY" AND KEY PLANNING & PROGRAMMING FACTORS ABOUT MILITARY CAPABILITIES AND PHYSICAL & HUMAN CONDITIONS AGAINST WHICH INTELLIGENCE ASSESSMENTS SHOULD BE DEVELOPED.

- SET THE STAGE FOR APPLYING THE FRAMEWORK TO COUNTRIES OF INTEREST TO THE MARINE CORPS IN ORDER TO DEVELOP A GENERIC UNCLASSIFIED INTELLIGENCE MODEL OF WHAT CAPABILITIES AND CONDITIONS WILL BE ENCOUNTERED BY THE MARINE CORPS IN THEIR MOST LIKELY AREAS OF OPERATION.

JUSTIFICATION FOR DEVELOPMENT OF A GENERIC FRAMEWORK

- USE OF THE SOVIET/WARSAW PACT AS THE ONLY "WORST-CASE" SCENARIO IS NO LONGER ACCEPTABLE

- THERE ARE ALTERNATIVE "WORST CASE" SCENARIOS IN THE THIRD WORLD WHICH MUST BE CONSIDERED

- IT IS NOT POSSIBLE TO DEVELOP A DETAILED REVIEW OF ALL COUNTRIES, OR ALL THIRD WORLD COUNTRIES, FOR EACH CBRS REQUIREMENT

- WHAT IS NEEDED IS A GENERIC MODEL BASED ON INTELLIGENCE ABOUT FACTORS WHICH PLANNERS & PROGRAMMERS HAVE IDENTIFIED AS IMPORTANT, AND IS:

  -- BASED ON COUNTRY-SPECIFIC REVIEWS FROM WHICH GENERALIZATIONS USEFUL TO CBRS CAN BE DRAWN;

  -- SPECIFIC ENOUGH AT THE UNCLASSIFIED LEVEL TO ENABLE PLANNERS & PROGRAMMERS TO DO ESTIMATES OR EVALUATIONS OF REQUIRED OPERATIONAL CAPABILITIES

  -- GENERAL ENOUGH SO THAT DETAILED & CLASSIFIED COUNTRY-SPECIFIC TECHNICAL ANALYSIS CAN "FIT" INTO AN OVER-ALL PACKAGE USEFUL TO MISSION AREA PLANNERS & PROGRAMMERS

EXPEDITIONARY ENVIRONMENT RESEARCH & ANALYSIS FRAMEWORK 1990

CONDITIONS & CAPABILITIES	HIGH	MEDIUM	LOW
MILITARY CAPABILITY			
OPS GEOGRAPHY			
CIVIL COMPLEXITY			

- FRAMEWORK DESIGN BASED ON COMBINATION OF NOIC BASELINE FOR NAVAL THREAT, IPB PROCESS, ORIGINAL WORK AND WARFIGHTING CENTER CONCEPTS AND PLANS AND MAA CRITERIA.

- AS ANALYTICAL FRAMEWORK DEVELOPS, MUST DEFINE WHAT IS TO BE MEASURED, HOW ("OBSERVABLES") FACTORS CAN BE MEASURED, AND, BASED ON INPUT FROM PLANNERS & PROGRAMMERS, WHY (JUSTIFICATION) FOR DIVIDING LINES BETWEEN "HIGH", "MEDIUM", AND "LOW" THRESHHOLDS FOR EACH FACTOR.

- FRAMEWORK WILL BE VALIDATED THROUGH COUNTRY-SPECIFIC ANALYSIS; VALIDATION WILL LEAD TO SPECIFIC TRUEISMS, GENERIC GENERALITIES, AND DEVELOPMENT OF NEW AND PERHAPS UNANTICIPATED GENERALITIES & SPECIFICS

WHAT THE FRAMEWORK DOES NOT DO

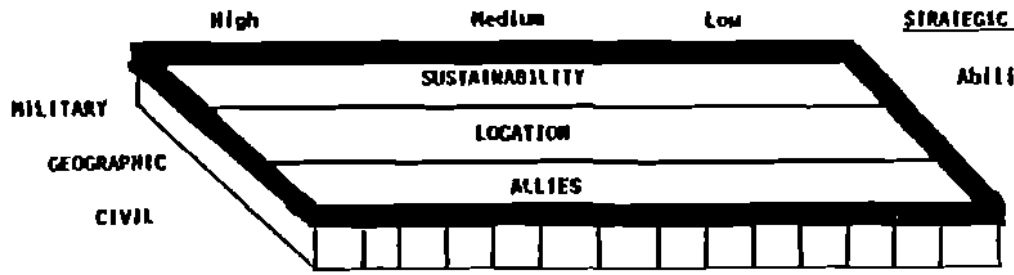
- THE FRAMEWORK DOES NOT PROVIDE CLASSIFIED TECHNICAL INTELLIGENCE PERTINENT TO SPECIFIC COUNTRIES, FACTORS, OR SYSTEMS TO BE EVALUATED

- THE FRAMEWORK DOES NOT PROVIDE "NET ASSESSMENTS" (COMPARISONS & JUDGEMENTS OF FRIENDLY VERSUS ENEMY CAPABILITIES & CONSTRAINTS)

- THE FRAMEWORK DOES NOT PRESCRIBE FRIENDLY REQUIREMENTS OR TACTICAL & OPERATIONAL CAPABILITIES TO BE CONSIDERED BY MISSION AREA PLANNERS & PROGRAMMERS

- THE FRAMEWORK IS NOT "FROZEN" AND WILL BE CONSTANTLY REVISED AS COUNTRIES, FACTORS, AND ACTUAL CONDITIONS & CAPABILITIES CHANGE, PROVIDING PLANNERS & PROGAMMERS WITH A "LIVING DOCUMENT"

CONCEPT OF OPERATIONS FOR INTEGRATED INTELLIGENCE ANALYSIS

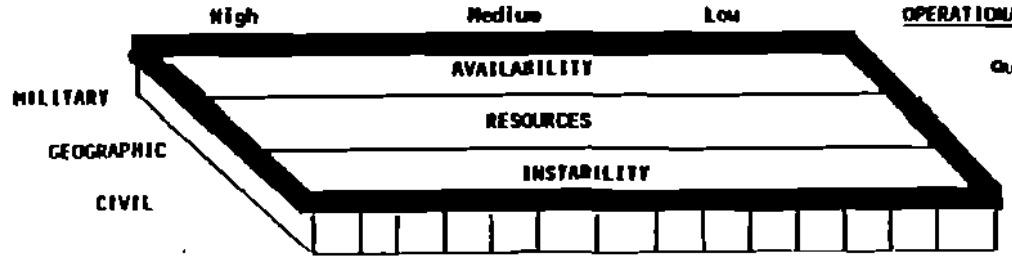


STRATEGIC LEVEL - Integrated Application of all national sources of power

Ability to sustain operations over time & space

Strategic geo-political location or source of materials

External relationships of strategic import

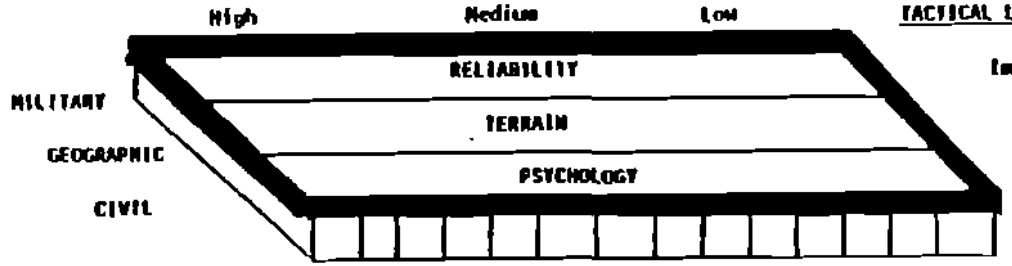


OPERATIONAL LEVEL - Selection of time, space, and nature of engagements

Quantities of military power available for commitment

Internal natural resources .ording self-sustainment

Internal precipitants & preconditions of volatility

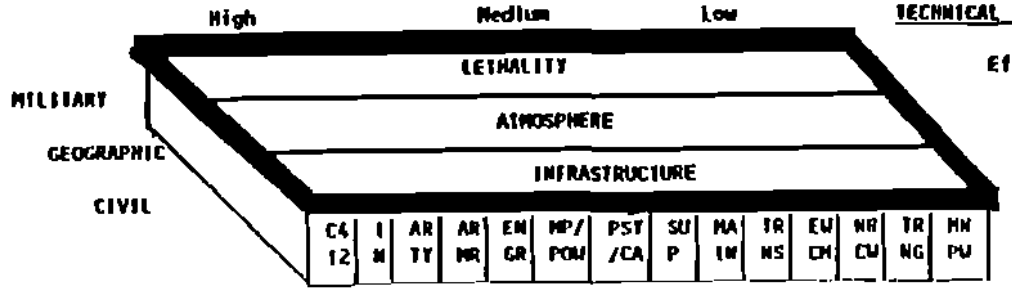


TACTICAL LEVEL - Application of finite power at fixed time & place

Impact of training & maintenance on existing capabilities

Internal geographic conditions affecting mobility

Internal group dynamics affecting cohesion & operations



TECHNICAL LEVEL - System-specific capabilities assessed in isolation

Effectiveness of specific capabilities assuming no constraints

Internal climate affecting system performance

Civilian structures enabling or blocking system use

MISSION AREA ANALYSIS SLICE - Vertical & Horizontal looks

Vertical: through each level of warfare

Horizontal: in relation to geographic & civil factors

EXPEDITIONARY ENVIRONMENT - TERMS OF REFERENCE

Level of Warfare

Strategic	Integrated application of all national sources of power
Operational	Selection of time, space, and nature of tactical engagements in order to attain strategic objectives - theater level
Tactical	Application of finite combat power at fixed time & place
Technical	System-specific capabilities independent of external conditions

Military Capability

Sustainability	Ability to bring to sustain military operations over time & space
Availability	Quantities of military power available for commitment
Reliability	Impact of training & maintenance on existing capabilities
Lethality	Effectiveness of specific capabilities assuming no constraints

Geographic Condition

Location	Strategic geo-political location or source of minerals
Resources	Internal natural resources affording self-sustainment
Terrain	Internal geographic conditions affecting mobility
Atmosphere	Internal atmospheric conditions affecting system performance

Civil Complexity

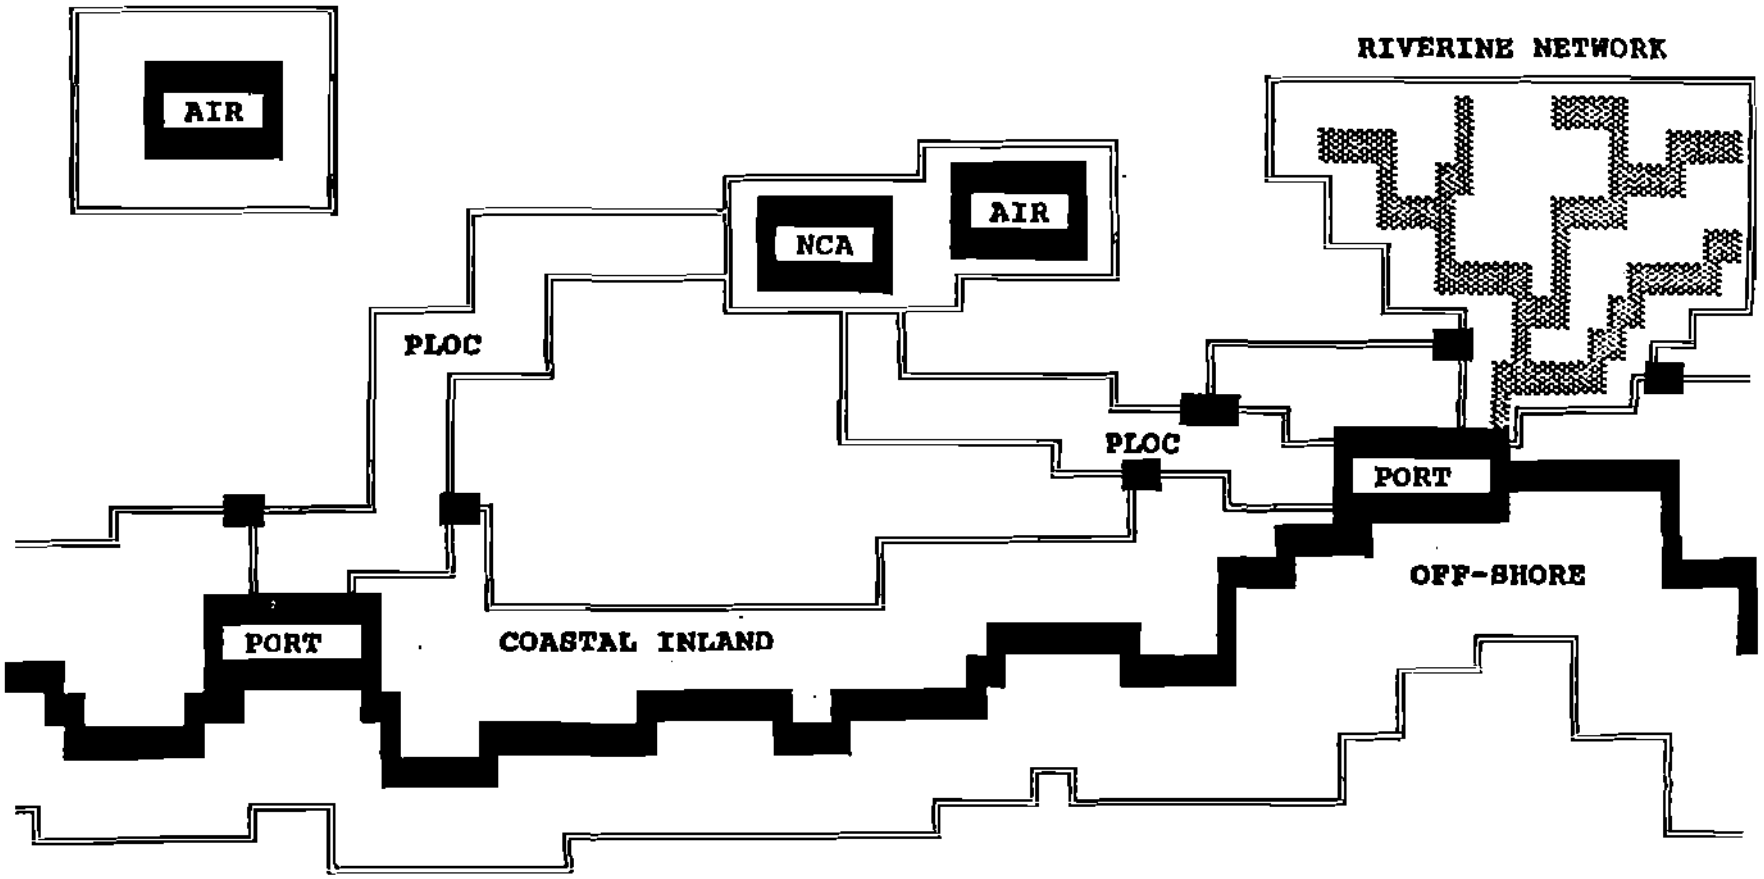
Allies	External relationships of strategic importance
Instability	Internal conditions affecting regime/insurgent effectiveness
Psychology	Internal group dynamics affecting national cohesion
Infrastructure	Internal structures affecting national capabilities

Areas of Operation

Off-Shore	From 25 NM off-shore to high-water mark
Inland Coast	From high-water mark to 50 K inland
PLOC	Primary Line of Communication from Port to NCA + 30 K each side
NCA	National Capital Area + nearest strategic airhead + 30 K around
Internal	Riverine networks, other concentrations of people, military, or key infrastructure nodes

ILLUSTRATION OF EXPEDITIONARY AREAS OF OPERATION

(Method of Delimiting Analysis Problem)



OFF-SHORE:	25 NM TO HIGH-WATER MARK
COASTAL INLAND:	HIGH-WATER MARK TO 50 K INLAND
PLOC:	PRIMARY LINE OF COMMUNICATION FROM PORT TO NCA + 30 K EACH SIDE
NCA:	NATIONAL CAPITAL AREA + NEAREST STRATEGIC AIR HEAD + 30 K ALL ROUND
INTERNAL:	RIVERINE NETWORKS, OTHER STRATEGIC AIR HEADS OR CONCENTRATIONS OF PEOPLE, MILITARY, OR KEY INFRASTRUCTURE NODES

EXPEDITIONARY ENVIRONMENT RESEARCH & ANALYSIS FRAMEWORK 1990
(Early Generalizations)

CONDITIONS & CAPABILITIES	HIGH	MEDIUM	LOW
MILITARY CAPABILITY	Fully integrated high-tech military infrastructure with mobile deep-strike cababilities incl atk air, arty, & SSM followed by mech combined arms force capable of sustained ops	Defined military infrastructure with emerging air-ground strategy. Capable of uncoordinated air & ground attacks, hasty & deliberate defenses, limited reinforcements, withdrawal/delay	Fragmented military infrastructure based on old or poorly defined technologies. Capable of hasty defense and delaying tactics.
OPERATIONAL GEOGRAPHY	Trails, dirt roads in highly forested mountain region over 9000 ft, snowing, temperature below freezing, visibility less than 1000 M	Constrained landing sites, single egress to single land roads in rolling hills w/ scattered trees, to small city. Airfield avail for tacops	Airfield suitable for strategic air transport, rural plain, 40 ft draft port with multiple cranes, piers, and electric power
CIVIL COMPLEXITY	Regional power with allies, fanatical religion, strong international media and propaganda capability, global intel organization, independent energy/food	Garrison state with grass roots support or fragemented unarmed opposition, major urbanization, widespread disease or famine, sufficient water, food, energy	Rural/urban opposition w/local base, limited nat'l intel capability, small elite w/o mass spt, urban/rural mix, no safehaven

NEXT STEPS IN THE DEVELOPMENT OF THE GENERIC FRAMEWORK

- USMC INTELLIGENCE CENTER MUST INITIALLY APPLY ROUGH FRAMEWORK WHICH NOW EXISTS TO A SINGLE COUNTRY TO DETERMINE:
  - -- AVAILABILITY & RELIABILITY OF INFORMATION
  - -- RELEVANCE OF CHOSEN CRITERIA
  - -- IDENTIFICATION OF ADDITIONAL OR ALTERNATIVE CRITERIA
- REFINE FRAMEWORK BASED ON COUNTRY-SPECIFIC ANALYSES.
- DO SUFFICIENT INTERATIONS TO ESTABLISH REPETITIVE PATTERNS AND VALID GENERALIZATIONS.
- RESULTS WILL ESTABLISH "ACCEPTABLE GENERALITIES" WHICH WILL DEFINE THE EXPEDITIONARY ENVIRONMENT MODEL WHILE ACCOMODATING REGIONAL DISTINCTIONS AND COUNTRY-UNIQUE CONDITIONS.

PROCESS FOR DELPHIC USE OF RESEARCH & ANALYSIS FRAMEWORK

FACTOR	HIGH	MEDIUM	LOW
ARTILLERY	SP or towed, with rockets & missiles, NBC, range 30K+	SP or towed, with some missiles, bio-chem, <30K range	Towed artillery with <30K range and/or mortars
MOUNTAINS	High steep slope range with heavy trees cover or low range w/o cover	Low mountain range with scattered trees	Small rolling hills with light scattered trees
OPPOSITION - ORGANIZED - POPULAR	International Opposition with Popular Sympathy	National Opposition with Grass Roots Spt	Rural or Urban Opposition with Only Local Base

- Discuss each factor & description
- Refine descriptions to distinguish between levels
- Categorize level of country for each factor
- Provide one or two bullets justifying each catagorization
- Identify an "observable" for each bullet
- Identify data base or data source for each observable
- Identify collection/processing/production gap if appropriate
- State whether factor is moving higher or lower
- Identify any other factors bearing on categorization

EXAMPLE

LIBYA: POLITICAL-LEGAL/Opposition

- Rated both high and low
- High because of Egypt and Chad
- Low because of Islamic fundamentalists but relative control
- Number of incidents or denunciations by Egypt & Chad can be plotted
- Public references to Islamic fundamentalists can be plotted
- Need automated scanning/extraction of open source print/voice media
- Need improved clandestine HUMINT reporting as well as emigre debriefing

MILITARY CAPABILITIES SHAPING THE EXPEDITIONARY ENVIRONMENT

Executive Summary

- Military capabilities shaping the expeditionary environment should be considered in each of five dimensions:

  -- Ground Overview
  -- C4I2
  -- Combat Support
  -- Combat Service Support
  -- Readiness & Other Factors
  -- Military Manning
  -- Aviation Overview (2)
  -- EW
  -- NBC

- The threat within each dimension can be related to the lethality, range, effectiveness, and sustainability of each capability. For this reason some of the capabilities (e.g. combat arms) will depend on the degree to which other capabilities (e.g. training) are present.

- Examples of a "high", "medium", and "low" environment:

  -- High: A fully integrated high-tech military infrastructure based on an air-ground combined arms strategy utilizing state-of-the-art technologies. Envision a highly mobile, deep-strike capability utilizing ground attack aircraft, long range artillery or SSM's deploying non-persistent CW agents followed by a mechanized combined arms ground force attack to quickly neutralize and destroy opposing forces.

  -- Medium: A defined military infrastructure with an emerging air-ground strategy utilizing current technologies but attempting high-tech systems integration. Envision an enemy capable of uncoordinated air and ground attacks, hasty and deliberate defenses, limited reinforcements, withdrawal and delaying tactics.

  -- Low: A fragmented military infrastructure with segregated military capabilities based on obsolete or ill-defined technologies. Envision an enemy capable of hasty defense and delaying tactics only.

OVERVIEW OF GROUND FACTORS SHAPING THE EXPEDITIONARY ENVIRONMENT

CAPABILITY	HIGH	MEDIUM	LOW
INFANTRY	Mechanized, division-sized combined arms capable with ALP	Mobile trained Rgmts or Bns with some combined arms	Bn-sized forces with limited mobility & spt
ARTILLERY	SP or towed, with rockets & missiles, NBC, range 30K+	SP or towed, with some missiles, bio-chem, <30K range	Towed artillery with <30K range and/or mortars
ARMOR	T-72MI or T-80/64B equivalent with advanced armor (R/A)	M-60, T-62E/Mod 55 equivalent with 3rd gen. armor	M-48/T-54/IFV equivalents or less
C4I2	Integrated strategic & tactical C4I2 using full RF spectrum	Terrestial RF and landlines, limited encryption & intel	Single-channel radio, limited encryption/intel
SUPPORT	Full-range engineers, complete military police/PSYOP-CA units,	Limited engineers, some military police and PSYOP-CA	Countermobility engineering, no dedicated MP/PSYOP
SERVICE SUPPORT	Able to move, supply, & maintain a division beyond its borders	Can move, supply, & maintain rgmts & bns within borders	Some resupply & limited maint. capability
LEADERSHIP, TRAINING, & READINESS	Corps+ leaders, troops experienced, well-trained, fully ready	Div level leaders, some troop training partially ready	Regt lev leaders, no or infrequent training, not rdy
MILITARY MANNING	Foreign advisors, full reserve, PM/elite units	Foreign contractors, partial reserves, some PM/elite units	Constabulary or pro forma reserve w/o SOF

C4I2 FACTORS SHAPING THE EXPEDITIONARY ENVIRONMENT

CAPABILITY	HIGH	MEDIUM	LOW
COMMAND & CONTROL & COMMUNICATIONS	Integrated automated C4 btw NCA & ground/ air hqs; national/alt. CP, full RF & SATCOM, encryption all levels	Limited C4 automation w/reliance on land-lines & terrestial RF w/strategic encryp-tion, tac. ops codes	No integration or automation of C4, use single channel radios (e.g. HF), offline encry/clear
COMPUTING	Mainframe & high performance distributed processing, ADP tools	Limited use of stand alone workstations, basic PC packages	Manual data process-ing and report production
INTELLIGENCE & INTEROPERABILITY	Multi-discipline collection capability w/all-source analysis at national & tactical levels	Strategic intel from allies, some SIGINT, IMINT, HUMINT collec-tion, limited inte-gration	Limited strategic intel from allies, national HUMINT, tactical SIGINT, no/ limited IMINT

COMBAT SUPPORT FACTORS SHAPING THE EXPEDITIONARY ENVIRONMENT

CAPABILITY	HIGH	MEDIUM	LOW
ANTI-TANK	PGM, atk helo, self-propelled AT, arty/air deliverable mines	SP AT, RR, arty/air deliverable mines	Crew served or shoulder launched AT weapons
ENGINEERS	Heavy equipment, can do mobility/countermobil., survivability, gen eng.	Few heavy assets, can do minefields & obstacles, demolit.	Manual minefield & obstacle construc. & clearing
MILITARY POLICE	Dedicated organized MP units able to handle mass refugee/POW groups	Limited organized MP units able to handle routine matters	No dedicated MP units; law enforcement by infantry
PSYOP & CIVIL AFFAIRS	Dedicated organized PSYOP/CA units with organic equipment	Limited organized PSYOP/CA specialists detailed to infantry	No organized PSYOP or CA capabilities

COMBAT SERVICE SUPPORT FACTORS SHAPING THE EXPEDITIONARY ENVIRONMENT

CAPABILITY	HIGH	MEDIUM	LOW
SUPPLY	Self-sufficient, can sustain combat ops for over 6 months, to include external ops	Self-sustaining up to 6 months, rely on allies for supplies	Self-sustaining for less than 30 days, rely on allies/raids
MAINTENANCE	Unit, intermediate, & depot-level	Unit & intermediate (DS & GS units), external depot spt	Unit level only. Dependent on external manning & facilities
TRANSPORTATION	Modern assets, fast response, not reliant on commercial assets	Good rail & roads, limited air, partial use of commercial	Primitive or limited transport, slow response, commercial

READINESS & OTHER FACTORS SHAPING THE EXPEDITIONARY ENVIRONMENT

CAPABILITY	HIGH	MEDIUM	LOW
LEADERSHIP	Combat experience, Corps-level staffs, professional schools	Ops/exercises done, div-level staffs, few foreign advisors	Regiment-level staffs, rely on foreign advisors
TRAINING	Training at division level or higher, 3-5 days per month	Training at rgmt or lower level, 1-3 days per month	Infrequent training at/below 1 day per month
READINESS	All equipment receives preventive maintenance from trained personnel	Most equipment in ready status, is repaired as needed	Generally poor maintenance, most equipment deficient

MILITARY MANNING FACTORS SHAPING THE EXPEDITIONARY ENVIRONMENT

CAPABILITY	HIGH	MEDIUM	LOW
FOREIGN ADVISORS	In-country, providing R&D or intel support, of manning equipment	Intel & operational advisory role, MTTs, liaison/oversight	Temporary travel in-country for MTT or supply purposes
CONTRACTORS	Fully responsible for manning and/or maint. of critical systems	Responsible for maintenance & testing of key systems	Temporary travel in-country for installation/repair
RESERVES	Organized trained reserve able to fill range of combat needs	Organized coastal, constabulary, or specialty units	No organized units or regular training
PM/SOF/ELITE	Trained & specially equipped units with unique status	Organized units with special roles and loyalties	No organized PM, SOF, or elite units

OVERVIEW OF AVIATION FACTORS SHAPING THE EXPEDITIONARY ENVIRONMENT

CAPABILITY	HIGH	MEDIUM	LOW
AIR SURVEILLANCE WEAPONS SUPPORT	Full integrated air defense net, with digital automation	2nd/3rd generation Soviet/Western IAD	Limited IAD netting with landline links
FIGHTER AIRCRAFT (FIXED & VSTOL)	4th generation Soviet / Western full LD/SD capability	3rd generation Soviet /Western limited LD/SD cap	Early jets with limited scramble, no sustained CAP
STRIKE AIRCRAFT (FIXED & VSTOL)	All-weather medium & long-range, NBC capable	Marginal all-weather medium/long range without NBC	Day only, VFR delivery
HELICOPTERS (BOTH ATTACK & TRANSPORT)	4th gen. attack & transport	3rd gen. attack & transport, limited assets	No military assets, limited commercial assets
SURFACE TO AIR MISSILES	4th Gen Soviet/Western Strategic / Tactical Improved IR	3rd Gen Soviet/West Strategic/Tactical	Hand Held Tactical IR Only
ANTI-AIRCRAFT ARTILLERY	4th Gen Soviet/West Radar associated Mobile	3rd Gen Soviet/West limited radar restricted mobile	Small arms Optical sighting Manual operations
AIR TO AIR MISSILES	4th Gen Soviet/West Dual Mode True All-Aspect	3rd Gen Soviet/West Limited All-Aspect	Early IR/SAR Rear Quarter

OVERVIEW OF AVIATION FACTORS SHAPING THE EXPEDITIONARY ENVIRONMENT

CAPABILITY	HIGH	MEDIUM	LOW
RECONNAISSANCE	Long-range dedicated platform with real-time links	Medium/long-range multi-role platform w/NRT links	Low mission priority with no NRT links
AIRBORNE EARLY WARNING/CONTROLLER (AEW)	Long-range/extended loiter time, multi-mission, digital links	Single mission ops w/limited coverage, voice links	No capability
TACTICAL ELECTRONIC WARFARE (TACEW)	Dedicated platform ESM/ECM, both fixed wing & rotor	Self-protection only or helo platforms only for ECM	No capability
TRAINING & READINESS	Simulators, live fire & free play; sustain support all levels	Limited training & live fire; foreign support at depot	Less than 10 hours flight/month; rely on foreign support

NBC FACTORS SHAPING THE EXPEDITIONARY ENVIRONMENT

CAPABILITY	HIGH	MEDIUM	LOW
NUCLEAR	Stockpiled nuclear weapons or proven capability to build	Advanced R&D effort, component acquisition, prototypes	No nuclear capability or capacity to develop
CHEMICAL	Indigenous production, full spectrum, prior utilization	Stockpiles of major agent, indigenous or foreign production	Foreign procurement, non-persistent, limited stocks
BIOLOGICAL	Indigenous production, full spectrum of toxic & infectuous agents	Microbiology R&D, some infectuous agents in stock	Foreign procurement would be needed, no agents in stock
DELIVERY	Full range of air & missile/artillery delivery systems	Artillery & mortar delivery, some air (rotary) delivery	No tested delivery system

EW FACTORS SHAPING THE EXPEDITIONARY ENVIRONMENT

CAPABILITY	HIGH	MEDIUM	LOW
EW SUPPORT MEASURES (ESM)	Automated netted COMINT & ELINT w/DF, capable against full spectrum & w/full proc/rpt	Manual collection & DF against some comms & non-comms signals	Limited or no collection
ELECTRONIC COUNTER MEASURES (ECM)	Mobile programmable jamming/deception, full spectrum, active & passive, varied tech.	Capable of jamming & deception within specific frequency ranges	Limited or no jamming/deception capability (can do ICD obvious jamming)
ELECTRONIC COUNTER-COUNTER MEASURES (ECCM)	Fully developed and exercised system of preventive & remedial measures/equipment	Some doctrine & equipment	Non-existent system or limited to operator training

OPERATIONAL GEOGRAPHY SHAPING THE EXPEDITIONARY ENVIRONMENT

Executive Summary

- Operational geography shaping the expeditionary environment should be considered in each of six dimensions:

  - -- Basic Topography
  - -- Assault Hydrography
  - -- Operational Infrastructure
  - -- Ground Assault Conditions
  - -- Aeronautical Conditions
  - -- Basic Weather

- The threat within each dimension can be related to the degree to which topographical and/or weather conditions constrain operational mobility, firepower, and/or sustainability.

- Examples of a "high", "medium", and "low" environment for these factors is offered below:

  - -- High: Trails, dirt roads in a highly forested mountain region over 9000 ft, snowing, temperature at 0, visibility less than 1000 meters, with objective too far inland to permit sea-launched assault and naval gunfire support.

  - -- Medium: Single amphibious landing vehicle sites with egress to single lane hard surface roads and rail roads, small rolling hills with moderate scattered trees, to a small city. Airfield suitable for sustained tactical air transport operations.

  - -- Low: Airfield suitable for sustained strategic air transport. Rural plain, 40 ft draft port facility that has multiple cranes, piers and electric power.

OPERATIONAL GEOGRAPHY SHAPING THE EXPEDITIONARY ENVIRONMENT

BASIC TOPOGRAPHY	GROUND ASSAULT	ASSAULT HYDROGRAPHY	AERONAUTICAL CONDITIONS	OPERATIONAL INFRASTRUCTURE	BASIC WEATHER
Surface Configuration	Cover	Beaches	Ops Elevation	Port Access	Temperat.
Surface Vegetation	Concealment	NGF (5 fathom line)	Aerial Visibility	Port Utility	Windspeed
Surface Materials	Inter-Visibility	Surf Conditions	Aerial Ceiling	Air Terminals	Precipit.
Surface Hydrology	Landing Zones	Approach Conditions		Road/Rail Net	Humidity
Man-made Features	Drop Zones	Riverine Network		Bridges	Light Data

BASIC TOPOGRAPHY FACTORS SHAPING THE EXPEDITIONARY ENVIRONMENT

CONDITION	HIGH COMPLEXITY	MEDIUM COMPLEXITY	LOW COMPLEXITY
SURFACE CONFIGURATION	High steep slopes of >40%, ranges with ravines & embankments	Low ranges with small ditches and scattered outcrops	Small rolling hills with valeys and flat areas
SURFACE VEGETATION	Double & triple canopy with heavy dense trees and dense undergrowth	Single canopy with mix of vegetation and open bare ground	Shrubs & grasses on flat plains including cactus or eleph. gr.
SURFACE MATERIALS	Wet clay, silt, large gravel or drifing loose sand, sebkhas & wadis	Moist sand, small gravel or loose unsettled sand	Dry silt, clay, small gravel or flat hard plain w/o sebkhas
SURFACE HYDROLOGY	Lakes, swamps, rivers, and/or glaciers; boats required for crossings	Streams, canals, small rivers; fording equipment needed	Seasonal streams, creeks, no major water obstacles
MANMADE FEATURES	Urban areas, major oil fields, major bridges or tunnels/pipelines	Sururban or village areas, minor power facilities, bridges	Predominantly rural, minor bridges and/or tunnels, few obstacl.

GROUND ASSAULT CONDITIONS SHAPING THE EXPEDITIONARY ENVIRONMENT

CONDITION	HIGH COMPLEXITY	MEDIUM COMPLEXITY	LOW COMPLEXITY
COVER	Flat plains and wide open areas	Moderate scattered trees on rolling hills	Densely wooded areas within low mountain range
CONCEALMENT	75% or more canopy closure	40-74% canopy closure	0-39% canopy closure
INTER-VISIBILITY	Average line of sight distance in AO is less than 1000 meters	Average line of sight in AO is 1000 to 3000 meters	Average line of sight in AO is over 3000 meters
LANDING ZONES	Slope of available LZ/HLZ greater than five degrees	Slope of available LZ/HLZ 3-5 degrees	Slope of available LZ/HLZ <3 degrees
DROP ZONES	Few or very small clearings with no ground access/exits	Small playing field size clearings with limited exits	Large open fields with many exits & access to LOCs

ASSAULT HYDROGRAPHY CONDITIONS SHAPING THE EXPEDITIONARY ENVIRONMENT

CONDITION	HIGH COMPLEXITY	MEDIUM COMPLEXITY	LOW COMPLEXITY
BEACHES	Limited or not avail, with restricted or channeled egress	Sufficient to allow single LCAC or few LAV, multiple egress	Multiple sites for full LAV waves, multiple egress
NAVAL GUN FIRE	5 fathom line more than 16K meters offshore	5 fathom line is >8K <16K meters offshore	5 fathom line is less than 8K meters offshore
SURF CONDITIONS	>3.5 ft. swells, >4.0 ft. surf, underlying current >3 kts	2-3 ft. swells, 2-4 ft. surf, under-current 2-3 kts	0-1 ft. swells, 0-1 ft. surf, under-current < 2 kts.
APPROACH CONDITIONS	>15 ft. tidal range, or slope <1:5 and/or silty/muddy bottom	>5' <15' tidal range and/or slope >1:5 <1:10, sand	<5' tidal range, or slope >1:5 and/ or hard bottom
RIVERINE NETWORK	Major river complex with tributaries >6' deep and ocean access	Defined network w/ streams >3' <6' deep, mostly inland	Seasonal streams <3' deep

AERONAUTICAL CONDITIONS SHAPING THE EXPEDITIONARY ENVIRONMENT

CONDITION	HIGH COMPLEXITY	MEDIUM COMPLEXITY	LOW COMPLEXITY
ELEVATION	Over 9000 ft	4000-9000 ft	Less than 4000 ft
AERIAL VISIBILITY	Less than 2 NM	>2 <5 NM	Over 5 NM
AERIAL CEILING	Less than 1000 ft	3-5K ft +/-	Over 10K ft +/-

OPERATIONAL INFRASTRUCTURE CONDITIONS SHAPING THE EXPEDITIONARY ENVIRONMENT

CONDITION	HIGH COMPLEXITY	MEDIUM COMPLEXITY	LOW COMPLEXITY
PORT ACCESS	Less than 34' draft (tactical assault)	35-40' draft (gray shipping)	Over 40' draft (black shipping)
PORT UTILITY	No cranes or piers	At least one crane or pier per port	Multiple cranes & piers, electric power available
AIR TERMINALS	Not good for tactical transport ops, no ground control	Suitable for fully loaded tactical transport ops	Suitable for strategic airlift
AIRHEAD UTILITY	One or no ramps	Two to five ramps, some fuel storage and bunker areas	Five or more ramps suitable for C-5, good fuel/ammo site
ROAD/RAIL NETWORK	Trails, dirt roads, very limited or no railroad	Hard surface single lane roads, single track RR	Major highways, extensive RR
BRIDGES	Many primitive or old bridges of low or unknown load bearing	Mix of steel/cement bridges w/load bearing <20 tons	Modern steel & cement bridges with >20 ton capability

BASIC WEATHER FACTORS SHAPING THE EXPEDITIONARY ENVIRONMENT

CONDITIONS	HIGH COMPLEXITY	MEDIUM COMPLEXITY	LOW COMPLEXITY
TEMPERATURE	>80 <32 F	32-50 or 65-80 F	51-64 F
WIND SPEED	>30 knots	13-30 knots	<13 knots
PRECIPITATION	1"/hour or 2"/12 hrs; 2" snow/hour or 6" snow/12 hrs	.5-1"/hour or 1"/ 12 hrs; 1-2" snow/ hr or 3-6"/12 hrs	0-.5"/hour or .5"/ 12 hrs; 0-1" snow/hr 0-3"/12 hrs
HUMIDITY	60-100%	31-59%	12-30%
LIGHT DATA	4-6 hrs daylight	6-10 hrs daylight	>10 hrs daylight

CIVIL FACTORS SHAPING THE EXPEDITIONARY ENVIRONMENT

Executive Summary

- Civil factors shaping the expeditionary environment should be considered in each of five dimensions:

  -- Political
  -- Psychological
  -- Economic
  -- Infrastructure
  -- Natural Resources

- The complexity of the factors, increasing the difficulty facing the tactical commander, can be related to the area of influence of each factor: International = HIGH, National = Medium, Local/Urban = LOW.

- The relevance of the factors to expeditionary operations can be established by determining whether the factor must be considered in relation to short-term missions under 7 days (e.g. a NEO), mid-term missions over 7 but under 30 days (e.g. humanitarian assistance) and longer-term missions over 30 days (e.g. internal security).

- Examples of a "high", "medium", and "low" environment for these factors is offered below:

  -- High: Regional power with allies, fanatical religion, strong international media and propaganda capability, global intelligence organization, and independent energy & food supplies.

  -- Medium: Garrison state with grass roots support or fragmented unarmed opposition, major urbanization, widespread disease or famine, sufficient water, food, energy.

  -- Low: Rural/urban opposition with local base, limited national intelligence capability, small elite without mass support, balanced mix of urban & rural populations, secure borders offering no safehaven.

CIVIL FACTORS - TERMS OF REFERENCE

Civil Dimensions

Political.....	**Focus on political relationships between groups and individuals, including external allies and internal opposition groups; and on basic capabilities and legal environment maintaining government control of political process.**
Psychological.....	**Focus on the ideological and cultural nature of the population and the degree to which individual behavior undermines or supports the nation-state. Assesses role of religion & language as divisive or cohesive factors, group divisions & customs, national myths, and other issues associated with individual education & rebellion.**
Economic.....	**Focus on ability of state to fulfill its functions and allocate resources, with emphasis on the stability of the consumer market, the role of the military as a dominant group, the general stregth of the economy, and the degree to which capital is available and research & development sponsored for future economic power.**
Infrastructure.....	**Focus on the technical and demographic resources of the nation-state including basic issues regarding population distribution, disease, communications, public works, public transportation, and electronic computing resources.**
Natural Resources.....	**Focus on natural resources including water, food, energy, and mineral wealth, as well as related issues which contribute to conflicts, such as contiguous hostile areas, land tenure practices, and production base constraints.**

CIVIL FACTORS SHAPING THE EXPEDITIONARY ENVIRONMENT

POLITICAL	PSYCHOLOGICAL	ECONOMIC	INFRASTRUCTURE	NATURAL RESOURCES
Allies	Religion & Language	Strikes & Riots	Key Facilities & No Fire Areas	Contiguous Hostile Area
Opposition	Group Divisions, Customs/Taboos	Black Market, Corruption, & Mil/Pol Crime	Urbanization & Population Issues	Water Supply
Intelligence	Myth/Identity, Media Themes, & View of USA	Unemployment & Inflation	Disease & Public Health Resources	Food Supply
Government	Education	Basic Civilian Staples/Supply	Public Voice/Print Media & Telecommunications	Energy Supply
Human Rights	Intellectuals	Garrison State	Public Works (Power & Water)	Strategic Minerals & Raw Materials
Public Form, Franchise, & Opinion	Censorship	Foreign Capital & Capital Flight	Public Transportation Assets	Production Base
Legal Codes	Violence	R&D Program	Electronic Computing & Storage	Land Tenure

POLITICAL FACTORS SHAPING THE EXPEDITIONARY ENVIRONMENT

CONDITION	HIGH COMPLEXITY	MEDIUM COMPLEXITY	LOW COMPLEXITY
ALLIES	Major hostile power or several regional powers	Major regional power or scattered minor supporters	No major ally in region nor Sov/PRC interest
OPPOSITION - ORGANIZED - POPULAR	International Opposition with Popular Sympathy	National Opposition with Grass Roots Spt	Rural or Urban Opposition with Only Local Base
INTELLIGENCE - STRUCTURED - PROFESSIONAL	International Intelligence with Global Assets	National Intelligence with Rural/Urban Assets	Limited Intelligence with Capital City Base
GOVERNMENT - STRUCTURED - RESPONSIVE	Fully capable sovereign government	Nationally capable government with limited int'l role	Parochial or unformed state w/limited powers
HUMAN RIGHTS	Violent repression w/o oversight of police &/or military	Limited repression w/some political oversight/pressure	Firm commitment to human rights, broad public pressure
PUBLIC FRANCHISE & OPINION - LEGITIMACY	Unrestricted citizen base with protected rights	Partial franchise with popular majority	Very restricted elite without majority support
LEGAL CODES - EXISTENCE - EFFECTIVE	Religious or primitive codes or patron power	Legal or religious codes partially or arbitrarity used	Established legal system with working courts

* Includes gender mix and stratification of population by class, race, [illegible], or religion.

PSYCHOLOGICAL FACTORS SHAPING THE EXPEDITIONARY ENVIRONMENT

CONDITION	HIGH COMPLEXITY	MEDIUM COMPLEXITY	LOW COMPLEXITY
RELIGION & LANGUAGE	Intense national religion or varied opposed religions; "hard" language	Major religion or mass movement with active role; Western language	Western or varied religions of no real influence; Eng/Frnch/Spnsh
GROUP DIVISIONS, CUSTOMS, AND TABOOS	Major fragmentation of society with conflicting mores	Major minority element not fully integrated	No significant socio-economic fragmentation
MYTH/IDENTITY, MEDIA THEMES, & VIEW OF USA	Cohesive national myth system, with xenophobic nature	Strong national identity and sense of history	Limited or fragmented myth system/identity
EDUCATION - PUBLIC - QUALITY	No public schools and a primitive illiterate public	Partial public education, literate urban population	Public education and literate population
INTELLECTUALS - EXISTENCE - COMMITMENT	Strong intellectual community firmly committed to state	Isolated community of intellectuals including exiles	Fragmented or unformed community of intellectuals
CENSORSHIP - SCOPE - DEGREE	Total censorship of all media and all topics	Censorship of political topics or select groups	Limited or no censorship
VIOLENCE - PRE-DISPOSED - EXTENT	Cultural pre-disposition and history of violence	Elite history of unchecked violence	No significant pre-disposition or history

ECONOMIC FACTORS SHAPING THE EXPEDITIONARY ENVIRONMENT

CONDITION	HIGH COMPLEXITY	MEDIUM COMPLEXITY	LOW COMPLEXITY
REBELLION (RIOTS, STRIKES, DEMONSTRATIONS)	Frequent and sustained public riots & strikes	Occasional violent rebellion or many demonstrations	Limited and generally peaceful gatherings
BLACK MARKET & CORRUPTION & MIL/POLICE CRIME	Thoroughly corrupt society, bribes for basic transactions	Limited elite corruption, some bribes necesary	Limited elite corruption, no major monopolies
INFLATION & UNEMPLOYMENT - RATE	Rapid rate of inflation and high unemployment	Fluctuating rates of inflation and unemployment	Steady or limited inflation and unemployment
BASIC CIVILIAN STAPLES/SUPPLY - TYPE/EXTENT	Major shortages of basic staples and household items	Shortages of convenience items & minor luxuries	Full range of staples and consumer goods
GARRISON STATE - MONOPOLY - ISOLATED	Dictatorship or entrenched military controlling economy	"Benevolent" or professional military elite	Militia or home guard with limited role
FOREIGN CAPITAL & CAPITAL FLIGHT	Most elite funds withdrawn and no foreign credit	Steady capital flight, high rates of loan interest	Modest capital flight, steady foreign loans
R&D PROGRAM - FUNDED - QUALITY	National R&D program with high-tech goals	Private industry R&D in some areas	No significant R&D program

INFRASTRUCTURE FACTORS SHAPING THE EXPEDITIONARY ENVIRONMENT

CONDITION	HIGH COMPLEXITY	MEDIUM COMPLEXITY	LOW COMPLEXITY
KEY FACILITIES & NO FIRE AREAS	Regionally important facilities, many no fire areas	Nationally vital facilities, some no fire areas	No major facilities requiring control, minor no fire areas
POPULATION ISSUES - URBANIZATION - DISPLACEMENT	Excessive and unsupportable urbanization	Major urbanization with limited or sporadic services	Balanced mix of urban & rural populations
DISEASE & HEALTH - SCOPE - ADDRESSED	Uncontrolled famine and/or disease such as AIDS/schistosom.	Major disease such as schistosomaisis and public program	No major disease or famine and/or good public plan
PUBLIC COMMS - VOICE/PRINT MEDIA - TELECOMMUNICATION	Int'l media & propaganda, int'l telecommunications	National media and propaganda capability	Primitive media & limited nat'l telecommunications
PUBLIC WORKS - POWER - WATER	No established public works system	Partial public works and/or frequent breakdown	Established and functional public works system
PUBLIC TRANSPORTATION ASSETS	Major transport fleets with int'l infrastructure	Substantial ground transport fleet w/ national network	Some urban assets w/generally poor roads or rails
ELECTRONIC COMPUTING & STORAGE	National network of electronic data entry & management assets	Strong program of data management in primary industry	Limited or old data storage and management tools

NATURAL RESOURCE FACTORS SHAPING THE EXPEDITIONARY ENVIRONMENT

CONDITION	HIGH COMPLEXITY	MEDIUM COMPLEXITY	LOW COMPLEXITY
EXTERNAL THREAT - CONTIGUOUS - MAJOR POWER	Major hostile power on border	Minor or neutral power on border allowing safehaven	Secure borders offering no safehaven
WATER SUPPLY - LOCAL - RELIABLE	Importer of water or scarce water resources	Sufficient natural water for basic needs	Major rivers and lakes with good water works
FOOD SUPPLY - LOCAL - RELIABLE	Importer of basic foods	Nationally self-sufficient in basic foods	International supplier of major edible commodity
ENERGY SUPPLY - LOCAL - RELIABLE	International supplier of oil or electricity	National reserves of energy, partial exploitation	Importer of oil and/or electric power, coal
STRATEGIC MINERALS & RAW MATERIALS	International supplier of major minerals/materials	National reserves of basic minerals and materials	Importer of basic minerals and materials
PRODUCTION BASE - SINGLE/MULTIPLE - EXPLOITED	Over-reliance on single sector and/or weak market	Strong single sector with good distribution	Balanced mix of production (both indus. & agri.)
LAND TENURE - DISTRIBUTED - EFFECTIVE	Well distributed and exploited land holdings	Limited land tenure, strong share-cropping	Restrictive land tenure, serf-like labor conditions

"SO WHAT" TEST FOR CIVIL FACTORS

NOTE: Unlike military conditions and operational geography, the relevance of civil factors to normal MAGTF planning & programming activities may not be as apparent. Although the Small Wars Manual and other doctrinal publication recognize the importance of psychological and civil affairs, and the are clearly defined intelligence requirements associated with these functions as well as engineering, motor transport, and so on, the above matrix sought to bring together the various "civil" factors as a means of integrating them in the intelligence estimates process and highlighting the co-equal status of civil factors when planning for stability operations and limited objective operations.

Political

Allies	**Potential for intervention and/or mobilization of regional or international opinion**
Opposition	**Potential of existing groups (both armed and unarmed) for assisting or opposing MARFOR**

Intelligence	**Potential of intelligence & security services for assisting or opposing MARFOR operations, both internally and through covert actions & propaganda activities outside the AO (including against domestic U.S. public)**
Government	**Potential for assisting or opposing MARFOR**

Human Rights	**Establishes degree to which individuals have been repressed, and possible need for remedial programs; includes degree to which entrepreneurship present & successful**
Franchise	**Insights into nature of public's political personality, degree to which public opinion can aid or hamper MARFOR and/or government**
Legal Codes	**Foundation of internal order**

Psychological

Religion & Language	**Degree of difficulty for MARFOR intel, PAO, and engineers; includes religious codes and language conventions which MARFOR must understand**
Group Divisions, Customs/Taboos	**Degree to which certain groups must be monitored and MARFOR behavior adjusted**
Myth/Identity, Media Themes, & View of USA	**Provides MARFOR with estimate of cohesiveness of population, understanding of popular propaganda themes, and attitudes toward USA**
Education	**Establishes degree of popular literacy in relation to MARFOR public information program and public understanding of issues**
Intellectuals	**Establishes location & nature of key leaders of public opinion and degree to which they might oppose/support MARFOR ops**
Censorship	**Establishes degree to which public has been misinformed, and degree to which MARFOR must undertake remedial public information program**
Violence	**Establishes degree to which local population is culturally pre-disposed to violence, and alerts MARFOR to potential volatility**

Economic

Rebellion	Degree to which population supports insurgents and/or might impact MARFOR ops
Black Market, Corruption, & Mil/Pol Crime	Orients MARFOR to local "norms" (including need for MARFOR discretionary funds) as well as general dislocation of economy and degree to which local forces are regarded as "predators"
Inflation & Unemployment	Degree to which economic dislocation exists that may interfere with long-term MARFOR ops
Basic Civilian Staples/Supply	Degree to which civilians lack staples for diet or consumer goods which MARFOR must provide, or which MARFOR can draw upon in lieu of external resupply
Garrison State	Degree to which AO is militarized
Foreign Capital & Capital Flight	Presence or absence of foreign equities and/or flight of internal capital may complicate conditions for MARFOR
R&D Program	Identifies degree to which military R&D might threaten MARFOR, and general health of local R&D effort as it supports prosperity

Infrastructure

Key Facilities & No Fire Areas	**Identifies key facilities requiring MARFOR protection and possibly operation, and key sites (archives, monuments, etcetera) that constrain MARFOR ops**
Population Issues	**Establishes concentrations of people that MARFOR must deal with, and potential for displaced persons, refugees, and groups requiring MARFOR control or support**

Disease & Public Health Resources	**Identifies major diseases dangerous to individual Marines, degree to which local health resources are present or absent, extent to which MARFOR must provide medical reinforcements**
Public Comms (Voice/Print Media & Telecomms)	**Identifies degree to which existing local media outlets can be mobilized to meet MARFOR public information requirements; also availability of commercial telecommunications to be controlled, monitored, or exploited**

Public Works	**Degree to which public utilities (power & water) can be relied upon or must be managed by MARFOR engineers; identification of key nodes to be controlled or protected**
Public Transport	**Degree to which civilian transportation assets can be used to support or oppose mid-term MARFOR stability ops (actual infrastructure covered in Operational Geography)**

Natural Resources

Contiguous Hostile Areas	Establishes whether or not safehaven areas are available for opposing forces, and whether direct overland logistics resupply is possible. Identifies expanded AO.
Water Supply	Identifies degree to which water supply might constrain MARFOR as well as local elements, and whether engineer support will be needed to assure water for MARFOR and/or civilians
Food Supply	Identifies degree to which food supply might constrain local elements, and whether engineer spport and imported staples will be required for civilians
Energy Supply	Identifies degree to which energy supply might constrain MARFOR as well as local elements, and whether engineer support will be needed to assure energy for MARFOR and/or civilians
Strategic Minerals & Raw Materials	Identifies presence or absence of minerals & & raw materials critical to production of war supplies as well as national economy
Production Base	Identifies income-producing areas or lack of alternatives which may constrain long-term stability & undermine internal security
Land Tenure	Orients MARFOR regarding existing land distribution/exploitation practices which may stimulate long-term hostility in rural area and/or require civilian assistance

INSURGENCY FACTORS SHAPING THE EXPEDITIONARY ENVIRONMENT

Executive Summary

- Insurgency factors shaping the expeditionary environment all fall within existing factors under the military and civilian elements of the framework for expeditionary analysis. However, in recognition of their importance, and the efforts of the Army-Air Force Center for Low Intensity Conflict, this section builds on the results of the "Indicators Templating" Study, and presents a tailored framework for drawing high-level generalizations about insurgency factors.

- The five matrices extracted from the Study and then refined or expanded include:

  -- Insurgent Military Capabilities
  -- Insurgent Civil Factors
  -- Insurgent Event Data
  -- Host Country Military Capabilities
  -- Host Country Civil Factors

- Examples of a "high", "medium", and "low" environment for these factors is offered below:

  -- High:

  -- Medium:

  -- Low:

INSURGENCY FACTORS SHAPING THE EXPEDITIONARY ENVIRONMENT

INSURGENT MILITARY CAPABILITIES	HOST COUNTRY MILITARY CAPABILITIES	INSURGENT CIVIL FACTORS	HOST COUNTRY CIVIL FACTORS	INSURGENT EVENT DATA
Commitment to Terrorism	Leadership	Overt Political Mobilization	Police Operations	Bombings
Capability for Terrorism	Military Intelligence	Covert Political Mobilization	Civilian Intelligence Operations	Kidnapping & Assassination
Safe-Haven or Controlled Territory	Troop Discipline & Behavior	Propaganda	Civil-Military Relations	Civil Disobedience
Steady Flow of Weapons & Trained G's	Use of Popular Militia	Civil Acquisition	Unified Management	Strikes & Riots
Established Military Organization	Force Structure	Funding Mechanism	Psychological Operations	International Media Events
Acquisition of Crew-Served Wpns & Vehicles	Strategy	Indoctrination Mechanism	Political Environment	Conventional Military Ops
Established C4I2 Networks	Tactics	Admin & Logs Mechanisms	Administrative & Legal Reforms	International Legal Activity

INSURGENT MILITARY CAPABILITIES SHAPING THE EXPEDITIONARY ENVIRONMENT

CAPABILITY	HIGH COMPLEXITY	MEDIUM COMPLEXITY	LOW COMPLEXITY
COMMITMENT TO TERRORISM	Leaders & followers commited to global campaign of terrorism	National program of terrorism against selected targets	Only occasional resort to terrorism as method of ops
CAPABILITY FOR TERRORISM	International support network and freedom of movement	Limited ability to conduct terrorist acts away from home	Limited to local acts of terrorism
SAFE-HAVEN OR CONTROLLED TERRITORY	Multiple controlled areas and/or adjacent countries offering S/H	Mixed rural-urban controlled area &/or single S/H country	Small rural area or no regular control, free night passage
STEADY FLOW OF WEAPONS & TRAINED G'S	Regular deliveries of arms, established training areas	Occasional shipment of arms, foreign & informal training	Sporadic & limited arms deliveries, no regular training
ESTABLISHED MILITARY ORGANIZATION	National military command & regional command structure	Informal coordination among separate regional mil. ldrs.	Popular leaders of small bands or cells with no staff
ACQUISITION OF CREW-SERVED WPNS & VEHICLES	Regular pipeline for introduction of larger wpns & mil. vehicles	Shoulder-held SAMs & heavy MG, Mortars, use commercial veh.	Limited to small arms, grenades; walk & use animals
ESTABLISHED C4I2 NETWORKS	National & regional radio & informant networks w/security	Some mobile radio equipment, crude intelligence nets	Limited to personal & commercial comms, personal obsvtn.

HOST COUNTRY MILITARY CAPABILITIES SHAPING THE EXPEDITIONARY ENVIRONMENT

CAPABILITY	HIGH COMPLEXITY	MEDIUM COMPLEXITY	LOW COMPLEXITY
LEADERSHIP	Opportunistic & corrupt leaders w/o scrupples	Trained officers, no/untrained NCOS, conscripted troops	Highly professional military sensitive to popular concerns
MILITARY INTELLIGENCE	Only informal sources & no standard methods for intel processing	Provincial networks under informal control	Organized networks & data handling techniques
TROOP DISCIPLINE & BEHAVIOR	Conscripted troops of different ethnic or regional origin	Untrained troops inclined to violent repression	Trained disciplined troops sensitive to popular concerns
USE OF POPULAR MILITIA	Marginal militia not integrated into military structure	Organized militia independent of regular military	Organized militia fully integrated into regular struc.
FORCE STRUCTURE	Paramilitary force without counter-insurgency training	Military ground force, limited air, some CI training	Complete combined arms force including SO/CI forces
STRATEGY	Top-level refusal to adopt national civil-military strategy	Limited commitment to partial strategy for CI operations	National political & military commitment to CI strategy
TACTICS	Troop leaders refuse to adopt appropriate tactics (e.g. night)	Some troop leaders experiment with & adopt CI tactics	Full understanding & commitment to CI tactics in military

INSURGENT CIVIL FACTORS SHAPING THE EXPEDITIONARY ENVIRONMENT

CAPABILITY	HIGH COMPLEXITY	MEDIUM COMPLEXITY	LOW COMPLEXITY
OVERT POLITICAL MOBILIZATION	Full range of front organizations & ties, int'l representation	One or more front organizations, some political support	Exist as faction within established pol/labor group
COVERT POLITICAL MOBILIZATION	International covert network for channeling funds & information	National covert network, limited int'l connections	Covert cells in select rural/urban areas
PROPAGANDA	High-profile int'l network able to feed video/print material	Organized media strategy & manning, some production	Staged local events with verbal briefs for media
CIVIL ACQUISITION	Full capability to acquire & distribute equip, clothes, food	One-time or ad hoc procurement of items in bulk	Occasional thefts to obtain specific needed items
FUNDING MECHANISM	Int'l financial net with regular flow of funds from supporters	National protection racket or other stable funding	Occasional thefts or reliance on local contributions
INDOCTRINATION MECHANISM	Established ideology & political/economic program w/training	Populist program w/simplistic goals but no training	No established program or indoctrination
ADMIN & LOGS MECHANISMS	Organized files & property control, accountability	Personal files & oversight, some coordination	Limited or no record keeping & accountability

HOST COUNTRY CI[illegible] ACTORS SHAPING THE EXPEDITIONARY ENVIRONMENT

CAPABILITY	HIGH COMPLEXITY	MEDIUM COMPLEXITY	LOW COMPLEXITY
POLICE OPERATIONS	Personal or para-military police w/o public peace role	Organized police w/limited ability to ensure peace	Integated national police force fully committed to peace
CIVILIAN INTELLIGENCE OPERATIONS	Opportunistic, corrupt, or limited civilian intelligence org.	Urban/rural-based civilian intel with personal networks	National integrated civilian intel with sources & methods
CIVIL-MILITARY RELATIONS	Completely autonomous military independent of civilian control	Working relations btw civil authority & military forces	Military fully subordinate & supportive of civil.
UNIFIED MANAGEMENT	Autonomous or disorganized agencies unable to coord.	Organized military w/police cooperation in some areas	Fully integrated civil-military ops across host country
PSYCHOLOGICAL OPERATIONS	Government unwilling to sponsor PSYOP or lacking in credibility	Limited topic or duration PSYOP if external assist.	Full PSYOP program with quality effort & good media access
POLITICAL ENVIRONMENT	Government does not appeal to populace, lacks legitimacy	Government neutral, military or security forces unpopular	Government and its forces appeal to populace
ADMINISTRATIVE & LEGAL REFORMS	Civil or military refusal to compromise or sponsor reforms	Limited admin & legal reforms w/o full enforcement	Fully enforced reforms w/strong military support

INSURGENT EVENT DATA SHAPING THE EXPEDITIONARY ENVIRONMENT

CAPABILITY	HIGH COMPLEXITY	MEDIUM COMPLEXITY	LOW COMPLEXITY
BOMBINGS	Deliberate & frequent bombings of key infra-structure nodes	Occasional major bombing campaigns throughout country	Random bombings for effect on public & private property
KIDNAPPING & ASSASSINATION	Routine kidnappings for funds & routine assassination of pols.	Occasional kid-napping for effect, selected assassins.	Random kidnappings or assassinations
CIVIL DISOBEDIENCE	Strong labor/school support, large public shows of solidarity	Occasional major demonstrations w/o violence	Infrequent public demonstrations, limited turnouts
STRIKES & RIOTS	Regular strikes & riots paralyzing the economy	Occasional strikes or riots affecting areas or industries	Infrequent strikes or riots limited in scope & duration
INTERNATIONAL MEDIA EVENTS	Daily or weekly events staged for or communi-cated to int'l media	Monthly int'l media events, or advance notice of ops	Occasional local events of limited interest to media
CONVENTIONAL MILITARY OPS	Established campaign of national scope with artillery support	Regional campaign with good C4I2, mortars, SAMS	"Hit & Run" tactics only, reliance on escape vice arms
INTERNATIONAL LEGAL ACTIVITY	Established territory & controlled populace, attempted recognition	Routine appeals to int'l organizations for observer status	No basis for legal recognition, no real attempts

APPENDIX F-2

Mission Area Factors Summary

A. TERMS OF REFERENCE INTRODUCTION

Mission area factors were developed by the Marine Air-Ground Task Force (MAGTF) Integration Section, Proponency and Requirements Branch of the MAGTF Warfighting Center to show the various threats and conditions that may be encountered by warfighters when operating in the countries of the expeditionary environment. The following charts depict the mission area factors and outline the criteria for levels of difficulty (thresholds) within each factor.

MISSION AREA FACTORS: THREAT

MISSION AREA FACTORS THREAT	CRITERIA LEVELS OF DIFFICULTY					
Drugs	Low		Medium			High
Terrorism	Low	Medium -			Medium +	High
Grey Arms/Tech Transfer	Low		Medium			High
Consolidated Threat	Negligible	1 of 3			2 of 3	All 3
General Ground OOB						
Infantry	Draft/No TR	Draft/TR	PM/No Exp	PM	Reg/TR	Reg/Exp
Armor	None	M-48/T-54/LAV	M-60,AA	T-62E/MOD 55	T-72M1	T-80/64B
Artillery	None	Mortars	How/SP	>30K Range/ FASCAM/TGM	>30K Range/NBC	BLOC
General Air OOB						
Air OOB	None	DC-3/Props	Day/VFR Jets	Early Radar	3d Gen Radar	BLOC
Close Air	None	Props	Day Jet Atk	Early Smart	STD-OFF PGM	NT/AW
AAW(IAD)	None	Early AAA	Hand-Held SAMs	EW Radar	3d Gen SAMs	BLOC
General Naval OOB						
Naval OOB	None	Small Surface	DEST/FRIG	ASUW/Air/ASW	F/W Carrier	NT/AW
S/S Msls	None	HE	Multi Warhead HE/BC	High/Flex Trajectories	Countermeasures	BLOC
Patrol Craft	None	Speed Boats	Sm Gun Boats	Lg Gun Boats	ASUW/Amlair	BLOC
NBC	None	Chem Weap/ No Delivery	Chem Weap/ With Delivery	Chem Weap/ Used	Chem/Bio Used	Nuc/Chem Avail
Ongoing Conflicts	No Conflicts					Conflicts

MISSION AREA FACTORS: ENVIRONMENT

MISSION AREA FACTORS ENVIRONMENT	CRITERIA LEVELS OF DIFFICULTY					
U.S. Equities	Low		Medium			High
Culture						
Language	English	Spanish/French		Arabic		All Others
Religion	Christian	Christian Orthodox		Eastern/Tribal/Islam		Islam
Weather	Dry/Warm	Wet/Warm	Mixed	Dry/Hot	Wet/Hot	Wet/Cold
Gen Geo Cond	Urban	Desert		Jungle		Mountainous
OP Elevation	<2000 Ft	<4000 Ft	<6000 Ft	>6000 Ft	>9000 Ft	>12000 Ft
Cross-Country Mob	Generally Suited			Partially Suited		Generally Unsuited
Intervisibility (LOS)	>2000 Meters			1000-2000 Meters		<1000 Meters
Hydrography- NGF	Good	Fair		Poor		Unsatisfactory
Hydrography- Coastal Threat	US NGF Advantage			US NGF and Threat Equal		Threat Advantage

MISSION AREA FACTORS: LOGISTICS

MISSION AREA FACTORS LOGISTICS	CRITERIA LEVELS OF DIFFICULTY					
MC&G Coverage	1:50 New	1:50 Old	Some 1:50	MSI Avail	1:250 New	None
Airfields	>1/C-5	1/C-5	>5/C-130	2-4/C-130	1/C-130	None

* For purposes of this study, 500 evacuees was used as a threshold. Anything above 500 would probably require consideration of other options, i.e., evacuation by airlift or sealift.

These mission area factors define the critical conditions, situations, threats, and logistical constraints which, when taken together with the countries identified, show various levels or thresholds of difficulty for conducting military operations. This product repesents a totally new approach to intelligence for warfighters because it evaluates and classifies countries in relationship to mission area factors and levels of difficulty assigned by warfighters themselves. The mission area factors do not represent a "fixed" list but constitute a "snapshot" based on their initial development in 1989 and 1990. The way in which thresholds between levels of difficulty for each factor are defined can be expected to change over time. Our intent at this stage has been to inform, to provice a useful reference that does not need to be locked up, and to establish and introductory baseline from which more detailed and precise factors and thresholds of difficulty can be developed.

The following charts provide a consolidated overview of seleted mission area factors for those countries which represent the greatest combination of threat, terrain, and logistic challenges to the MAGTF Such countries would be good candidates as models for the testing of USMC scenarios.

B. CRITERIA AND SUMMARY ASSESSMENTS

The following pages will address each of the mission area factors separately and further describe the criteria by which levels of difficulty were established. These discussions will also include a summary assessment (taken from Volume I) of how individual factors impact on the 69 countries which presently comprise the expeditionary environment.

DRUG THREAT

CRITERIA FOR LEVELS OF DIFFICULTY

HIGH:

- Major drug producing and/or processing countries
- Heavy involvement in support functions for drug trafficking.

MEDIUM:

- Minor drug producing and/or processing countries
- Primary involvement is in one or more of the following:
  - Money laundering
  - Drug transshipment
  - Supply of precursor chemicals

LOW

- Drugs are of little significance.

Using this criteria, countries were classified into the three threat categories through research of the data sources. These sources included, but were not limited to the following:

(1) Annual Report of the Organized Crime Drug Enforcement Task Force Program, Fiscal Year 1988

(2) Defense Science Board Summer Study 1987, Detection and Neutralization of Illegal Drugs and Terrorist Devices, October 1987.

(3) U.S. Department of State, Bureau of International Narcotics Control, Strategy Report, March 1989.

SUMMARY ASSESSMENT OF IMPACT ON EXPEDITIONARY ENVIRONMENT COUNTRIES

The "war on drugs" is developing into a real war and **Latin America** in particular offers a "target rich environment" where Marine Corps forces can expect to be on call to assist law enforcement agencies.

In **Asia**, the "**Golden Triangle**" where **Burma, Thailand, and Laos** share a border is the center of the heroin trade, and this area should also see an increase in joint military-law enforcement activity in the future.

The top three drug trafficking countries were consiered to be **Colombia, Peru, and Burma**. Overviews of those countries are as follows:

(1) **Colombia** is the center of **South American** cocaine trafficking, the world's largest producer of marijuana, and the world's third largest producer of coca. This country has destroyed more than 90 percent of the cannabis growing in traditional northern areas, but traffickers have planted extensively in the San Lucas Mountains and south in Cauca. Marijuana tonnage increased in 1988 despite an aggressive eradication campaign. Coca cultivation increased above the 1987 level although eradication of 230 hectares was conducted manually. Despite police efforts to harrass the **Medellin** cartel and other trafficking groups, large amounts of cocaine continued to flow to the U.S.; almost 20 metric tons were seized by U.S. Customs. Overall enforcement remains hampered by a judicial system that has been intimidated by violence. Drug profits flow into and out of **Colombia**, but money laundering per se is not a major activity.

(2) **Peru** is the world's largest producer of coca with between 97,000 to 124,000 metric tons harvested in 1988. In addition, it converts much of its coca into coca paste and is a primary supplier of this substance to Colombian cocaine refineries. Enforcement in the **Upper Huallaga Valley**, the major growing zone for coca remains quite hazardous.

(3) **Burma** is the world's largest producer of opium with between 1,065 to 1,500 metric tons harvested in 1988. Political turmoil in the country has grounded its large-scale aerial eradication program until an effective Government is seated in **Rangoon**. Traffickers capitalized on diminished enforcement efforts to smuggle large quantities of opium and heroin with little interference. The prospect for the future is grim: with highly favorable climatic conditions and the suspension of programs to destroy crops or seize shipments of drugs or precursor chemicals from **China**, **Thailand**, and **India**, traffickers may harvest and move annually as much as 1,400 metric tons of opium to heroin refiners in **Southeast Asia**.

The following matrix shows the expeditionary environment countries that are most involved in drug production and trafficking:

MOST SIGNIFICANT DRUG COUNTRIES TYPES OF THREAT

	DRUG PRODUCTION	DRUG PROCESSING	PRECURSOR CHEMICALS	MONEY LAUNDERING	TRANSIT POINT
WESTERN HEMISPHERE					
ARGENTINA		X	X	X	X
BOLIVIA	X	X			
BRAZIL	X	X	X		X
COLOMBIA	X	X	X		
ECUADOR	X		X		X
JAMAICA	X				X
MEXICO	X				X
PANAMA			X	X	X
PERU	X	X			
MIDDLE EAST					
IRAN	X				X
ASIA					
AFGHANISTAN	X				
BURMA	X				
LAOS	X				
PAKISTAN	X				
THAILAND	X	X	X		

PLANNING AND PROGRAMMING IMPLICATIONS

In fighting the "war on drugs", the most common form of military assistance is expected to be wide-area surveillance and interdiction. This challenge will tax to the utmost Marine Corps reconnaissance, intelligence, and communications assets. The nature of the target being sought, generally a single nondescript platform integrated among many legitimate aircraft or ocean-going vessels, will require development of close working relationships and fast-reaction capabilities responsive to civilian intelligence and law enforcement leads. The requirements for liaison to law enforcement agencies could become as demanding, and as frustrating, as the present requirements for liaison to various remote threater staffs; Command and Control, Communications, Computers, Intelligence, and Interoperability (C4I2) requirements and capabilities will "Make or Break" Marine Corps forces assigned a role in the war on drugs.

TERRORISM THREAT

CRITERIA FOR LEVELS OF DIFFICULTY

HIGH: Countries found to have a significant association with terrorism, either through state-sponsored terrorism, organizational terrorism, or insurgent terrorism, or a combination of the three.

MEDIUM TO HIGH: Countries which have had past association and still maintain a residual involvement in terrorism, but to a lesser degree than high threat countries.

LOW TO MEDIUM: Countries largely characterized by internal revolutionary activity and related incidents where terrorism plays a role.

LOW: Countries with little or no association with terrorism.

Based on this criteria, countries were classified into the four categories through research of the reference material. This included, but was not limited to the following publications:

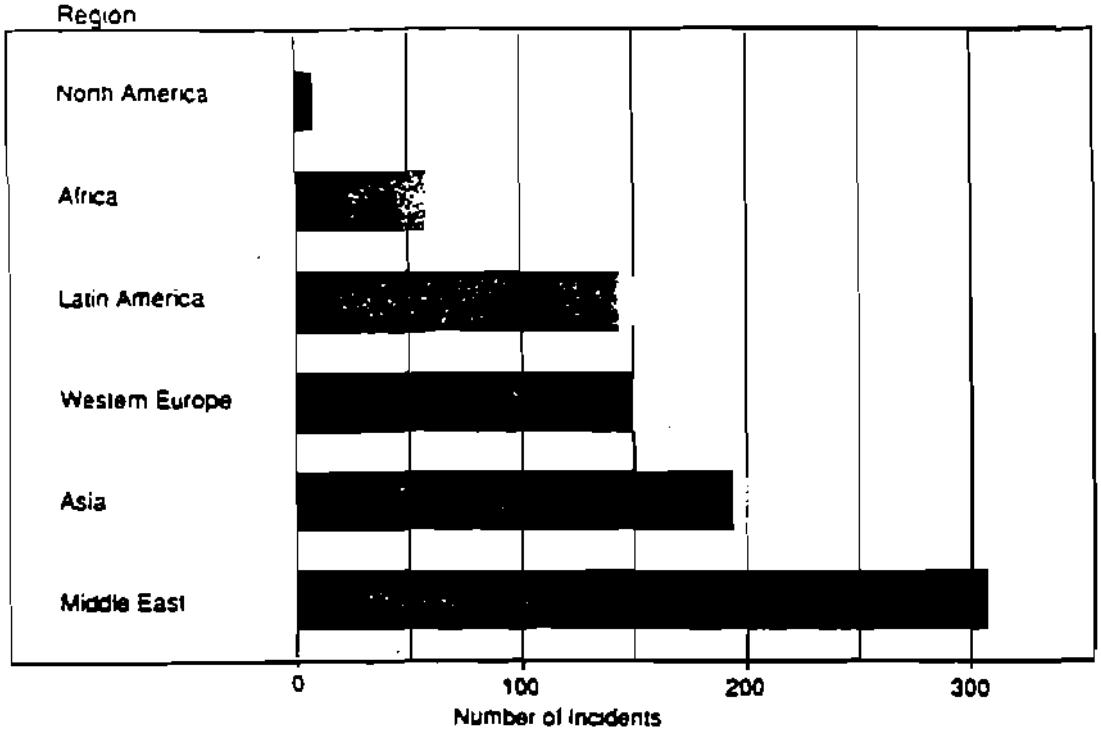
(1) Patterns of Global Terrorism: 1988, Department of State Publication 9705, Office of the Secretary of State Ambassador-at-Large for Counterterrorism, March 1989.

(2) Terrorist Group Profiles, U.S. Government Printing Office, November 1988.

SUMMARY ASSESSMENT OF IMPACT ON EXPEDITIONARY ENVIRONMENT COUNTRIES

The level of international terrorist activity worldwide increased by three percent in 1988 with 856 incidents as compared with 832 in 1987. As shown in the following chart, the **Middle East** continued to be the region most affected, incurring 313 attacks or 36 percent of the total worldwide. When **Middle East** spillover attacks are added, **Middle East**-inspired terrorist incidents account for 41 percent of the total. **Asia**, primarily due to terrorist attacks by **Afghanistan** against targets in **Pakistan**, held second place with 195 incidents or 22 percent of the total.

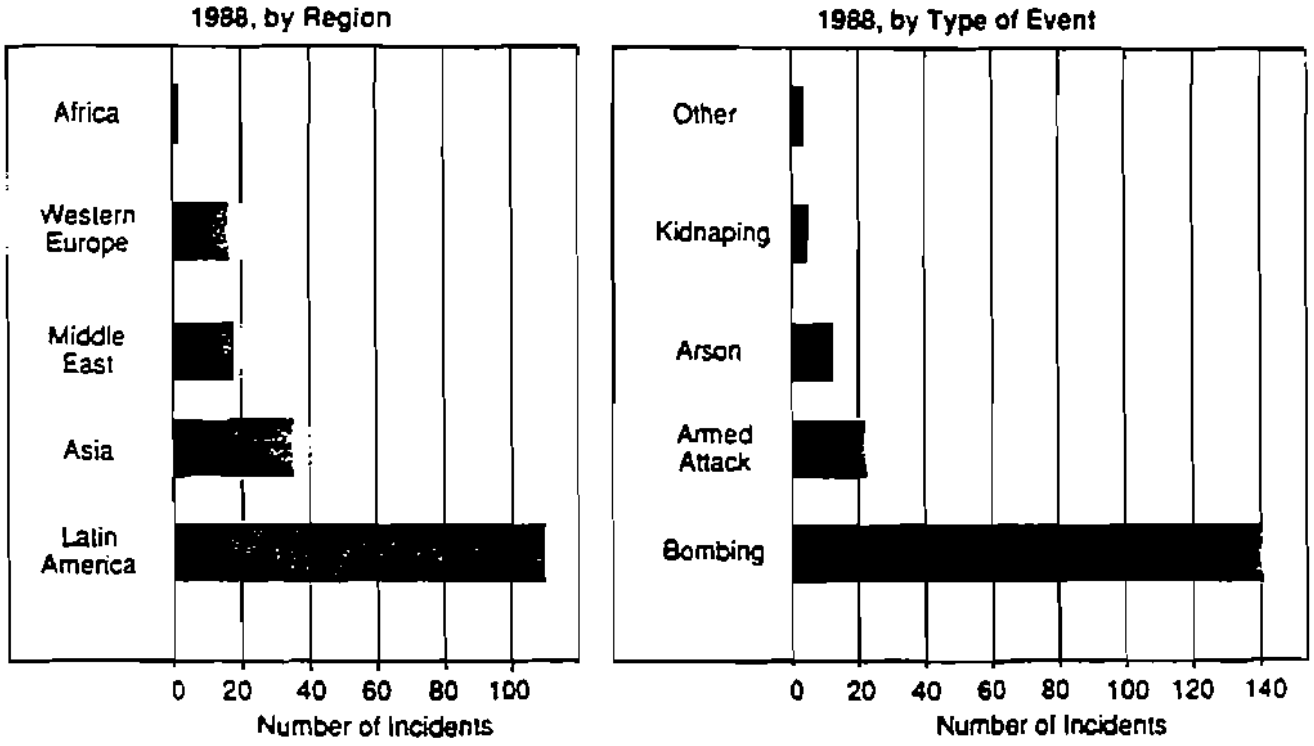
INTERNATIONAL TERRORIST INCIDENTS, 1988



As illustrated in the next two charts, the U.S. sustained a substantial number of attacks and casualties abroad in 1988, indicating that it remains a primary target for international terrorists. The number of anti-U.S. incidents increased in all regions, rising from 149 in 1987 to 185 in 1988, and resulting in 192 persons killed and 49 injured. Latin America was the locus of 60 percent of the incidents against U.S. citizens and property. About 20 percent of the anti-U.S. incidents took place in **Asia** while 10 percent were in the **Middle East** and 9 percent in Western Europe.

In 1988, 48 percent of the terrorist attacks involved bombings. Armed attacks came next with 29 percent followed by arson at 15 percent. Terrorists decreased their use of kidnappings as a method in 1988, with only 4 percent of the total. Of the 32 kidnapping incidents worldwide, 12 took place in Latin America. This was a change from 1987 when most of the kidnappings occurred in the **Middle East**.

ANTI-U.S. TERRORIST ATTACKS



PLANNING AND PROGRAMMING IMPLICATIONS

Terrorism is an unpredictable global threat. **Latin America** is the location of the greatest number of terrorist events, while the **Middle East** contains the greatest numer of terrorist training camps and other targetable facilities. Terrorists do not have rules of engagement, and they generally cannot be detected until after they have struck. MAGTFs must plan for perimeter security measures able to deal with the unexpected. As with drugs, preemptive raids could become more common in the 1990's. Also worth consideration is the possibility of a new method of operation developing between Joint Special Operations Forces (SOFs) and MAGTFs. In concept there is much to be said for the use of SOFs to "find and secure" hostages in place, with MAGTF elements being used to execute a hostile NEO on call. The ability to lift, deliver, and evacuate battalion-sized forces from over-the-horizon and into complex urban environments will be essential for this kind of mission.

GRAY ARMS AND TECHNOLOGY TRANSFER THREAT

CRITERIA FOR LEVELS OF DIFFICULTY

HIGH: Countries found to be sources of gray market arms and technology sales to unstable and potential hostile Third World buyers.

MEDIUM: Countries which have acted as transit sites or transshipment points for gray arms and technology sales.

LOW: Countries with no known association with gray arms and technology transfer.

DEFINITION:

Sales of military and military-related goods that fall between black market sales and open legitimate transactions comprise the gray market. Such grayness originates in the nature of the item being transferred, or in the character of the transaction, or both. In addition to basic weapons transfers, various products fall into the gray zone when they have both civilian and military applications, and if they are being shipped to countries eligible to receive them for civilian but not military use. Computers are good example, as well as communications equipment, unarmed cargo planes, air traffic control radars, and off-road vehicles. A company that ships such equipment to **South Africa** or another embargoed country, knowing it is intended for military use is engaged in gray-market arms trafficking.

Based on this methodology, countries were classified into the three categories through a rigorous review of the source data. Reference material included:

(1) World Military Expenditures and Arms Transfers 1988, U.S. Arms Control and Disarmament Agency

(2) Arms Transfers and the Third World: Trends and Developments, Army-Air Force Center for Low Intensity Conflict, Langley Air Force Base, Virginia, July 1988.

(3) Stockholm International Peace Research Institute (SIPRI) Yearbook 1989, 1988 and 1987

SUMMARY ASSESSMENT OF IMPACT ON EXPEDITIONARY ENVIRONMENT COUNTRIES

The accompanying chart depicts the countries associated with gray arms sales and technology transfer. It is interesting to note that almost 60 percent of the source countries listed are in **Europe** while about 30 percent are in **Asia**

Great Britain, France, Italy, and **West Germany** have proven their technological prowess on the international market. **Japan** has used high technology in home electronics, computers, and semiconductors to gain its current position as an industry leader. **Israel**, has a significant emerging technological capability.

Individuals and companies operating in countries such as **France, Israel,** and **Japan** serve as either sources of arms for the Third World or as conduits through which **China, North Korea, Vietnam, Iran,** and **Iraq** illegally acquire restricted **U.S.** technology. In turn, these countries, as a routine policy, distribute arms and restricted technology to revolutionary groups and terrorists.

During the period 1981 to 1987, 502 individuals and companies were cited in 156 cases arising from violations of the 1976 Arms Export Control Act. However, it is suspected that many of the less visible brokers, financiers, middlemen, and fixers who specialize in convert arms transactions escaped detection.

COUNTRIES INVOLVED IN GRAY ARMS AND TECHNOLOGY TRANSFER

SOURCES	TRANSIT POINTS	BUYERS
BELGIUM	BELGIUM	AFGHANISTAN
CHINA	BULGARIA	ALGERIA
FINLAND	CHINA	ANGOLA
FRANCE	CUBA	BANGLADESH
INDIA	CYPRUS	COLOMBIA
ISRAEL	GREECE	CUBA
ITALY	HONG KONG	IRAN
JAPAN	ITALY	IRAQ
NETHERLANDS	MEXICO	KENYA
NORTH KOREA	NETHERLANDS	LIBYA
PANAMA	PANAMA	MALAYSIA
SCOTLAND	PORTUGAL	NICARAGUA
SWEDEN	SINGAPORE	NORTH KOREA
TURKEY	SOUTH AFRICA	SOMALIA
UNITED KINGDOM	SOUTH YEMEN	SOUTH AFRICA
VIETNAM	SYRIA	SOUTH YEMEN
WEST GERMANY		SUDAN
		UGANDA
		VIETNAM

PLANNING AND PROGRAMMING IMPLICATIONS

The sale of arms and technology to the Third World by more developed nations is of an increasing concern to the U.S. Questionable sales of restricted systems and material to unstable Third World countries are occurring largely through third party transfers. Such transfers often involve at least one Third World transit point. Panama for example, is a major transshipment site for computer technology enroute from the U.S. to Eastern Europe. Included in this threat is the proliferation of nuclear, biological, and chemical weapons and manufacturing capabilities, as well as the marketing of "Blue" (allied) weapons systems which cannot be countered without adverse impact on friendly forces. Many of the industrialized countries of Europe as well as emerging Third World countries are showing growth in arms and technology sales in the international market. While efforts are being made by cooperating countries to prevent illegal or questionable sales, they are frequently unsuccessful. Involved countries may not be aware of impending sales or may disagree with a U.S. view against a sale. Furthermore, U.S. attempts to define and restrict "dual-use" technology are frequently years behind industry development, so that such technologies are usually available during their early production. Finally, some private companies and individuals are willing to violate the laws and sell to any interested party for a profit. Gray arms trafficking and technology theft may generate requirements for the employment of Marine forces to destroy arms factories and storage depots, neutralize terrorist stocks of bio-chemical weapons, or confiscate stolen materials.

CONSOLIDATED THREAT OVERVIEW

CRITERIA FOR LEVELS OF DIFFICULTY

The most difficult countries are in the "all 3" category which indicates involvement with drugs, terrorism, and gray arms/technology transfer. Progressively lower levels of difficulty are shown by country involvement in "2 of 3", "1 of 3" or "negligible" association with these threats.

SUMMARY ASSESSMENT OF IMPACT ON EXPEDITIONARY ENVIRONMENT COUNTRIES

The accompanying matrices show the involvement of expeditionary environment countries in the three threat areas of drugs, terrorism, and gray arms/technology transfers. In the **Western Hemisphere, Cuba, Mexico, and Panama** were the high-threat countries with involvement in all three areas. Eight other countries, or 50 percent of the countries addressed in this region, were associated with both drugs and terrorism.

In the **Middle East/Southwest Asia, Syria** was the highest threat country, followed by **Iran, Lebanon, South Yemen, Egypt, and Libya.**

Africa was the lowest overall threat. Only **Angola, Kenya, and South Africa** were identified with one threat area.

In **Asia, India** presented the greatest threat with involvement in all areas, while six other countries were identified with two of three areas and six countries with one of three areas.

In **Europe/Mediterranean, Greece** and **Turkey** were both high-threat countries followed by **Italy** with involvement in terrorism and gray arms/technology transfer.

PLANNING AND PROGRAMMING IMPLICATIONS

Drug trafficking, terrorism, and gray arms trade are likely to be national security issues in the next decade. MAGTFs, operating as integral components of the balanced fleet, may have to respond to crisis situations in a variety of ways to protect the national interest. These may range from providing security or peacekeeping forces to conducting retaliatory strikes against threat forces. Marines must continually evaluate the threat as well as their operational concepts, doctrine, force structure, and acquisitions to ensure the maximum preparedness for potential contingency operations. Drugs, terrorism, and gray arms "targets" and scenarios require a different force structure, different organization and equipment, and different concepts and capabilities in C4I2. Force planners must also focus on the unique challenges of Third World environments and logistics requirements where Marine forces must operate without being able to turn on the conventional warfare "pipeline."

GENERAL GROUND ORDER OF BATTLE

CRITERIA FOR LEVELS OF DIFFICULTY

General Ground OOB	LEVELS OF DIFFICULTY (CAPABILITY) →					
	A	B	C	D	E	F
Infantry	Draft/No TR	Draft/TR	PMN/No Exp	PM	Reg/TR	Reg/Exp
Armor	None	M-48/T-54/LAV	M-60, AA	T-62/MOD 55	T-72M1	T-80/64B
Artillery	None	Mortars	How/SP	>30 Range/ FASCAM/TGM	>30 Range/NBC	BLOC

The expeditionary environment countries were broken into six approximately equal groups based on an assigned total capability value. The groups ranged from "A" with the least general ground Order of Battle (OOB) capability to "F" with the greatest. The total capability value was obtained by assigning points to the various infantry, armor and artillery capabilities, with the most significant capabilities (e.g., Reg/Exp, T-80/64B, BLOC) receiving the most points. Army size and quality (an assessment of training, leadership, combat experience, and general efficiency) were also factored into the total capability value. Volume II, Study Supporting Material, Section 13, General Gound Order of Battle contains more detailed information on this process including the exact point values assigned and the calculations made for each country. The references used as source material for this assessment are as follows:

(1) The Military Balance, 1988 - 1989
(2) Defense and Foreign Affairs Handbook, 1989
(3) World Armies, Second Edition by John Keegan, 1983

SUMMARY ASSESSMENT OF IMPACT ON EXPEDITIONARY ENVIRONMENT COUNTRIES

The accompanying matrices show the general ground OOB capabilities for expeditionary environment countries. Most countries in the **Western Hemisphere** had either small or small-to-medium capabilites. The countries with the most significant resources were **Cuba, Nicaragua, Colombia,** and **Mexico**.

In the **Middle East/Southwest Asia**, the countries which stood out with the largest capabilities were Egypt, Iran, Iraq, Syria, Libya, and **Saudi Arabia**.

GENERAL GROUND OOB CAPABILTIES

INCREASING CAPABILITY →

WESTERN HEMISPHERE	COSTA RICA	DOM. REP	EL SALVADOR	COLOMBIA	CUBA	
	GRENADA	HAITI	GUATEMALA	MEXICO	NICARAGUA

	SURINAM					
MIDDLE EAST/ SOUTHWEST ASIA	KUWAIT	BAHRAIN	LEBANON	SAUDI ARABIA	LIBYA	EGYPT
		QATAR	NORTH YEMEN			IRAN
			OMAN			IRAQ
			SOUTH YEMEN			SYRIA
			UAE			

The most impressive ground OOB capabilities in **Africa** were found in the countries of **Algeria** and **Ethiopia**, followed by **Angola, Somalia, South Africa, Sudan and Uganda.**

In **Asia**, the countries of **India, North Korea, the Peoples' Republic of China**, and **Vietnam** were identified to have the largest capabilities not only in the region, but in the entire expeditionary environment. They were followed by **Pakistan, South Korea, Burma, Indonesia, Japan**, and **Thailand.**

In **Europe, Turkey** had the largest ground OOB followed by **Greece, Italy**, and **Yugoslavia.**

					YUGOSLAVIA	

PLANNING AND PROGRAMMING IMPLICATIONS

Besides Soviet proxies with advanced weapons systems, the conventional threat includes Third World countries using non-Soviet systems sold to them by allied or nominally friendly countries, and relatively sophisticated systems developed by Third World regional powers. The non-Soviet systems complicate our electronic warfare planning, signal intelligence, and communications; for in some instances we cannot jam them without jamming ourselves, and because of shared frequency spectrums.

The expeditionary environment is complex and lethal. The MAGTF can expect to meet trained and experienced infantry, modern armor, relatively sophisticated artillery including scatterable mines, as well as smart or stand-off munitions. Some countries have sophisticated surface-to-surface missiles and other advanced coastal defense systems.

An overview assessment of capabilities indicates that a MEU could conduct successful operations in countries with a small ground OOB. Depending on intelligence and threat country force dispostions, a MEU could also conduct successful raid-type operations against the larger and stronger countries. Such missions as Noncombatant Evacuation Operations (NEO) and other limited objective operations could be conducted with a reasonable chance of success provided there was adequate preparation and naval support. In deciding how to train, equip, and organize Marine Corps forces our planners much constantly evaluate trade-offs between our own capabilities limited by our forward deployed amphibious character and the small size of our forces afloat, and the fully equipped, trained, and generally well organized forces we might confront.

GENERAL AIR ORDER OF BATTLE

CRITERIA FOR LEVELS OF DIFFICULTY

	LEVELS OF DIFFICULTY (CAPABILITY) →					
	A	B	C	D	E	F
General Air OOB						
Air OOB	None	DC-3/Props	Day/VFR Jets	Early Radar	3d Gen Radar	BLOC
Close Air	None	Props	Day Jet Atk	Early Smart	STD-OFF PGM	NT/AW
AAW (IAD)	None	Early AAA	Hand-Held SAMs	EW Radar	3d Gen SAMs	BLOC

The expeditionary environment countries were divided into six approximately equal groups based on an assigned total capability value. The groups ranged from "A" with the least general air OOB capability to "F" with the greatest. The total capability value was obtained by assigning points to the various air OOB, close air support, and Antiair Warfare (AAW)/Integrated Air Defense (IAD) capabilities, with the most significant capabilities (e.g., BLOC, 3d generation radar, Night Time/All Weather (NT/AW), Stand-Off-Precision Guided Munitions (STD-OFF PGM), 3d generation Surface-to-Air Missiles (SAMs)) receiving the most points. Air Force size and quality (an assessment of training, leadership, combat experience, and general efficiency) were also factored into the total capability value. Volume II, Study Supporting Material, Section 14, General Air Order of Battle contains more detailed information on this process including the exact point values assigned and the calculations made for each country. The references used as source material for this assessment are as follows:

(1) Defense and Foreign Affairs Handbook, 1989
(2) Jane's All the World's Aircraft, 1988 - 1989
(3) Jane's Land Based Air Defense Systems, 1989 - 1990
(4) Jane's Weapon Systems, 1988 - 1989
(5) Jane's Weapon Systems 1987 - 1988

SUMMARY ASSESSMENT OF IMPACT ON EXPEDITIONARY ENVIRONMENT COUNTRIES

The accompanying matrices depict the general air OOB capabilities for expeditionary environment countries. Most countries in the **Western Hemisphere** are grouped in the lowest three categories. In this region, the countries with the most significant aviation resources were **Cuba, Nicaragua, and Peru.**

From a global perspective, **Egypt, Iran, Iraq, and Syria** stood out with the strongest aviation and air defense assets. Other countries in the **Middle East/Southwest Asia** with large capabilities were **Libya, Saudi Arabia, and South Yemen.**

GENERAL AIR OOB CAPABILITIES

INCREASING CAPABILITIES →

WESTERN HEMISPHERE	COSTA RICA	DOM REP	COLOMBIA	NICARAGUA	CUBA	
	GRENADA	GUATEMALA	EL SALVADOR	PERU

						YUGOSLAVIA

PLANNING AND PROGRAMMING IMPLICATIONS

The expeditionary environment in the air is as complex and lethal as that on the ground. The MAGTF can expect to encounter threat aircraft with some night or all-weather capability, as well as smart or stand-off munitions. Iraq, for example, employs MiG-29 aircraft which are kept operationally ready through the assistance of on-site Soviet advisors. Threat integrated air defense systems may include three dimensional long-range radars able to detect stealthy airborne platforms. In this regard, Libya employs an air defense system known as "SENEZH" which is modeled after Soviet equipment and doctrine. China has a relatively sophisticated network of air defense radars which provides surveillance and control, and an early warning system for the detection of hostile missiles. Threat air defense systems may also employ a variety of advanced and strategicallly placed SAMs. Syria, for example, has some of the most modern Soviet provided SAMs as well as 50,000 personnel in a separate air defense command.

An examination of aviation and air defense capabilities of expeditionary environment countries indicates that a MEU could expect to conduct successful air operations against most lower capability countries. Depending on a variety of factors, such as the operational condition of threat aircraft and air defense weapons, unit locations, and detection capabilities, a MEU could also conduct operations effectively against many of the stronger countries. Given our critical reliance on vertical lift as a primary means of expeditionary mobility, Marine Corps planners must make more provision for the suppression of air defense, survivability of lift aircraft, and availability of close air support for all MAGTF missions with special emphasis on stability operations and low-intensity conflict requirements.

GENERAL NAVAL ORDER OF BATTLE

CRITERIA FOR LEVELS OF DIFFICULTY

	LEVELS OF DIFFICULTY (CAPABILITY) →					
	A	B	C	D	E	F
General Naval OOB						
Naval OOB	None	Small Surface	DEST/FRIG	ASUW/Air/ASW	F/W Carrier	NT/AW
S/S Msls	None	ME	Multi Warhead ME/BC	High/Flex Trajectories	Countermeasures	BLOC
Patrol Craft	None	Speedy Boats	Sm Gun Boats	Lg Gun Boats	ASUW/Antiair	BLOC

The expeditionary environment countries were divided into six approximately equal groups based on an assigned total capability value. The groups ranged from "A" with the least general naval OOB capability to "F" with the greatest. The total capability value was obtained by assigning points to the various naval OOB, surface-to-surface missile, and patrol craft capabilities, with the most significant capabilities (e.g., NT/AW, Fixed Wing Carrier, Bloc, Countermeasures, Antisurface Warfare (ASUW)/Antiair) receiving the most points. The Navy size and quality (an assessment of training, leadership, combat experience, and general efficiency) were also factored into the total capability value. Volume II, Study Supporting Material , Section 15, General Naval Order of Battle contains more detailed information on this process including the exact point values assigned and the calculations made for each country. The references used as source material for this assessment are as follows:

(1) Jane's Fighting Ships, 1988 - 1989
(2) Jane's Weapon Systems, 1987 - 1988
(3) Defense and Foreign Affairs Handbook 1989
(4) A Quick and Dirty Guide to War by James Dunnigan and Austin Bay, Updated Edition, dated 1986

SUMMARY ASSESSMENT OF IMPACT ON EXPEDITIONARY ENVIRONMENT COUNTRIES

The accompanying matrices show the general naval OOB capabilities for expeditionary environment countries. In the **Western Hemisphere, Cuba** was identified as having the greatest naval capability, followed by **Colombia, Mexico, Peru,** and **Venezuela.**

In the **Middle East/Southwest Asia, Egypt** stood out with the most well-equipped naval force followed by **Iran, Iraq, Libya,** and **Syria.**

GENERAL NAVAL OOB CAPABILITIES

INCREASING CAPABILITIES →

WESTERN HEMISPHERE	GRENADA	COSTA RICA	DOM REP	COLOMBIA	CUBA	
	SURINAM	GUATEMALA	EL SALVADOR	MEXICO		
		HAITI	NICARAGUA	PERU

			KUWAIT	SOUTH YEMEN	IRAQ	
			NORTH YEMEN		LIBYA	
			OMAN		SYRIA	
			QATAR			
			UAE			

In **Africa** the primary naval forces were found in **Algeria, Ethiopia,** and **South Africa** followed by **Angola, Kenya,** and **Somalia.**

Both **Asia/Pacific** and **Europe Mediterranean** have a high proportion of countries with a strong naval force. In **Asia,** the countries of **India, Indonesia, Japan, North Korea, Pakistan,** the **People's Republic** of China, and **South Korea** were predominate, while in **Europe, Italy, Turkey** and **Yugoslavia** had the most extensive capabilities.

PLANNING AND PROGRAMMING IMPLICATIONS

The expeditionary environment at sea could present some serious challenges for an Amphibious Task Force (ATF) enroute to, or operating in an objective area. India, for example has two fixed wing aircraft carriers (Ex -U.K.), five destroyers, twenty-one frigates, and six corvettes equipped with Surface-toSurface Missiles (SSMs), SAMs, guns, torpedos, antisubmarine mortars, countermeasures, and radars. Another example of an expeditionery environment country with a strong naval capability is Italy. It has two light aircraft carriers (one can accommodate VSTOL aircraft and helicopters, and one can handle helicopters only), two cruisers, six destroyers, sixteen frigates, and nineteen corvettes all equipped with modern weapons and supporting systems.

A review of the naval capabilities of expeditionary environment countries indicates that those countries depicted in the three most difficult categories would represent a formidable threat to a MEU-sized ATF. Limited objective operations in these countries should be planned to take greatest advantage of intelligence, naval support, and the element of surprise. Marine Corps planners should also pursue continued close coordination with the Navy to focus on the shortfalls in amphibious lift, shallow-water anti-submarine and mine warfare, over-the-horizon delivery, and the suppresion of coastal missiles.

NUCLEAR, BIOLOGICAL, AND CHEMICAL ORDER OF BATTLE

CRITERIA FOR LEVELS OF DIFFICULTY

	LEVELS OF DIFFICULTY (CAPABILITY) →					
	A	B	C	D	E	F
NBC	None	Chem/Weap/ No Delivery	Chem Weap With Delivery	Chem Weap/ Used	Chem/Bio Used	Nuc/Chem Avail

E - Countries possessing nuclear and chemical weapons

E - Countries which have used chemical and biological weapons

D - Countries which have used chemical weapons

C - Countries suspected to have chemical weapons with a delivery capability

B - Countries suspected to have chemical weapons but without a means of delivery

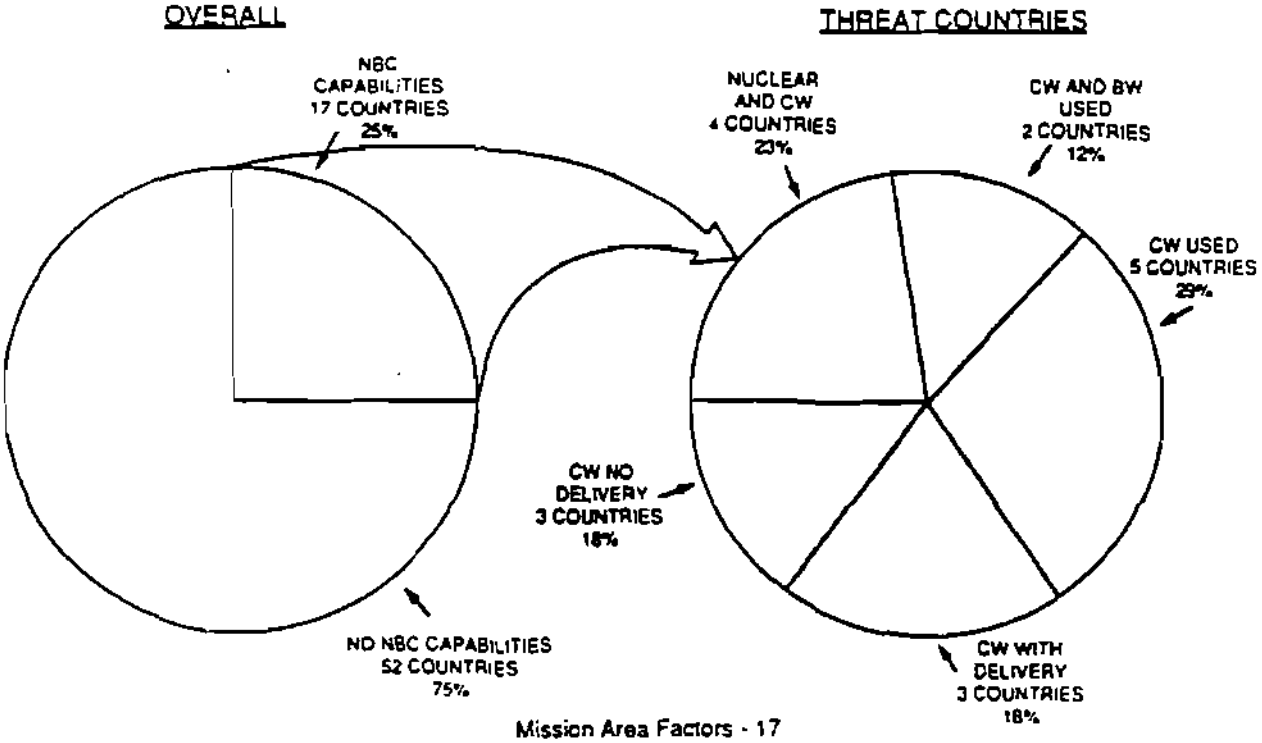
A - Countries believed not to have an NBC weapons capability

Countries in the various categories were identified through a thorough review of open source literature. References most useful to this assessment were the SIPRI Yearbooks, 1989, 1988, and 1987.

SUMMARY ASSESSMENT OF IMPACT ON EXPEDITIONARY ENVIRONMENT COUNTRIES

The accompanying graphics address the expeditionary environment countries which were found to possess varying types and quantities of NBC weapons.

DISTRIBUTION OF EXPEDITIONARY ENVIRONMENT COUNTRIES BASED ON NBC CAPABILITIES



Mission Area Factors - 17

There were 4 countries, (**South Africa, India, Pakistan,** and the **PRC**) thought to possess nuclear and chemical weapons and constitute the greatest threat.

At the next level of threat, there were 2 countries, **Iraq** and **Vietnam**, accused of using both chemical and biological weapons.

Next, there were 5 countries reported to have used chemical weapons only. These countries are **Cuba, Iran, Libya, Indonesia,** and **Thailand.**

The last two categories of threat were the countries with chemical weapons and delivery means, and those with chemical weapons but without a reported means of delivery. Each of these categories had 3 countries. **Egypt, Syria,** and **North Korea** were reported to have chemical weapons with delivery means while **Burma, Japan,** and **South Korea** were thought to have only possession.

NBC THREAT OVERVIEW

	CHEMICAL WEAPONS NO DELIVERY	CHEMICAL WEAPONS WITH DELIVERY	CHEMICAL WEAPONS USED	CHEMICAL WEAPONS AND BIOLOGICAL WEAPONS USED	NUCLEAR AND CHEMICAL WEAPONS
WESTERN HEMISPHERE			CUBA		
MIDDLE EAST/ SOUTHWEST ASIA		EGYPT	IRAN	IRAQ	
		SYRIA	LIBYA		
AFRICA					SOUTH AFRICA
ASIA/PACIFIC	BURMA	NORTH KOREA	INDONESIA	VIETNAM	INDIA
	JAPAN		THAILAND		PAKISTAN
	SOUTH KOREA				PRC

PLANNING AND PROGRAMMING IMPLICATIONS

The NBC threat must be factored into Service capabilities planning and programming. There are countries, particularly in the **Middle East** and **Asia**, that have used bio-chemical weapons and can be expected to use them again. There are increasing numbers of countries that have stocks of bio-chemical weapons, and other countries working to maintain or develop nuclear capabilities. Perhaps most threatening, as NBC technology and weapons proliferate, the opportunities for nongovernmental groups to steal working weapons and active bio-chemical agents increases dramatically. The next decade may well see a large metropolitan area held hostage to the threat of covertly emplaced and remotely detonated bio-chemical or nuclear weapons.

Some MAGTFs, for example those assigned contingency missions in the **Middle East** and selected countries in **Asia**, must continue to plan for and stock equipment needed to fight in a contaminated environment. All MAGTFs should be prepared to execute raids to seize and neutralize NBC weapons under development or in transit.

However, it would be imprudent to over-emphasize this threat, which appears in only 25% of the countries of concern to the Marine Corps. One strategy of possible value would be to carefully tailor a single MAGTF and develop MEU (NBC) training and equipping cycles just as we have for MEU (SOC).

ONGOING CONFLICTS

CRITERIA FOR LEVELS OF DIFFICULTY

Through a review of the source material, conflicts locations throughout the world were identified. These conflicts fell into five categories: regional conflicts, civil wars, insurgencies, drug related conflicts, and conflicts involving government instability and repression. In many of the situations, various levels of violence and disorder have occurred in the past and threaten to break out again. In other cases fighting occurs continuously or intermittently at the present time. All countries were evaluated for their involvement in conflict situations. Volume II, Study Supporting Material, Section 5, Existing Ongoing Conflicts provides a description of ongoing conflicts in the countries of interest. When research identified conflicts in countries outside the expeditionary environment, they were also described. The following references were used as the principal basis for this assessment:

(1) Defense and Foreign Affairs Handbook, 1989
(2) A Quick and Dirty Guide to War, by James F. Dunnigan and Austin Bay, 1986
(3) The Statesman's Yearbook, 1989 - 1990
(4) World Almanac and Book of Facts, 1989
(5) Zones of Conflict: An Atlas of Future Wars, by John Keagan and Andrew Wheatcraft, 1988
(6) Countries of the World and Their Leaders Yearbook, 1989
(7) The World in Conflict, by John Laffin, 1989
(8) Brassey's War Annual 2, A Guide to Contemporary Wars and Conflicts, by John Laffin, 1986

SUMMARY ASSESSMENT OF IMPACT ON EXPEDITIONARY ENVIRONMENT COUNTRIES

The accompanying chart shows a regional breakdown of conflict locations and the types of conflict involved. In the **Western Hemisphere** there have been various levels of violence and disorder in **El Salvador, Guatemala, Honduras,** and **Nicaragua** caused by insurgents. Drug related violence, often combined with terrorism and insurgency, is a major problem in **Colombia** and **Peru.**

In the **Middle East,** regional disputes have prevailed in recent years dominated largely by the **Iran-Iraq** War and **Syrian** intervention in **Lebanon. Syria** would like to take advantage of the civil war in **Lebanon** to expand its borders. The territorial issue between **Israel** and the Palistinians is also highly volitile and the possibility of escalated conflict is a major concern. Now, a new confrontation in this region has erupted between **Iraq** and its Arab neighbors, as well as the **U.S.** and most other countries of the world, over the **Iraqi** seizure of **Kuwait.** Only **Libya,** the Palestine Liberation Organization (PLO), and to a certain degree **Jordan** and **Sudan** seem to side with **Iraq.** This confrontation has potential to be the largest conflict in recent years.

In **Africa,** there are a range of conflicts from the civil wars in **Angola, Liberia** and **Mozambique,** to the insurgent violence in **Ethiopia,** to the disorder and bloodshed in **South Africa** over apartheid. In this region, many countries can be characterized by government instability, frequent violence, economic underdevelopment, and acute poverty. The crisis-torn west **African** country of **Liberia** is an example of an ongoing conflict with poor prospects for resolution in the immediate future. To protect **U.S.** interests, a **MEU** was recently committed in this country to conduct noncombatant evacuation operations and maintain order around the **U.S.** Embassy. In **Ethiopia,** civil war and starvation continue to prevail, while a corrupt and unstable Marxist regime struggles to remain in power. As the **South African** Government continues to support its policy of apartheid and black **African** groups fight among themselves, there is potential for serious consequences in this country.

In **Asia** and the **Pacific,** a major share of the 12 conflicts countries are involved in insurgencies and/or drug related violence. Countries such as **Afghanistan, Cambodia,** and the **Philippines** all have active guerrilla forces trying to overthrow their governments. The "Golden Triangle" where **Burma, Thailand,** and **Laos** share a border, is the center of the region's heroin trade as well as frequent clashes between drug traffickers and government authorities. Countries such as **North Korea** have stocks of chemical weapons, and other countries (**PRC, India,** and **Pakistan**) are working to expand an already developed arsenal of nuclear weapons. Given the rate at which NBC weapons are proliferating in this region, it is quite likely they will eventually fall into the hands of extremist or terrorist groups.

While **Europe** and the **Mediterranean** presently have no active conflicts, there is significant ethnic unrest along with political and economic turmoil in a number of countries that could form the basis for open conflict. Although Poland now has free elections and a non-Communist government, severe economic problems persist and there could be a resurgence of hostility from the people if conditions do not rapidly improve. The longstanding disputes between **Greece** and **Turkey** could easily reemerge as they did in 1987. If this should occur over an issue such as the oil rights under the Aegean Sea, it could lead to a war between these two countries which would have serious impact on **Europe** as well as the **U.S.**

CONFLICTS LOCATIONS

KEY: R- REGIONAL CW - CIVIL WAR I - INSURGENCY D - DRUGS I/R - INSTABILITY/REPRESSION

PLANNING AND PROGRAMMING IMPLICATIONS

The expeditionary environment is a violent one with numerous existing conflicts and high likelihood of increased instability in the future. The emerging threat of the 1990's is predominantly nongovernmental, nonconventional, dynamic or random, nonlinear, and without rules of engagement or known doctrine. This threat is also difficult to guard against because our national intelligence community does not have an "indications and warnings" capability against these "type"threats, while the emerging enemy, by contrast, has a virtually unlimited source of drug addicts and related criminals that can be mobilized to compromise our own operational security. The emerging threat has added "worst case" scenarios for which MAGTFs must prepare, including the threat of nonconventional attacks, such as bio-chemical attacks against concentrations of U.S. citizens overseas. In view of the diversity of threats it may confront in the future, MAGTFs must train, equip, and organize to be prepared for operations across the spectrum of conflict, while being more thoughtful about what specific roles and missions a single MAGTF can realistically undertake by itself and/or as the vanguard of follow-on forces.

U.S. EQUITIES OVERSEAS

CRITERIA FOR LEVELS OF DIFFICULTY

HIGH - Countries with substantial U.S. equities.

MEDIUM - Countries with moderate U.S. equities.

LOW - Countries with few U.S. equities.

For purposes of this assessment, U.S. equities in the countries of interest included:

- Direct investment
- Trade (imports and exports)
- Economic and military aid
- U.S. citizens in residence
- Strategic and tactical equities (e.g., strategic location, U.S. bases, special cooperation)

In the process of determining overall U.S. equities, the following two step methodology was used:

(1) The monetary values of U.S. direct investment, exports, imports, and U.S. aid for each country were combined and applied to the U.S. $ Equities scale below. The number of U.S. citizens living in each country was applied to the U.S. Citizen Equity scale:

U.S. $ EQUITY	
BIL $S	RATING
>10.00	6
5.00 - 10.00	5
2.50 - 4.99	4
1.00 - 2.49	3
.50 - .99	2
>0 - .49	1
0	0

U.S. CITIZEN EQUITY	
NO. CIT.	RATING
>10,000	6
5,000 - 10,000	5
2,500 - 4,999	4
1,000 - 2,499	3
500 - 999	2
>0 - 499	1
0	0

(2) The U.S. dollar equity rating and U.S. citizen equity rating were added together and applied to the following overall U.S. equity scale:

OVERALL U.S. EQUITY		
HIGH	-	9-12
MEDIUM	-	5-8
LOW	-	0-4

Volume II, Study Supporting Material, Section 6, U.S. Equities Overseas contains a description of strategic and tactical equities in the respective countries as well as the data for U.S. military and citizen equities on which the ratings were based. The following references were used as source material for this assessment:

(1) U.S. Department of State, Country Reports on Economic Policy and Trade Practices, 1989
(2) Defense and Foreign Affairs Handbook, 1989
(3) Countries of the World and Their Leaders Yearbook 1989, Gale Research, Inc.
(4) Central Intelligence Agency, The World Factbook, 1988
(5) U.S. Department of State, Background Notes and Post Reports, 1987 - 1989.
(6) U.S. Department of Commerce, Statistical Abstract, 1989.
(7) Consular Affairs Office, U.S. Department of State, Numbers of U.S.Citizens Living in Countries of Interest, 21 - 22 February 1990

SUMMARY ASSESSMENT OF IMPACT ON EXPEDITIONARY ENVIRONMENT COUNTRIES

The accompanying chart shows a regional distribution of countries by their level of U.S. equity. In the **Western Hemisphere, Mexico** had the highest ranking with significantly more dollar equity (25.9 billion) and U.S. citizens (322,250) than other countries. It was followed by **Venezuela, Panama** and **Colombia**, all with over 5 billion in trade and investment, and over 11,000 U.S. citizens. Overall in this region, just under half the countries (7 of 16) fell into the high category while the remainder were about evenly distributed between medium and low.

In the **Middle East/Southwest Asia, Saudi Arabia** had by far the largest U.S. equity with over 10 billion in dollar value and 21,600 U.S. citizens. It was followed by **Egypt** (3 billion dollar equity and 11,210 U.S. citizens). The other countries in this region fell into the low category except for **Kuwait** and **North Yemen** which were rated as medium.

In **Africa**, two thirds of the countries (10 of 15) were rated in the low category. **Algeria, Kenya, Liberia**, and **Zaire** were classified medium and only **South Africa** with 3.5 billion dollar equity and 9,400 U.S. citizens was rated high.

In **Asia/Pacific** region, **Japan** surpassed all other countries with almost 122 billion in dollar equity and 41,000 U.S. citizens. The next closest countries in the high rating were **South Korea** (27 billion dollars and 10,250 U.S. citizens) and the **Philippines** (6 billion and 120,090 U.S. citizens). Besides the 6 countries in the high category, 4 countries including **India** and **Pakistan** were rated medium, and the remainder were low.

In **Europe** and the **Mediterranean, Italy** had the highest rating with 25.6 billion in dollar equity and 92,269 U.S. citizens. It was followed by **Greece** and **Norway** in the high category. The remaining three countries, **Turkey, Denmark** and **Yugoslavia** received a medium classification.

U.S. EQUITY OVERSEAS

	LOW	MEDIUM	HIGH
WESTERN HEMISPHERE	CUBA EL SALVADOR GRENADA NICARAGUA SURINAM	GUATEMALA HAITI HONDURAS JAMAICA	COLOMBIA COSTA RICA DOM REP MEXICO PANAMA PERU VENEZUELA
MIDDLE EAST/ SOUTHWEST ASIA	BAHRAIN IRAN IRAQ LEBANON LIBYA OMAN SOUTH YEMEN SYRIA	KUWAIT NORTH YEMEN	EGYPT SAUDI ARABIA UAE
AFRICA	ANGOLA DJIBOUTI ETHIOPIA MADAGASCAR NAMIBIA SOMALIA SUDAN TUNISIA UGANDA ZIMBABWE	ALGERIA KENYA LIBERIA ZAIRE	SOUTH AFRICA
ASIA/PACIFIC	AFGHANISTAN BANGLADESH BURMA NORTH KOREA SOUTH PACIFIC IS SPRATLY IS SRI LANKA VIETNAM	INDIA MALAYSIA PAKISTAN PAPUA NEW GUINEA	INDONESIA JAPAN PHILIPPINES PRC SOUTH KOREA THAILAND
EUROPE/MED		DENMARK TURKEY YUGOSLAVIA	GREECE ITALY NORWAY

PLANNING AND PROGRAMMING IMPLICATIONS

With existing conflicts in the expeditionary environment and high likelihood of increased instability in the future, U.S. investments and U.S. citizens no longer enjoy the relative immunity from local violence which characterized earlier decades. The increasing lethality of both Third World governments and nonconventional groups places at risk assets and strategic choke points that in the past could only have been attacked by a major power. The deliberate sinking of a major U.S. vessel in both the Panama Canal and Suez Canal is a threat difficult to defend against. As such threats begin to concern policy-makers, the prospects for the employment of U.S. forces in preemptive attacks will increase. To effectively meet the difficult challenges of the future, Marines must sharpen their abilities for rapid crisis-action planning and be ready to "fight smart" when the time comes to execute a mission.

CULTURAL FACTORS: LANGUAGE AND RELIGION

CRITERIA FOR LEVELS OF DIFFICULTY

Cultral	LEVELS OF DIFFICULTY →			
	A	B	C	D
Language	English	Spanish/French	Arabic	All Others
Religion	Christian	Christian Orthodox	Eastern/Tribal/Islam	Islam

D - Countries with hard languages other than those specified below combined with the religion of Islam.

C - Countries with the Arabic language combined with Eastern, Tribal, or Islamic religions

B - Countries with Spanish, French, and other predominately **European** languages combined with the Christian Orthodox religion

A - Countries with the English language combined with the Christian religion

Note - In cases where a country did not match a precise level as specified above, an intermediary level between the language and religion was selected, e.g. **Liberia** with the English language and traditional religion was rated B.

Volume II, Study Supporting Material, Section 17, Cultural Factors: Language and Religion provides tables showing a cultural factors assessment for each country as well as a listing of religions and primary and secondary languages. The references used as source material for this assessment are as follows:

(1) Special Assistant, USMC Intelligence Center letter 3811 IN 06 of 26 October 1989, Marine Corps Expeditionary Environment Language Requirements
(2) Countries of the World, 1989, Gale Research Inc.,
(3) World Almanac and Book of Facts, 1989, Published by Pharos Books, a Scripps Howard Company

SUMMARY ASSESSMENT OF IMPACT ON EXPEDITIONARY ENVIRONMENT COUNTRIES

The accompanying charts depict the distribution of 69 expeditionary environment countries by culture: language and religion. Almost 60 percent of the countries fall into the two most difficult cultural categories (C and D).

The regions with the hardest languages and the most distant religions were the **Middle East/Southwest Asia** (Iran most difficult), **Africa** (**Ethiopia** and **Somalia** most difficult), and **Asia/Pacific** (**Afghanistan, Bangladesh, Indonesia,** and **Pakistan** most difficult). The **Western Hemisphere** and **Europe/Mediterranean** (with the exception of **Turkey** and **Yugoslavia**) were found to have a much closer language and religion association with the U.S.

CULTURAL FACTORS: LANGUAGE AND RELIGION

FACTORS	A	B	C	D
LANGUAGE	ENGLISH	SPANISH/FRENCH *	ARABIC	ALL OTHERS
RELIGION	CHRISTIAN	CHRISTIAN ORTHODOX	EASTERN/ TRIBAL/ISLAM	ISLAM
NUMBER OF EXPEDITIONARY ENVIRONMENT COUNTRIES	6	22	30	7

* ALSO INCLUDES GREEK, ITALIAN, DUTCH, PORTUGUESE, DANISH, NORWEGIAN, AND TURKISH

CULTURAL FACTORS: LANGUAGE AND RELIGION

	A	B	C	D
WESTERN HEMISPHERE	GRENADA JAMAICA	COLOMBIA COSTA RICA CUBA DOMINICAN REPUBLIC EL SALVADOR GUATEMALA HAITI HONDURAS MEXICO NICARAGUA PANAMA PERU SURINAM VENEZUELA

EUROPE/MED		DENMARK GREECE ITALY NORWAY	TURKEY YUGOSLAVIA	

PLANNING AND PROGRAMMING IMPLICATIONS

Language and religion are two major elements of the "cultural" terrain within which the MAGTFs must conduct stability operations and limited objective operations. Both require intense interaction with the civilian populace during the operation. The good news is that a MAGTF with strong Spanish and French language skills can operate in 79% of the countries studied, as English, Spanish, or French are established as second languages. Arabic, however, remains a weak point, and is required in fully 30% of the countries of concern. Along with Arabic, an understanding of Islam is critical in 36% of the countries.

Intelligence specialists are not the only ones who need language skills. Low intensity operations require many more Marines in occupational specialties as wide-ranging as military police, engineers, and public affairs to be in language designated billets.

The lack of an active duty PSYOP and Civil Affairs capability may pose a dilemma to MAGTFs needing no-notice support but lacking the authority to mobilize reservists. Religion is an important environmental feature. One product that could be developed by the reserves for contingency use would be a series of distinct Codes of Conduct corresponding to each major religion and related ethnic or racial group likely to be encountered by the MAGTF. Such a series should be no more than one page in length per category, and suitable for issuance to the individual Marine.

CRITICAL WEATHER FACTORS

CRITERIA FOR LEVELS OF DIFFICULTY

	LEVELS OF DIFFICULTY →					
	A	B	C	D	E	F
Weather	Dry/Warm	Wet/Warm	Mixed	Dry/Hot	Wet/Hot	Wet/Cold

F - • Precipitation of 70 inches or more annually
• Temperature of 40 degrees Fahrenheit or below for extended periods

E - • Precipitation of 70 inches or more annually
• Heat index (combined relative humidity and air temperature) of 80 or above for extended periods

D - • Precipitation of 12 inches or less annually
• Heat index of 80 or above for extended periods

C - • Precipitation between 12 and 70 inches annually
• Wide variations in temperature and rainfall throughout a country

B - • Precipitation of 70 inches or more annually
• Temperatures ranging between 40 degrees Fahrenheit and a heat index of 80

A - • Precipitation of 12 inches or less annually
• Temperatures ranging between 40 degrees Fahrenheit and a heat index of 80

Volume II, Study Supporting Material, Section 18, Critical Weather Factors provides tables which show average temperatures, average relative humidity, and average rainfall by country, as well as a rating of overall weather conditions for each country. The references used as source material for this assessment are as follows:

(1) The Weather Almanac, Gale Research Company, 1981
(2) The Weather Handbook, A Summary of Weather Statistics for Selected Cities Throughout the United States and Around the World, Conway Research, Inc, 1974
(3) The New Book of World Rankings, Facts on File, Inc., 1984
(4) World Facts and Figures, John Wiley and Sons, 1989
(5) Worldmark Encyclopedia of Nations, 1984
(6) World Climate Data, Climatic Data Press, 1972

SUMMARY ASSESSMENT OF IMPACT ON EXPEDITIONARY ENVIRONMENT COUNTRIES

The accompanying chart shows the weather conditions associated with the various regions of the world. For operations in **Latin America** and the **Caribbean**, military forces should be prepared for wet and hot conditions, while in the **Middle East** and **Southwest Asia** dry and hot conditions prevail.

Africa presents a variety of conditions including some of the most challenging. **Asia** and the **Pacific** are primarily wet and hot or to a lesser extent mixed, while **Europe** has the most difficult conditions in **Norway**, followed by mixed or variable situations elsewhere.

Within the expeditionary environment, only one country, **Norway**, had wet and cold conditions which are the most difficult to operate in. There were 33%, or 23 of 69 countries with the next most difficult conditions, wet and hot. Countries such as **Colombia, Panama, Liberia**, and the **Philippines** fall within this category.

The next level of difficulty is dry and hot conditions with 24%, or 16 of 69 countries in the expeditionary environment. Countries such as **Libya** and **Angola** are in this grouping. This is followed by countries with mixed or highly variable conditions. Here there are 33% of the total, or 23 countries, including **Cuba** and **Iran**.

The last two types of weather conditions representing the least operational difficulty are wet/warm with 1% and dry/warm with 8%. Examples of countries with these conditions are **Syria** and **South Africa**.

CRITICAL WEATHER FACTORS

	DRY/WARM	WET/WARM	MIXED	DRY/HOT	WET/HOT	WET/COLD

PLANNING AND PROGRAMMING IMPLICATIONS

As indicated by the above figures, the weather in the expeditionary environment is uniformly hot. This suggests that evaluation standards for vertical lift and other systems should be based on "hot" as the norm rather than as the "extreme" condition. **Norway**, and its cold weather conditions is unique among the countries. The cost to the Marine Corps and its MAGTFs in maintaining a cold weather capability for this single contingency may merit review.

GENERAL GEOGRAPHIC CONDITIONS

CRITERIA FOR LEVELS OF DIFFICULTY

	LEVELS OF DIFFICULTY →			
Gen Geographic Conditions	Urban	Desert	Jungle	Mountainous

The most difficult geographic conditions were mountains, followed by jungle, desert, and urban centers. The predominate condition in each country was determined through a review of the reference material. A country was classifed as "urban" if 70 percent or more of its population were living in urban areas. References used for this assessment included:

(1) Countries of the World and Their Leaders Yearbook, 1989, Gale Research Inc.
(2) The World Almanac and Book of Facts, 1989, Published by Pharos Books, a Scripps Howard Company
(3) The World Factbook, 1988. Directorate of Intelligence, Central Intelligence Agency

SUMMARY ASSESSMENT OF IMPACT ON EXPEDITIONARY ENVIRONMENT COUNTRIES

The accompanying charts show a breakdown of country general geographic conditions by regional distribution. In the **Western Hemisphere**, over half the countries have primarily mountainous conditions. Countries such as **Colombia**, **El Salvador**, and **Panama** fall into this most difficult category. Three countries in the region, **Costa Rica**, **Nicaragua**, and **Surinam**, have predominately jungle conditions which are the next most difficult after mountains.

In the **Middle East/Southwest Asia**, almost 60 percent of the countries have desert conditions. These include **Egypt**, **Kuwait**, and **Saudi Arabia**. In this region, **Iran**, **North Yemen**, and **Oman** can be characterized as mountainous. **Bahrain**, **Iraq**, and **Lebanon** have 70 percent or more of their populations living in urban centers.

GENERAL GEOGRAPHIC CONDITIONS REGIONAL DISTRIBUTION

	URBAN	DESERT	JUNGLE	MOUNTAINOUS
WESTERN HEMISPHERE	CUBA		COSTA RICA	COLOMBIA
	MEXICO		NICARAGUA	DOM. REP.
	PERU		SURINAM	EL SALVADOR
	VENEZUELA			GRENADA
				GUATEMALA
				HAITI
				HONDURAS
				JAMAICA
				PANAMA
MIDDLE EAST/ SOUTHWEST ASIA	BAHRAIN	EGYPT		IRAN
	IRAQ	KUWAIT		NORTH YEMEN
	LEBANON	LIBYA		OMAN
		QATAR		
		SAUDI ARABIA		
		SOUTH YEMEN		
		SYRIA		
		UAE		

Africa was found to have a range of conditions. Eight countries such as **Algeria**, **Somalia**, and **Tunisia** have desert conditions, three have jungle (**Liberia**, **Uganda**, and **Zaire**), and four have mountains (**Ethiopia**, **Madagascar**, **South Africa**, and **Zimbabwe**) as their primary features.

In **Asia/Pacific**, just under half the countries had mainly jungle conditions. Representative countries in this category were **Burma**, **Indonesia**, and **Malaysia**. Mountainous conditions prevailed in almost 40 percent of the countries in this region. Countries such as **Afghanistan**, **North Korea**, **South Korea**, and the **People's Republic of China** were in this caregory.

In **Europe/Mediterranean**, **Greece**, **Norway**, **Turkey**, and **Yugoslavia** presented mountainous conditions while Denmark and Italy had mainly urban populations.

				YUGOSLAVIA

PLANNING AND PROGRAMMING IMPLICATIONS

The four types of terrain appear with sufficient frequency to require the development of full combined arms capabilities for each: mountains, jungles, deserts, and urban environments. Scenarios corresponding to each of these different environments would be helpful in developing Required Operational Capabilities (ROC).

OPERATIONAL ELEVATION

CRITERIA FOR LEVELS OF DIFFICULTY

	LEVELS OF DIFFICULTY →					
	A	B	C	D	E	F
OP Elevation	<2000 Ft	<4000 Ft	<6000 Ft	>6000 Ft	>9000 Ft	>12,000 Ft

F - Elevations greater than 12,000 feet

E - Elevations from 9,001 feet to 12,000 feet

D - Elevations from 6,001 feet to 9,000 feet

C - Elevations from 4,000 feet to 6,000 feet

B - Elevations from 2,000 feet to 3,999 feet

A - Elevations from sea level to 1,999 feet

NOTE: In the process of grading each expeditionary environment country, averages were taken of elevations adjacent to coastal areas, capital cities, key installations, important lines of communications, and other areas where Marines would be likely to operate. Data was obtained from reference material, including atlases, encyclopedias, and almanacs.

SUMMARY ASSESSMENT OF IMPACT ON EXPEDITIONARY ENVIRONMENT COUNTRIES

The accompanying matrices show the regional distribution of countries by operational elevation. In the Western **Hemisphere**, half the countries had operational elevations between 2,000 and 4,000 feet. The mountainous country of **Peru** was found to have the highest elevations.

In the **Middle East/Southwest Asia**, almost 80 percent of the countries were grouped in the elevation categories of less than 4,000 feet and less than 2,000 feet. **North Yemen, Iran,** and **Saudi Arabia** had the highest elevations

REGIONAL DISTRIBUTION OF COUNTRIES BY OPERATIONAL ELEVATION

	< 2,000 FT	< 4,000 FT	< 6,000 FT	> 6,000 FT	> 9,000 FT	> 12,000 FT

	EGYPT	LEBANON	SAUDI ARABIA			
	KUWAIT	OMAN				
	LIBYA	SOUTH YEMEN				
	QATAR	SYRIA				
	UAE					

In **Africa**, the operational elevations ranged between 2,000 and 9,000 feet for all countries.

Operational elevations in the countries of **Asia/Pacific** ranged across most of the categories with **Papua New Guinea** presenting the most difficult conditions.

In **Europe/Mediterranean, Denmark** had the lowest elevations while **Greece, Norway, Turkey,** and Yugoslavia had the highest.

REGIONAL DISTRIBUTION OF COUNTRIES BY OPERATIONAL ELEVATION

	< 2,000 FT	< 4,000 FT	< 6,000 FT	> 6,000 FT	> 9,000 FT	> 12,000 FT

	THAILAND					
	VIETNAM					
EUROPE/ MED	DENMARK		ITALY	GREECE		
				NORWAY		
				TURKEY		
				YUGOSLAVIA		

The two expeditionary environment countries with the highest elevations are described as follows:

(1) **Papua New Guinea** contains a complex system of mountains extending from the eastern end of the main island to the western boundary with **Indonesia**. Precipitous slopes, knife-sharp ridges, great outcroppings of mountains to heights of almost 15,000 feet, and broad upland valleys at altitudes of 5,000 to 10,000 feet characterize this area.

(2) In **Peru**, the Andes Mountains occupy nearly 27 percent of the land area and represent a formidable natural barrier to transportation and communications between the coast and the interior. The highest mountain, Huascaran, is 22,071 feet above sea level.

PLANNING AND PROGRAMMING IMPLICATIONS

In preparing for all types of conflict situations, the elevations where Marines will be operating should be a foremost consideration. Particularly in helicopter operations, weather conditions, as well as elevation, must be carefully assessed. The vertical lift of Marines, together with their equipment and supplies, over varied terrain to inland locations is a fundamental requirement for most operations and must receive the careful attention of planners in order to be successfully executed.

CROSS - COUNTRY MOBILITY

CRITERIA FOR LEVELS OF DIFFICULTY

	LEVELS OF DIFFICULTY		
	A	B	C
Cross-Country Mobility	Generally Suited	Partially Suited	Generally Unsuited

C - Large portions of a country are unsuitable for cross-country movement of tracked vehicles due to broken terrain, extensive ground cover, marshes, swamps, and/or significant bodies of water. In those countries where the coastal region prevents tracked movement from the beach to the interior, the entire country is categorized as unsuited for tracked movement.

B - Significant parts of a country are suitable for cross-country movement of tracked vehicles. For example, the **Central Luzon** plain of the **Philippines** is trafficable, while most other parts of the country are mountainous and unsuited for tracked movement.

A - Large parts of a country can accommodate the cross-country movement of tracked vehicles. **Algeria**, for example, is primarily desert and suitable for both wheeled and tracked cross-country movement.

Note: Trafficability in this assessment reflects the suitability for cross-country tracked vehicle movement. The factor did not address lines of communications, and existing road, rail, and canal networks. The emphasis was on true cross-country movement.

The analytical judgments in this assessment are based on a review of each country's National Intelligence Survey or its follow-on Army Country Profile and were developed by the USMC Intelligence Center staff.

SUMMARY ASSESSMENT OF IMPACT ON EXPEDITIONARY ENVIRONMENT COUNTRIES

The accompanying charts illustrate the regional distribution of expeditionary environment countries by suitability for cross-country mobility. Over 60 percent of the countries are generally unsuited for this movement and an additional 20 percent are only partially suited.

In the **Western Hemisphere**, almost 60 percent of the countries were found to be generally unsuited for cross-country movement by tracked vehicles. Countries such as **Colombia, El Salvador, Guatemala**, and Peru have extensive mountain ranges while **Costa Rica, Nicaragua** and **Surnam** have dense tropical forests that preclude vehicular movement. Only in **Cuba, Mexico**, and **Venezuela**, and to a lesser extent **Grenada** can movement be generally accommodated.

GENERAL TRAFFICABILITY/CROSS-COUNTRY MOBILITY

	GENERALLY SUITED	PARTIALLY SUITED	GENERALLY UNSUITED
WESTERN HEMISPHERE	CUBA MEXICO VENEZUELA	GRENADA	COLOMBIA COSTA RICA DOMINCAN REPUBLIC EL SALVADOR GUATEMALA HAITI HONDURAS JAMAICA NICARAGUA PANAMA PERU SURINAM

In the **Middle East/Southwest Asia**, over 40 percent of the countries are generally unsuited for tracked movement. **Iran**, for example, has rugged hills and mountains, and smaller areas of wetlands covering about two-thirds of its area. However, about 60 percent of this region is generally, or at least partially, suited for movement by tracked vehicles. **Egypt** and **Libya** in particular have desert plains which facilitate movement.

Africa was the region with the most countries which could readily accommodate tracked vehicles. Exactly 40 percent of the countries, including **Algeria, Ethiopia,** and **Somalia,** were generally suited for tracked movement while an additional 13 percent (**Madagascar** and **Uganda**) were partially suited. The remaining 47 percent of the countries, including **Angola, South Africa,** and **Sudan,** were generally unsuited due to conditions ranging from forest areas to coastal mountains.

In the **Asia/Pacific** region trafficability presents a serious problem with 13 of 18 countries or 72 percent generally unsuited for tracked movement. The primary impediments to trafficability are dense tropical jungles, numerous wetlands such as swamps and marshes, and periodic heavy rainfall. Only **India** was generally suited and **Afghanistan, Pakistan, the Philippines,** and **South Korea** partially suited for tracked movement in this region.

Of the six **European/Mediterranean** countries considered, four were generally unsuited and two were partially suited for tracked movement. The significant mountain ranges in countries such as **Greece, Turkey,** and **Yugoslavia** were a principal limiting factor in this region.

GENERAL TRAFFICABILITY/CROSS-COUNTRY MOBILITY

	GENERALLY SUITED	PARTIALLY SUITED	GENERALLY UNSUITED
MIDDLE EAST/ SOUTHWEST ASIA	EGYPT LIBYA	BAHRAIN KUWAIT LEBANON QATAR SYRIA UAE	IRAN IRAQ NORTH YEMEN OMAN SAUDI ARABIA SOUTH YEMEN
AFRICA	ALGERIA DJIBOUTI ETHIOPIA KENYA SOMALIA TUNISIA	MADAGASCAR UGANDA	ANGOLA LIBERIA NAMIBIA SOUTH AFRICA SUDAN ZAIRE ZIMBABWE

EUROPE/MED		ITALY TURKEY	DENMARK GREECE NORWAY YUGOSLAVIA

PLANNING AND PROGRAMMING IMPLICATIONS

Marine Corps capabilities which are totally dependent on vehicular transport may need to be reevaluated. It merits comment that a premise which led to these generalizations was that if the coastal region of a country was unsuited, the entire country was assumed to be unsuited because heavy vehicles could not get from their offshore launch point to inland objectives. Maritime Prepositioning Ships (MPS) and strategic airlift deployment alternatives were not considered.

INTERVISIBILITY: AVERAGE LINE OF SIGHT DISTANCE

CRITERIA FOR LEVELS OF DIFFICULTY

	LEVELS OF DIFFICULTY →		
	OPTIMUM	RESTRICTED	POOR
Intervisibility (Line Of Sight)	>2,000 Meters	1,000 - 2,000 Meters	<1,000 Meters

POOR - Average Line Of Sight (LOS) distance is less than 1,000 meters

RESTRICTED - Average LOS distance is between 1,000 and 2,000 meters

OPTIMUM - Average LOS distance is between 2,000 and 3,000 meters.

Intervisibility is defined as the LOS distance that direct-fire weapons (armor and antiarmor) of the ground combat element can fire without restrictions to visibility and weapons effectiveness in each of the expeditionary environment countries. The firepower of armor and antiarmor weapons is highly dependent on the terrain. Long-range, flat-trajectory weapons cannot effectively utilize their range in cities, forests, industrial areas, and mountainous regions. In covered and broken terrain, armored forces can employ only a fraction of their firepower and light infantry forces have the advantage. Darkness, poor weather conditions, and obscurants on the battlefield will also have a limiting effect on long-range, direct-fire weapons. The more open the terrain and visibility becomes, the better these weapons can realize their full potential.

After a close examination of the source material in relation to the above criteria, each of the expeditionary environment countries was rated according to its intervisibility. Volume II, Study Supporting Material, Section 22, Intervisibility: Average Line of Sight Distance contains an assessment of the conditions within each country on which the ratings were based. The references used as source material for the assessment are as follows:

(6) Countries of the World and Their Leaders Yearbook 1989, Gale Research, Inc.
(7) Worldmark Encyclopedia of the Nations, 1984, Worldmark Press Inc.
(8) USMC Intelligence Center document titled Trafficability Narrative.

SUMMARY ASSESSMENT OF IMPACT ON EXPEDITIONARY ENVIRONMENT COUNTRIES

The accompanying matrix shows the regional distribution of countries according to their degree of intervisibility. In the **Western Hemisphere**, over 80 percent of the countries have poor intervisibility where armor and antiarmor weapons cannot be fully employed. Only **Cuba, Mexico,** and **Venezuela** could accommodate better line of sight ranges.

In the **Middle East/Southwest Asia**, more than half the countries had poor intervisibility. The exceptions here were the flat and barren countries of **Egypt, Kuwait, Qatar,** and the **United Arab Emirates**, and to a lesser extent **Iraq** and **Libya** which had better line of sight distances.

In **Africa**, 60 percent of the countries had average line of sight distances less than 1,000 meters. **Kenya** and **Tunisia** could accommodate intervisibility between 1,000 and 2,000 meters while **Algeria, Djibouti, Ethiopia,** and **Somalia** could exceed 2,000 meters.

The great majority of countries in **Asia/Pacific** and **Europe/Mediterranean** fall into the category of poor intervisibility. In the middle category on the matrix, with average line of sight ranges between 1,000 and 2,000 meters were found the **Asian** countries of **India** and **Pakistan** and the **European** country of **Denmark.**

PLANNING AND PROGRAMMING IMPLICATIONS

An overall assessment of intervisibility in the expeditionary environment indicates that almost three quarters of the countries have average line of sight distances less than 1,000 meters. It was determined that on an average, the engagement range for armor and antiarmor weapons was about 900 meters. This means that most of the countries in the expeditionary environment have terrain, vegetation, and/or other conditions of obscuration which would preclude engagements by these weapons at their maximum ranges. As a result, it may not be cost effective to acquire and maintain a sizeable number of these weapons in the Marine Corps inventory if they cannot be fully utilized. Light infantry forces with a minimum of armor and heavy equipment would appear to be better able to operate in the restricted terrain and visibility conditions that were identified in this assessment. Marine planners must continually evaluate the tradeoffs between forces and weapon systems to select those that can be employed most effectively in the anticipated environment.

HYDROGRAPHY - NAVAL GUNFIRE CONSTRAINTS

CRITERIA FOR LEVELS OF DIFFICULTY

	LEVELS OF DIFFICULTY →			
Hydrography - NGF Constraints	Good	Fair	Poor	Unsatisfactory

UNSATISFACTORY: Distance of the 5 Fathom Line from the coast is greater than 24,000 meters

POOR: Distance of the 5 Fathom Line from the coast is between 16,001 and 24,000 meters

FAIR: Distance of the 5 Fathom Line from the coast is between 8,001 and 16,000 meters

GOOD: Distance of the 5 Fathom Line from the coast is 8,000 meters or less

This assessment addresses NGF capabilities and the constraints imposed by hydrographic conditions off the coasts of expeditionary environment countries. For purposes of this evaluation, a U.S. Navy destroyer with an 8.8 meter (29 foot) draft and 5-inch 54-caliber guns was chosen as the representative NGF platform. To determine coastal hydrographic conditions, the Defense Mapping Agency's hydrographic charts were examined to identify the closest distance a destroyer could operate offshore of the countries of interest. Because the water depths and conditions along extended coastlines frequently have significant variations, key locations (adjacent to ports, cities, or key lines of communications inland) where an ATF would be likely to operate were selected, and a reading taken of the average distance of the 5 Fathom Line from the coast. (Distances were calculated only to the beach, not to inland targets.) Distances were then compared with the 24,000 meter maximum range of the destroyer's guns and a NGF rating based on the above scale was assigned to each country. Volume II, Study Supporting Material, Section 23, Hydrography - Naval Gunfire Constraints provides a listing of country key locations selected for a reading of the 5 Fathom Line, DMA chart numbers of charts used, the assessed distance of the 5 Fathom Line from the coast, and the overall country ratings. The primary reference used for this assessment was the Department of Defense, Defense Mapping Agency, Catalog of Maps, Charts, and Related Products, Part 2 - Hydrographic Products

SUMMARY ASSESSMENT OF IMPACT ON EXPEDITIONARY ENVIRONMENT COUNTRIES

The accompanying charts show a regional breakdown of NGF capabilities affected by hydrography. In the Western Hemisphere, most of the countries have conditions favorable to NGF coverage. Only Surinam had unsatisfactory conditions which would prevent the use of NGF.

NAVAL GUNFIRE CAPABILITIES BY REGION

	GOOD	FAIR	POOR	UNSATISFACTORY
WESTERN HEMISPHERE	COLOMBIA	HONDURAS		SURINAM
	COSTA RICA			
	CUBA			
	DOM. REP.			
	EL SALVADOR			
	GRENADA			
	GUATEMALA			
	HAITI			
	JAMAICA			
	MEXICO			
	NICARAGUA			
	PANAMA			
	PERU			
	VENEZUELA			

In the **Middle East/Southwest Asia**, NGF can be employed to various degrees of effectiveness in all the countries. **Iraq** and **North Yemen** were found not to have the poorest conditions.

In **Africa**, hydrographic conditions were not identified as limiting NGF employment. Only against the inland countries of **Uganda** and **Zimbabwe** was it found not feasible to use NGF.

In **Asia/Pacific** there was determined to be a range of conditions. Due to the offshore constraints involved, NGF could not be effectively employed in **Bangladesh, Burma, North Korea,** and the **People's Republic of China**, as well as the inland country of **Afghanistan**. In other countries in this region, NGF could be delivered with varying degrees of effectiveness.

In **Europe/Mediterranean** offshore hydrographic conditions were found to permit satisfactory NGF coverage in all of the six countries considered.

NAVAL GUNFIRE CAPABILITIES BY REGION

	GOOD	FAIR	POOR	UNSATISFACTORY

EUROPE/ MED	DENMARK			
	GREECE			
	ITALY			
	NORWAY			
	TURKEY			
	YUGOSLAVIA			

PLANNING AND PROGRAMMING IMPLICATIONS

The results of this assessment indicate that good NGF coverage is possible in over half of the expeditionary environment countries if a destroyer approaches to its closest point off the beach. However, to execute an Over-The-Horizon (OTH) amphibious assault where the element of suprise is highly important, it is necessary that the NGF platform operate further out to sea and still cover the priority targets ashore. For this type of operation the 24,000 meter range of the 5-inch, 54-caliber gun is no longer satisfactory. To adequately support OTH operations in the future, Marines must encourage and support Navy actions to acquire an NGF weapon with a range of at least 60 nautical miles.

HYDROGRAPHY - COASTAL THREAT CONSTRAINTS

CRITERIA FOR LEVELS OF DIFFICULTY

	LEVELS OF DIFFICULTY →		
Hydrography - Coastal Threat Constraints	US NGF Advantage	US NGF and Threat Equal	Threat Advantage

THREAT ADVANTAGE: Maximum range of threat coastal defense weapons exceeds 24,000 meters

US NGF AND THREAT EQUAL: Maximum range of threat coastal defense weapons is 24,000 meters

US NGF ADVANTAGE: Maximum range of threat coastal defense weapons is less than 24,000 meters

This assessment considers U.S NGF capabilities as compared to the effectiveness of threat surface-to-surface weapons when used for coastal defense. For purposes of this evaluation, the representative NGF platform was again a destroyer with 5-inch, 54-caliber guns positioned off the coast of expeditionary environment countries. The maximum range of the 5-inch, 54-caliber gun was considered to be 24,000 meters. The methodology for this assessment involved gathering data on surface-to-surface weapons of the countries of interest and comparing the longest range weapon with that of the U.S. destroyer's 5-inch, 54-caliber gun. The above scale was used to assign a rating or level of difficulty to each country.

Volume II, Study Supporting Material, Section 24, Hydrography - Coastal Threat Constraints contains a listing of each country's maximum capability weapon, each weapon's maximum range, and the country ratings which were assigned. The primary data source used for this assessment was Jane's Weapon Systems, 1987 - 88.

SUMMARY ASSESSMENT OF IMPACT ON EXPEDITIONARY ENVIRONMENT COUNTRIES

The accompanying charts illustrate a regional breakdown of U.S. NGF versus threat coastal defense capabilities. It was found that the coastal threat may pose a major problem, as 44 percent of the countries considered have at least some capability that exceeds the range of the standard 5-inch gun on most Navy combatants.

In the Western Hemisphere, Cuba, Peru, and Venezuela have a firepower advantage, while Honduras and Nicaragua possess a capability equal to U.S. NGF.

U.S. NGF VERSUS THREAT CAPABILITIES BY REGION

	U.S. NGF ADVANTAGE	U.S. NGF AND THREAT EQUAL	THREAT ADVANTAGE
WESTERN HEMISPHERE	COLOMBIA	HONDURAS	CUBA
	COSTA RICA	NICARAGUA	PERU
	DOM. REP.		VENEZUELA
	EL SALVADOR		
	GRENADA		
	GUATEMALA		
	HAITI		
	JAMAICA		
	MEXICO		
	PANAMA		
	SURINAM		

In the **Middle East/Southwest Asia**, over two-thirds of the countries have a firepower advantage over U.S. NGF. It is particularly noteworthy that unstable countries such as **Iran, Iraq,** and **Libya** fall into this category.

In **Africa**, almost half the countries, including **Algeria, Angola, Somalia,** and **Sudan**, can out-gun the 5-inch, 54-caliber weapon.

In **Asia/Pacific**, seven countries have the advantage in firepower, the most notable of which are **North Korea, the People's Republic of China,** and **Vietnam**. **Thailand** was found to have a capability equal to U.S. NGF.

In **Europe** and the **Mediterranean**, all the countries considered except **Denmark** have the advantage against U.S. NGF.

U.S. NGF VERSUS THREAT CAPABILITIES BY REGION

			YUGOSLAVIA

PLANNING AND PROGRAMMING IMPLICATIONS

This asessment has found that many of the expeditionary environment countries have acquired surface-to-surface weapons which, when employed in a coastal defense role, would give them the advantage over the standard U.S. NGF capabilities. The 24,000-meter range of the 5-inch, 54-caliber gun is inadequate to provide the necessary support for amphibious or limited objective operations. To effectively supress enemy coastal defenses and engage inland targets from an Over-The-Horizon (OTH) location a more capable NGF weapon is needed. Marines must encourage and support Navy actions to obtain an enhanced NGF capability that will support expeditionary operations at a range of 60 nautical miles or more.

MAPPING, CHARTING, AND GEODESY SHORTFALLS

CRITERIA FOR LEVELS OF DIFFICULTY

	LEVELS OF DIFFICULTY →					
	A	B	C	D	E	F
MC&G Coverage	1:50 New	1:50 Old	Some 1:50	MSI Avail	1:250 New	None

F - Countries with no coverage by 1:50,000 or 1:250,000 scale maps or Multispectral Imagery (MSI)

E - Countries with complete coverage by 1:250,000 scale maps (either series 1501 (ground) or 1501A (air)) and map editions all have been produced since 1980. No 1:50,000 scale map coverage or MSI are available.

D - Countries which have current and complete MSI available, but no 1:50,000 scale map coverage

C - Countries with partial coverage by either current or dated 1:50,000 scale maps

B - Countries with complete coverage by 1:50,000 scale maps, most editions of which were produced prior to 1980

A - Countries with complete coverage by 1:50,000 scale maps and all map editions were produced since 1980

Using the above criteria, expeditionary environment countries were classified into the six categories (A through F through research of the data sources. These sources consisted of the following.

(1) Department of Defense, Defense Mapping Agency, Catalog of Maps, Charts, and Related Products.
(2) Telephone conversations with the Earth Observation Satellite Company, Subject: MSI Support for DMA.
(3) Commanding General, Marine Corps Combat Development Command letter 3140 IN 06 dated June 1, 1989, Subject: Marine Corps Concerns--Mapping, Charting, and Geodesy Documents.

SUMMARY ASSESSMENT OF IMPACT ON EXPEDITIONARY ENVIRONMENT COUNTRIES

The accompanying charts show the distribution of Mapping, Charting, and Geodesy (MC&G) coverage by region. Because there was no countries identified with items E (1:250 New) and F (None) at the upper end of the level of difficulty scale, these items were not addressed further in this assessment.

In the **Western Hemisphere**, only four countries had full coverage by the older 1:50,000 scale maps. These were **Cuba, Dominican Republic, Haiti and Jamaica.** Over 50 percent of the countries had partial coverage with 1:50,000 maps while **Grenada, Mexico, and Surinam** had the less effective MSI available.

DISTRIBUTION OF COUNTRIES BY MC&G COVERAGE

	1:50 NEW	1:50 OLD	SOME 1:50	MSI AVAIL
WESTERN HEMISPHERE		CUBA DOM. REP. HAITI JAMAICA	COLOMBIA COSTA RICA EL SALVADOR GUATEMALA HONDURAS NICARAGUA PANAMA PERU VENEZUELA	GRENADA MEXICO SURINAM

In the **Middle East/Southwest Asia** most of the countries had some 1:50,000 scale map coverage. Only **Bahrain** had full coverage with dated 1:50,000 maps, and **Kuwait** and **North Yemen** had just the MSI available.

In **Africa**, there were no countries with full 1:50,000 scale map coverage. Countries in this region were about equally divided between those with partial coverage by 1:50,000 scale maps and those with MSI. Countries such as **Algeria, Liberia, South Africa**, and **Zimbabwe** had partial 1:50,000 map coverage. Representative countries with only MSI were **Angola, Namibia, Sudan**, and **Uganda**.

In the **Asia/Pacific** region there were only two countries, **North Korea** and **South Korea**, with full coverage by dated 1:50,000 scale maps. The remaining countries were equally divided between the partial 1:50 and the MSI available categories. Nations such as **Afghanistan, Pakistan**, and **Thailand** had the partial 1:50 while **Burma, India**, and **Malaysia** were representative of the MSI available category.

In **Europe** and the **Mediterranean**, the countries of **Greece** and **Turkey** presented the most difficult conditions with only MSI available. **Italy** has partial 1:50 coverage while **Denmark, Norway** and **Yugoslavia** had full coverage with the dated 1:50's.

DISTRIBUTION OF COUNTRIES BY MC&G COVERAGE

	1:50 NEW	1:50 OLD	SOME 1:50	MSI AVAIL

ASIA/PACIFIC		NORTH KOREA SOUTH KOREA	AFGHANISTAN INDONESIA JAPAN PAKISTAN PHILIPPINES PRC THAILAND VIETNAM	BANGLADESH BURMA INDIA MALAYSIA PAPUA N. G. S. PACIFIC IS. SPRATLY IS. SRI LANKA
EUROPE/MED		DENMARK NORWAY YUGOSLAVIA	ITALY	GREECE TURKEY

PLANNING AND PROGRAMMING IMPLICATIONS

This assessment has indicated that there are significant shortfalls in MC&G coverage of expeditionary environment countries. Over 85 percent of the countries have only partial 1:50,000 scale map coverage or MSI. As a result of this situation, MAGTF's employed in many of these countries will not have the maps required to conduct effective ground and air operations. To overcome this deficiency, actions must be taken to ensure that the Defense Mapping Agency directs its available resources toward an aggressive large-scale mapping program of Third World countries to support the range of operations across the spectrum of conflict.

AIRFIELDS

CRITERIA FOR LEVELS OF DIFFICULTY

	LEVELS OF DIFFICULTY					
	A	B	C	D	E	F
Airfields	>1/C-5	1/C-5	>5/C-130	2-4/C-130	1/C-130	None

F - Countries with no airfields that are capable of receiving C-130 or larger transport aircraft

E - Countries with only one airfield that can accommodate C-130 or C-141B aircraft. There are no airfields that can receive C-5 aircraft.

D - Countries with two to four airfields that can accommodate C-130 or C-141B aircraft. There are no airfields that can receive C-5 aircraft.

C - Countries with five or more airfields that can accommodate C-130 or C-141B aircraft. There are no airfields that can receive C-5 aircraft.

B - Countries with only one airfield that can receive C-5 aircraft. These countries may have additional airfields that can handle C-141B and C-130 aircraft.

A - Countries with more than one airfield that can receive C-5 aircraft. These countries may also have airfields that can handle only C-141B and C-130 aircraft.

Using the above criteria, in conjunction with a thorough review of source material, the expeditionary environment countries were classified into the six levels of difficulty (A to F). The purpose in this instance was to show the degree of access that a military force might have to a country through its airfields. Volume II, Study Supporting Material Section 26, Airfields contains a listing of the primary airfields in each country, a brief discription of each airfield, and the overall country rating assigned. The principal reference used for source material was the Military Airlift Command, Code DOVF, Airfield Suitability Report, dated August 1, 1989.

SUMMARY ASSESSMENT OF IMPACT ON EXPEDITIONARY ENVIRONMENT COUNTRIES

The accompanying chart shows a breakdown of countries by their capability to receive strategic airlift. Overall, nearly 80 percent of the countries have at least one airfield that can receive C-5s. There are more than one C-5 capable airfields in 50 percent of the countries. Some of the airfields, however, are constrained in such ways as runway condition, ramp space, fuel storage, and other support functions.

In the **Western Hemisphere**, all the countries considered have at least one airfield able to receive C-5 aircraft. Particularly noteworthy are **Colombia** with 3 C-5, 4 C-141B, and 2 C-130 capable airfields, and **Honduras** with 3 C-5 and 7 C-130 capable airfields.

In the **Middle East/Southwest Asia** 10 of 14 countries or over 70 percent of the total, have at least one airfield which will accommodate C-5s. **Saudi Arabia** has 9 C-5 capable airfields while **Iran** has 8 and **Egypt** 6. In this region, **Iraq**, **North Yemen**, and **Qatar** all have the least accessibility to airlift with only one C-141B capable airfield.

Africa has the fewest countries with airfields able to handle large transport aircraft. The six countries of **Algeria**, **Angola**, **Madagascar**, **Tunisia**, **Uganda**, and **Djibouti** are all unable to accommodate C-5s.

In **Asia/Pacific**, 11 of 18 countries have more than one airfield that can receive C-5s and 4 of 18 countries have just one airfield with this capability. Only **Afghanistan** and **Burma** are limited to C-141B capable airfields while no airfields for transport aircraft can be found in the **Spratly Islands**.

In **Europe** and the **Mediterranean**, 5 of 6 countries have more than one C-5 capable airfield. Only **Yugoslavia** has the lesser capability of 4 C-141B capable airfields.

PLANNING AND PROGRAMMING IMPLICATIONS

The information shown here is designed to illustrate the types of airfields available for planning purposes and provide indicators about where accessibility by strategic airlift may be most difficult. It is noteworthy that strategic airlift (the C-5) surfaced as a very viable option for 79 percent of the countries with tactical airlift (the C-130) opening an additional 21 percent of the countries, if third party nations were available as staging areas. Also, in those cases where direct entry into a country through its airfields is constrained, planners will need to consider access via adjacent countries in conjunction with other tactical means of transport such as helicopter and surface lift.

PORTS

CRITERIA FOR LEVELS OF DIFFICULTY

	LEVELS OF DIFFICULTY →					
	A	B	C	D	E	F
Ports	Wide Harbor/ >50' Depth	Wide Harbor/ >40' Depth	>40' Depth	35-39' Depth	25-34' Depth	None

F - Countries with no major ports.

E - Countries having at least one major port with a large, medium, or small harbor, and channel and anchorage depths of between 25 and 34 feet.

D - Countries having at least one major port with a large, medium, or small harbor, and channel and anchorage depths of between 35 and 39 feet.

C - Countries having at least one major port with a small harbor, and both channel and anchorage depths exceed 40 feet.

B - Countries having at least one major port with either a large or medium harbor, and both channel and anchorage depths between 40 and 50 feet.

A - Countries having at least one major port with either a large or medium harbor, and both channel and anchorage depths greater than 50 feet.

MAJOR PORT:

- Accommodates vessels over 500 feet in length
- Channel and anchorage depths of 25 feet or more
- Harbor size of large, medium or small

HARBOR SIZE:

- Determined by the DMA World Port Index
- Based on area, facilities and wharf space

Through application of the above criteria to the source material, the countries of interest were classified into the six levels of difficulty (A to F). The purpose here was to show the degree of access that a military force might have to a country through its ports. Volume II, Study Supporting Material, Section 27, Ports contains a listing of the primary ports in each country; identifies the most accessible ports; briefly describes each port; and provides overall level of difficulty country ratings. The following references were used for source material:

(1) Defense Mapping Agency Hydrographic/Topographic Center, World Port Index, Ninth Edition, 1984
(2) Commander in Chief, U.S. Atlantic Fleet and Commanding General, Marine Corps Combat Development Command, TACMEMO PZ005700-1-88, Deployment of the Assault Follow-On Echelon, June 1988

SUMMARY ASSESSMENT OF IMPACT ON EXPEDITIONARY ENVIRONMENT COUNTRIES

The accompanying chart shows a breakdown of countries by their capability to receive strategic sealift. Overall, it was found that 33 of 69 countries or about 48 percent of the total fall into the top three levels of difficulty. There were 10 countries, or 14 percent, which have no acceptable major ports. Such countries as **El Salvador, Somalia, Oman**, and **Bangladesh** were in this most difficult category. A total of 15 countries, or 22 percent of the expeditionary environment were in the second most difficult category where major ports had channel and anchorage depths of only 25 to 34 feet. Representative countries in this category were **Cuba, Nicaragua, Iraq**, and **Libya**. Channel and anchorage depths below 35 feet are highly marginal for the approach and off-load of strategic sealift such as the Maritime Prepositioning Ships (MPS) and other Military Sealift Command (MSC) shipping. MPS ships have drafts up to 33 feet. Certain types of MSC and U.S. Flag Fleet cargo ships have drafts over 40 feet.

From a regional perspective, the **Western Hemisphere** countries had the fewest suitable ports while Europe and the **Mediterranean** had countries with the most capable ports. Other regions had a fairly even distribution across the levels of difficulty.

PLANNING AND PROGRAMMING IMPLICATIONS

The information shown here is designed to illustrate the types of ports available for planning purposes and provide indicators concerning those countries where accessibility by strategic sealift is most difficult. In the process of rapid mission planning for contingency operations in expeditionary countries, Marine Corps planners must able to examine all avenues of entry, including sea, air, and land and choose the one most effective. Marine Corps wargaming initiatives and other training efforts should be designed to support this process.

KEY INSTALLATIONS

CRITERIA FOR LEVELS OF DIFFICULTY

	LEVELS OF DIFFICULTY →					
	A	B	C	D	E	F
Key Installations	None	Few Sites	Multi Sites	Pipeline	Oil Field	NBC

F - Countries associated with Nuclear, Biological, and Chemical (NBC) weapon possession and production. These countries have NBC production and storage facilities which could present significant industrial complexity in terms of neutralization.

E - Countries with oil as a significant natural resource. These countries have oil fields, off-shore oil recovery facilities, and supporting industrial capabilities.

D - Countries with numerous industrial complexes together with pipelines for crude oil, refined products, or natural gas.

C - Countries with several basic industrial centers in being or under development and moderately capable transportation and communications systems.

B - Countries having an underdeveloped infrastructure with only a few important facilities such as airfields, ports, and communications sites.

A - No installations of military significance.

Using the above criteria, expeditionary environment countries were classified into the six categories (A through F) through research of the data sources. The purpose here was to show the level of industrial complexity which might be encountered by military forces when operating in a country. Key installations may quickly become priority targets or key objectives when a crisis situation develops. Volume II, Study Supporting Material, Section 28, Key Installations depicts the primary facilities in each country and is the basis for the country ratings assigned. The following references were used for source material:

(1) Foreign Area Studies, The American University, Area Handbook Series, 1979 - 1989
(2) Countries of the World and Their Leaders Yearbook, 1989 Gale Research, Inc.
(3) World Almanac and Book of Facts, 1989.

SUMMARY ASSESSMENT OF IMPACT ON EXPEDITIONARY ENVIRONMENT COUNTRIES

The accompanying chart shows the distribution of countries according to their degree of industrial complexity. Overall, there were 17 of the 69 countries, or 25 percent, which were identified as having NBC facilities, the most difficult category. An additional 19 countries or 28 percent, had oil fields and supporting industrial capabilities.

From a regional perspective, the **Western Hemisphere** countries showed a range of key installation categories from **Grenada** and **Surinam** with just a few sites, to **Cuba** with a reported chemical and biological capability.

The **Middle East** countries all had numerous communications and transportation facilities as well as pipelines and oil fields. **Egypt, Iran, Iraq, Libya,** and **Syria** were associated with NBC production or possession.

In **Africa**, there again was a range of countries from **Djibouti** and **Liberia** with just a few less developed facilities to **South Africa** with a reported emerging nuclear capability.

In **Asia** there were ten expeditionary environment countries which reportedly produce or possess various types of NBC weapons. These included **India, North Korea, Pakistan,** and **Vietnam.**

The countries of Europe all had modern communications and transportation facilities, including industrial centers and pipelines. **Greece** and **Norway** had offshore oil extraction facilities.

				YUGOSLAVIA		

PLANNING AND PROGRAMMING IMPLICATIONS

This assessment has indicated that there is a wide diversity of industrial complexity among the countries of interest. Marines must have an understanding of the infrastructure within these countries to be prepared for a range of operations across the spectrum of conflict. Because events frequently unfold very quickly, important facilities in a country can suddenly become key objectives for peacetime contingency or counterterrorist operations. NBC weapons producing facilities may need to be rapidly seized and secured without adverse affect. Ports and airfields may need to be neutralized and then rapidly repaired so they can be used by friendly forces. Noncombat equipment, material, and replacement parts will all be required to complete this process satisfactorily. Marine planners must ensure that equipment acquisition and training actions are taken to achieve the maximum level of readiness for these situations. Marines, and especially their engineers, must know how such facilities are constructed, what key nodes are within the facilities, and how to protect, destroy, or covertly neutralize the facility.

STRATEGIC AND TACTICAL LIFT CAPABILITIES AND CONSTRAINTS

CRITERIA FOR LEVELS OF DIFFICULTY

	LEVELS OF DIFFICULTY			
	A	B	C	D
MEU Response Time	<2 Days	>2 - <4 Days	>4 - <6 Days	>6 Days

D - Countries which require more than 6 days deployment time for a sea-based MEU.

C - Countries which require between 4 to 6 days deployment time for a sea-based MEU.

B - Countries which require between 2 and 4 days deployment time for a sea-based MEU.

A - Countries which require less than 2 days deployment time for a sea-based MEU.

GUIDELINES

(1) The focus was on typical response times for forward-deployed MEUs and garrison MEUs on the U.S. east and west coasts. The Air Alert Force (AAF) and two Air Contingency Battalions (ACBs) were recognized as a capability to deploy Marines by strategic airlift to any location in the world within 24 hours. However, because neither the AAF nor the ACBs possess a forcible entry capability, they were not factored into this assessment.

(2) The Atlantic Amphibious Ready Group (ARG) with an embarked MEU normally operates in the Mediterranean Sea. The Pacific ARG with its embarked MEU operates either in the Middle East/Southwest Asia region or the Western Pacific based on intelligence reports and the anticipated threat. An assumption was made that there would be some advance warning of a developing crisis to allow initial movement of the ARGs toward an objective area.

(3) Garrison MEUs at Camp Lejeune and Camp Pendleton both require 72 hours to embark aboard amphibious ships. Once embarked, it would require 3 more days for the Atlantic coast MEU to reach the Caribbean Sea and the Pacific coast MEU to reach the southern part of Mexico.

(4) ARGs, once underway, would maintain a speed of 12 knots.

Using the above methodology in conjunction with the data sources, the countries of interest were placed in the four categories (A through D). The following references were used as the basis for this assessment.

(1) Defense Mapping Agency, Hydrographic/Topgraphic Center, Distance Between Ports, Fifth Edition, 1985.
(2) MAGTF Warfighting Center letter dated 13 November 1989, Subject: Deployment Capabilities Guidelines.
(3) Headquarters U.S. Marine Corps, Marine Air-Ground Task Force Master Plan, dated 7 July 1989.

SUMMARY ASSESSMENT OF IMPACT ON EXPEDITIONARY ENVIRONMENT COUNTRIES

The accompanying charts show the regional distribution of expeditionary environment countries according to their respective sea-based MEU response times. In the **Western Hemisphere**, most of the countries require in excess of 6 days deployment time. Only a portion of **Mexico** and **Cuba** can be reached in less time. This is due to the time necessary for garrison MEUs on the **U.S.** east and west coasts to embark on amphibious ships and sail to these countries. In the **Middle East/Southwest Asia**, however, ARG/MEU arrival times at most countries are less than 2 days. These countries are mainly on the Mediterranean Sea and Persian Gulf littoral and are in proximity to the principal ARG/MEU operating areas. In **Africa**, over half the countries required a response time or more than 6 days. These countries are outside the Mediterranean Sea and the farthest away from the ARG/MEU operating in the Indian Ocean. In **Asia/Pacific**, response times were calculated from a likely ARG/MEU operating area in the **Philippines**. Those countries most distant from the **Philippines** had the longest response times. In **Europe/Mediterranean**, the countries of **Norway** and **Denmark** had the longest response times for the ARG/MEU operating primarily in the Mediterranean Sea.

DISTRIBUTION OF COUNTRIES BY ARG/MEU RESPONSE TIMES

	< 2 DAYS	> 2 < 4 DAYS	> 4 < 6 DAYS	> 6 DAYS
WESTERN HEMISPHERE		NORTH MEXICO	CUBA MID-MEXICO	COLOMBIA COSTA RICA DOM. REP. EL SALVADOR GRENADA GUATEMALA HAITI HONDURAS JAMAICA SOUTH MEXICO NICARAGUA PANAMA PERU SURINAM VENEZUELA
MIDDLE EAST/ SOUTHWEST ASIA	BAHRAIN EGYPT IRAN IRAQ KUWAIT LEBANON LIBYA OMAN QATAR SAUDI ARABIA SYRIA UAE	NORTH YEMEN SOUTH YEMEN		
AFRICA	ALGERIA TUNISIA	DJIBOUTI	KENYA MADAGASCAR SOMALIA	ANGOLA ETHIOPIA LIBERIA NAMIBIA SOUTH AFRICA SUDAN UGANDA ZAIRE ZIMBABWE
ASIA/PACIFIC	COASTAL INDIA COASTAL PAKISTAN PHILIPPINES SPRATLY IS.	INLAND INDIA INDONESIA MALAYSIA INLAND PAKISTAN PAPUA N. GUINEA COASTAL PRC SRI LANKA THAILAND VIETNAM	BANGLADESH BURMA SOUTHERN JAPAN INLAND PRC SOUTH KOREA S. PACIFIC IS. (SOLOMON IS.)	AFGHANISTAN NORTHERN JAPAN NORTH KOREA S. PACIFIC IS. (FIJI, KIRIBATI, VANUATU)
EUROPE/MED	GREECE ITALY TURKEY YUGOSLAVIA		DENMARK	NORWAY

PLANNING AND PROGRAMMING IMPLICATIONS

This assessment has found that 42 percent of the countries have ARG/MEU response times of more than six days. This suggests that the Commandant's recent emphasis on strategic deployment by air merits in-depth planning and programming support. In the area of tactical lift, capabilities such as the Landing Craft Air Cushion (LCAC) will allow a naval expeditionary force to be far offshore and still effectively strike a target. The CH-46 helicopter, however, does not have the extended range to adequately support the OTH assault and a replacement such as the MV-22A Osprey needs to be acquired. By using tactical lift capabilities such as the Advanced Assault Amphibious Vehicle, high-speed LCAC, and extended-range vertical lift, the ATF will have a better opportunity to execute its OTH assault.

NONCOMBATANT EVACUATION LOGISTICS

CRITERIA FOR LEVELS OF DIFFICULTY

	LEVELS OF DIFFICULTY →					
	A	B	C	D	E	F
NEO						
Embassy Staff	<25	<50	<100	<250	<500	>500
Evacuees	None	<100	<200	<300	>300	>500 *
Inland Obj	Coastal	<100 NM	<300 NM	>300 NM	>500 NM	>999 NM

* For purposes of this study, 500 evacuees was used as a threshold. Anything above 500 would probably require consideration of other options, i.e., evacuation by airlift or sealift.

F - U.S. Embassy staff over 500; evacuees over 500; and evacuation site 1,000 nm or more from the coast.

E - U.S. Embassy staff - 250 to 500; evacuees - 300 to 500; and evacuation site 500 to 1,000 nm from the coast.

D - U.S. Embassy staff - 100 to 250; evacuees - 200 to 300; and evacuation site 300 to 500 nm from the coast.

C - U.S. Embassy staff - 50 to 100; evacuees - 100 to 200; and evacuation site 100 to 300 nm from the coast.

B - U.S. Embassy staff - 25 to 50; evacuees - up to 100; and evacuation site up to 100 nm from the coast.

A - U.S. Embassy staff less than 25; no evacuees; and evacuation site located on the coast.

EMBASSY STAFF: This includes the Country Team and supporting units such as the Marine Security Guard. Not included are Foreign Nationals who under some circumstances would require evacuation.

EVACUEES: These are the U.S. citizens (less military personnel and U.S. Embassy staff) in residence.

INLAND OBJECTIVE: The capital of each country was selected as the NEO inland objective (evacuation site). Distances were calculated from a point just off the coast to the capital.

Using the above criteria in conjunction with source material, the countries of interest were assigned a rating (A through F). Because a number of countries did not always match the designated categories for Embassy Staff, Evacuees, and Inland Obj, the highest value for the three categories determined the rating. For example, if the country's evacuees exceeded 500 but the inland objective was less than 200 nm from the coast, an "F" rating was assigned. Volume II, Study Supporting Material, Section 30, Noncombatant Evacuation Logistics contains the data for each country on which the ratings are based. The following references were used as source material:

(1) U.S. Department of State, Statistics on U.S. Embassies in Countries of Interest, 21 February 1990.
(2) U.S. Department of State, Numbers of U.S. Citizens Living in Countries of Interest, 21-22 February 1990.

SUMMARY ASSESSMENT OF IMPACT ON EXPEDITIONARY ENVIRONMENT COUNTRIES

The accompanying chart shows the regional distribution of countries according to noncombatant evacuation logistics. In the **Western Hemisphere**, over 80 percent of the countries fell into the most difficult category due primarily to the large number of potential evacuees.

In the **Middle East/Southwest Asia**, all but two countries were rated in the three most difficult categories. There were 9 of the 16 countries in this region that had more than 500 potential evacuees while 5 countries had distances to their capitals (evacuation points) exceeding the range (70 nautical miles) of the CH-46 medium lift helicopter.

In **Africa**, over half the countries presented the most difficult logistic conditions for NEO. Nine of the 15 countries in this region had evacuation distances greater than the range of the CH-46.

In **Asia/Pacific** a total of 12 countries were in the most difficult category while in **Europe/Mediterranean** all 6 countries were rated most difficult. These two regions had 7 countries where distances to the evacuation point exceeded the range of the CH-46. There were 18 countries in these regions with more than 500 evacuees.

PLANNING AND PROGRAMMING IMPLICATIONS

Despite the emphasis in recent years on the importance of the MAGTF in NEO, the study found that these operations are extremely difficult in 53 of the 69 countries (77%) unless there is a major draw-down of U.S. citizens before the crisis develops, or provisions are made for the use of strategic airlift to evacuate the noncombatants. The existing range and lift capability of the CH-46 cannot support the requirements of the expeditionary environment. In most countries, there are over 100 U.S. citizens in the Embassy, and/or over 200 U.S. citizens in the national capital, and/or the distance of the NEO objective from the offshore platform is greater than 300 nautical miles.

APPENDIX G

OSINT OPSEC: Selected References and Information

NOTE: The complete addresses for all of the publishers are provided at the end of this handout.

OPEN SOURCES AND TELEPHONE INTERCEPTION

Tom Kneitel, *Tune In On Telephone Calls*, CRB Research (1993)
ISBN: 0-939780-19-4

OPEN SOURCES AND RADIO INTERCEPTION

Monitoring Air Force One- 50 page manual. Published without any reference to the identity of its author nor to the place or date of its publication. Purchased in July, 1994, through an ad placed in *Monitoring Times*.

Tom Kneitel, *Guide to Embassy & Espionage Communications*, CRB Research (1986).
ISBN: 0-939780-06-2

Monthly hobbyist magazine: *Monitoring Times*, Brasstown, NC.

OPEN SOURCES AND EAVESDROPPING

Electronic Eavesdropping Techniques and Equipment, prepared for the National Institute of Law Enforcement and Criminal Justice, Law Enforcement Assistance Administration, U.S. Department of Justice, by Raymond N. Jones. Republished as *Covert Intelligence: Electronic Eavesdropping* by CRB Research. No date listed.

Electronic plans from - *Portfolio of Schematic Diagrams for Electronic Surveillance*, Mentor Publications, Flushing, NY (1979)

OPEN SOURCES AND UNDERCOVER OPERATIONS

E. Roy Slade and James R. Gutz, *The Pretext Book*, Cloak and Data Press, Houston, TX (1991). Available through: The P.I. Catalogue, (512) 928-8190.

Kingdon Peter Anderson, *Undercover Operations; A Manual for the Private Investigator*,

Paladin Press (1988). ISBN: 0-87364-486-7.

I-INTELLIGENCE

OPEN SOURCE INTELLIGENCE TOOLS AND RESOURCES HANDBOOK

I-INTELLIGENCE

OPEN SOURCE INTELLIGENCE

TOOLS AND RESOURCES HANDBOOK

2018

Aleksandra Bielska

Natalie Anderson, Vytenis Benetis, Cristina Viehman

Foreword

I am delighted to share the latest version of our OSINT Tools and Resources Handbook. This version is almost three times the size of the last public release in 2016. It reflects the changing intelligence needs of our clients in both the public and private sector, as well as the many areas we have been active in over the past two years.

No list of OSINT tools is perfect, nor is it likely to be complete. Indeed, such is the pace of change that by the time you read this document some of our suggestions may have been surpassed or have ceased to exist. Regrettably, today's tool might also be tomorrow's vulnerability.

To counter the first problem, we have included a list of toolkits provided by other OSINT practitioners working to improve the state-of-the-art. To manage the second, we recommend that all tools be tested in a secure computing environment whenever possible.

Work on the next iteration of the Handbook has already begun. For now, I hope this version contributes to improving your efficiency and effectiveness as a researcher, analyst, investigator or general OSINT practitioner. Please feel free to share it with your colleagues. To encourage its broadest possible dissemination, we are publishing the Handbook under a Creative Commons CC BY License.

I would like to end by thanking my colleagues at i-intelligence for their efforts in compiling the Handbook. Particular credit is due to Aleksandra Bielska who led the project and has coordinated the inputs from different contributors. I am also indebted to Natalie Anderson of Mercyhurst University for her excellent research and for the time spent checking these links. Kris Wheaton and Brad Gleason from Mercyhurst's Department of Intelligence Studies are also thanked for their support.

Finally, I would like to thank our community of followers on Twitter for sharing their recommendations with us, as well as the many practitioners who have suggested new tools to us while participating in our courses.

Chris Pallaris
Director, i-intelligence GmbH
